Resolved, That there is no provision in the National Code of Medical Ethics in any wise inconsistent with the broadest dictates of humanity, and that the article of the code which relates to consultations cannot be correctly interpreted as interdicting, under any circumstances, the rendering of professional services whenever there is pressing or immediate need of them. On the contrary, to meet the emergencies caused by disease or accident, and to give a helping hand to the distressed without unnecessary delay, is a duty fully enjoined on every member of the profession, both by the letter and the spirit of the entire Code.

But no such emergencies or circumstances can make it necessary or proper to enter into formal professional consultations with those who have voluntarily disconnected themselves from the regular medical profession, in the manner indicated by the preceding resolution.

After these resolutions had been passed in New Orleans, many of the professional men who always persisted in adhering to the code of the American Medical Association, were of the honest opinion that they had, by accepting them, removed every discrepancy of opinion or difference of action on the part of those adhering to either the old or new code. For it is true that the explanatory declaration of Chap. II., Art. IV., Sec. I., exhibits a great resemblance to the New York Code of 1882. For the Medical Society of the State of New York it must be a source of intense gratification to be convinced, by the passing of that declaration, that a few years have sufficed to so change public opinion as to oblige even the American Medical Association to recognize the justness of most of the New York proceedings. Upon this result the New York State Society can but be sincerely congratulated, and the spirit of equity and justice, as displayed by the Committee drafting the explanatory declaration, must be commended.

The expressions of opinion in regard to the wholesome effect of the New Orleans declaration have been very numerous. I am in possession of several letters containing remarks full of satisfaction and hope. A gentleman well and deservedly known in the profession of both hemispheres, and markedly so with us for his allegiance to the code of ethics of the American Medical Association, gave enthusiastic expression to his delight over the satisfaction that declaration must give, and to the hope that the New York Academy of Medicine would give a public utterance in that direction. That would "immediately settle all difficulty about the code, and at once restore peace and harmony in the profession." I had to tell him that the Academy excluded all politics, ethical or otherwise, from its discussions, and that the only societies who could act in the matter were the medical societies of the County and of the State of New York. There the matter then rested, for I believe I was right in excluding it from any consideration in our midst.

Still, while this Academy is no political body, old and new codes, as far as I know being equally represented with us, we are an integral part of the body medical, and the events in the professional world affect our interests and sympathies intensely. Thus we have to regret that the wording of the resolutions of New Orleans is very apt to obscure their meaning. Emergencies are acknowledged to be binding, but while the New York code admits that a physician may (not shall, or must) consult with a legal practitioner in a case of emergency, the explanatory declaration of the Association insists that such a meeting is not a meeting in the usual meaning of the term, and such a consultation "no formal professional consultation."

The differences are rather slight, it is true. If in spite of that the code question is still made a war-cry by some, that fast reminds us of the bloody wars and persecutions directed against former friends because of nominal differences of ecclesiastical opinions in the history of the Church. It is also explained by the intense enmity exhibited under all circumstances by those who have been convinced against their will. In a few instances we have to deal with the zeal displayed by converts, who, after they had greeted the birth of the new code with congratulations, were induced by certain external circumstances to change what they call their minds within the period elapsing between the appearance of two monthly numbers; or—what is still more, shall I say surprising, shall I say sad—there are those who fought the new code because they longed for a fight without caring on what account. A gentleman who edited a sprightly and rattling journal at that memorable time, and voted "the regular ticket," and was by no means gentle toward the new-code men and principles, has convinced and assured me he never read the new code. I believe him. There are others again—their number has been large at all times—whose souls and sensibilities are moved by shibboleths, by single words, provided these words are skilfully handled by shrewd calculation.

> "Just where fails the comprehension
> A word steps promptly in as deputy.
> With words 'tis excellent disputing;
> Systems to words 'tis easy suiting;
> On words 'tis excellent believing;
> No word can ever lose a jot from thieving."
> (Bayard Taylor's "Faust.")

This is the element which in skilful hands determines for a moment the result of meetings, caucuses, assemblies. It is the emotional element, which is swayed by sentiment both false and true, by gesticulating oratory, and by implicit temporary confidence in the veracity and sound motives of its presumed leaders; which, therefore, "takes the specialists of the new-code persuasion by the tops of their heads and cuts their throats," but after all is cooled down by common sense, consciousness, and conscientiousness when left to itself. Such men are in the majority. They are the waves of the ocean, always changing, now smooth and smiling, then turbulent and raving; and still always the same, steady in their general effects; now and then a disturbance, and an injury, but always the eternal source of healthful development. We never cease to bless the ocean even when it is doing its temporary worst. Let us, therefore, not despair of the future peaceful and blissful development of the country or the profession in times of turbulent commotion.

What difference is left unabolished, may be left to itself until acrimony is soothed, and bitterness replaced by kindness. Greater discrepancies than these have been wiped out. When the actions of men will be weighed, their opinions in regard to dogmatic utterances will be disregarded. When deeds are counted, let creeds be tolerated. But let us have patience, all of us; great improvements in the universal conscience do not take place by hard fighting and refuting. Lecky is right when he says that the greatest errors cannot be annihilated; it takes time for them to fade out.

In the face of the explanatory declaration passed in New Orleans, which in its main aspects, I take it, endorses the New York State Society and the spirit of the new code, the majority of those present in the meeting of the American Medical Association were guided into

believing that they must protect a sacred code from infidel invaders. The main complaint was that new-code men had been given offices in the organizations of the International Congress. On p. 101 of the *Journal of the American Medical Association*, you will find the following complaint: "Directly upon the threshold of the most important part of their work a majority of the original committee practically ignored all allegiance to the Medical Association, and assuming an entirely independent attitude, at once placed in the front of their ranks . . . one who was well known to have repudiated the National Code of Ethics." And in a voluminous circular addressed to the State and County Medical Societies, composed almost exclusively of editorials of the *Journal of the American Medical Association*, and signed by the permanent Secretary of the Association and four other gentlemen, the following language is used: "The editorials of the Journal of the Association present the case" (the differences in regard to the proposed organization of the International Congress) "so clearly that there can be no doubt of the duty of the friends of the Association, or of the animus of its enemies. We feel assured that your society will indorse the action of the association, and stand firm in support of the Code of Ethics."

It is, however, fairly understood by this time that the war of the codes is over. In fact it has always appeared to unsophisticated people that the fighting about the code was not reciprocal at all; for, when the New York State Society had settled its code question to its satisfaction and that of the country societies in affiliation therewith, it appears that in them and by them, the subject was not mentioned again except on strong provocation. You remember that it took a great deal of emphasis to relieve even this Academy of the proffered dispute. The code question is dying a great deal more easily than the bloody shirt disappeared from the politics of the country. If it is puffed up as the pivot of the organization of the International Congress, everybody is perfectly aware that this is either a pretext or a grave mistake. I believe it is both. Europeans who were not afraid of admitting laymen and homœopathists, expected to meet, if ever they would consent to cross the Atlantic for an International Congress, the American medical profession. No International Congress must be caught in domestic quarrels, or audaciously kidnapped by a society, or a party, or the faculty of a medical school.

We are presenting a sad spectacle. In our first attempt at welcoming the medical world to our shores we have failed. The humiliation connected with this fact we have to submit to; to trace it to all its causes I cannot undertake here. The least we can do is to admit it; if the task we hoped to accomplish was too much for us, let us try to prepare for the future by attending to those duties of our own which we can perform without hinderance or disturbance.

The affairs of the Academy will require our undivided attention. In many respects we have been very successful indeed. The hall and building in which we meet is practically our own and free of debt. Thus we can look forward again to improve our quarters, enlarge our facilities, and think of securing, in some near future, a fire-proof building for our ever-increasing bibliographical treasures. Our income has increased with our membership. Both, however, require additions. There are many desirable men in the profession whom we ought to carry on our lists for mutual advantage.

The hopes I expressed in my inaugural address a few months ago have begun to be fulfilled. Old sections have been revived, new ones have been formed. I may here assure the gentlemen who have undertaken the task of organizing them, that whatever aid the president and council can give them in their labors, will be freely offered. The sections will not only contribute to the improvement of their own members, but will enhance the interest of the general sessions by the communications coming to them from the sections and the discussions emanating therefrom.

To enable them to begin their work, Article VI. of the constitution had to be altered. That change has been brought about in the manner prescribed by law some months ago. It has also appeared to many fellows that more alterations are required; they have given notice of their desire in this respect, but have been unwilling to come before the Academy with any propositions to make radical changes, though in the manner prescribed by law. Now both the constitution and by-laws may be repealed or amended by a three-fourths vote at a stated meeting, provided notice of the same has been given in writing at a previous stated meeting. But it will prove more satisfactory to guard against any mistake by trusting the work of moving proposals to change our by-laws in the hands of a committee carefully selected for that purpose. Off-hand legislation is always dangerous; it often errs, and always weakens the conservative tendencies which must underlie any political, scientific, or social structure, if it be expected to last. The president expresses the hope that if such a committee be appointed, it will be slow in considering and quick in reporting.

If I be at liberty to state a wish of my own, I should say that one of the articles which require amending is that which refers to the Committee on Medical Ethics. This committee is almost powerless; it has no initiative whatsoever; in every case calling for interference or judgment it has to wait for a charge to be preferred by a fellow; the odium of an accusation falls always on an individual member, whose unselfish interest in the welfare of the Academy or the profession is at once published, as it were, by arraying him personally against the accused. To prefer a charge is thus almost rendered an impossibility. Thus, indeed, our law is more apt to encourage derelictions of ethical duties than to prevent or punish them. Now, I am of the opinion that the interest of an accused member must always be taken into account, but that of the Academy is at least of equal importance. What the District Attorney and the police are in the political and social commonwealth, the Committee on Ethics ought to be in our midst. It ought to be both authorized and directed not to wait for personal charges, but itself watch over the moral welfare of our community. If such an authority be established, the ethically weak would know that he is observed and may be held responsible without a fellow being compelled to draw upon himself odium or revenge.

No society, either political or other, can ever do without a penal code—old or new—thus there is no harm in admitting that the Academy is in need of a Committee of Ethics like any other society. If the number of those who necessitate its existence or interference be but small, so much the better; but the few when not stopped, act as bacilli of moral putrefaction. Human kind is so organized that disease germs will operate rapidly and persistently. A committee on ethics, endowed with the authority to warn and censure in time, without any procrastination, will strengthen the feeble when he feels the first symptoms of struggling against temptation, may frighten the man of harder fibre, who would otherwise rely on his facilities and the difficulties on the part of the committee, and protect the interests of society and the endangered dignity of the profession.

That I speak of no imaginary evil we all know too well. What I said a few months ago of the growing tendency of a few to make the public acquainted with their merits and accomplishments through the columns of the secular press was considered timely, and met with the appreciation of many members of the profession, both old and young, here and elsewhere. I mean to deserve the respect of my peers and superiors in the profession by again directing your attention to the fact that the penny-a-liners of the daily press are being utilized in the interest of, and by, weak-kneed brothers who cannot stand on their own legs, who mistake cheap notoriety for

reputation, and the grin of derision for the smile of approval. The more power is concentrated in commerce, the greater the prevalent which is conquered by trade, the more rampant the spirit of grasping egotism, which is pathognomonic of modern industrial pursuits, the more is it the domain of the liberal professions to approximate their aims to an ideal. Let us not forget that learning by heart the action of medicines, or the working of articulations, or the proper use of an instrument does not exhaust the possibilities of a medical man. The physician requires all that, but beyond that all the characteristics of a man of principle and intellectual and moral culture. Neither can be inculcated by the demands of old or new codes. Still, as a corporation and a profession, we are responsible for the existence of these qualities in our members. It is true we cannot supply ideals to order, nor can we make those whose eyes seek the mire raise their brow to the skies. But such as find it difficult to develop those qualities spontaneously must be taught and aided in acquiring them.

As far as I am concerned, I hope there will be no occasion again to refer to the same subject during my term of service. If there be, I shall repeat my warning. For I take it for granted that when you elected me to the highest office in your possession, you did so both in the belief that your candidate would have opinions and principles of his own, and on the condition that he should do his full duty.

SUCCESSFUL CASES OF PULMONARY PHTHISIS.

By W. H. GEDDINGS, M.D.,

AIKEN, S. C.

Previous to the last two or three decades of the present century pulmonary consumption was almost universally regarded as an incurable malady, and the physician esteemed himself fortunate if he succeeded in ameliorating the condition of its unfortunate victims or in warding off for a short time its apparently inevitably fatal termination.

It was not until the occasional discovery of cicatrices and of calcareous masses in the lungs of persons who had died of other diseases, and in whose organs there were no evidences of any recent deposit of tubercle, that the medical world began to believe in the curability of pulmonary phthisis.

The chief reason for this general scepticism was the inability of the physicians of that time to recognize the disease sufficiently early to admit of treatment with any prospect of success. It is true that Auenbrugger published his great work, "Inventum novum ex percussione thoracis humani, ut signo, abtrusos interni pectoris morbus detegendi," as early as 1761, but it was coldly received, and met with no general acceptation until 1808, when Corvisart translated it into French, and through his high position in the medical world at once secured for its almost forgotten author the somewhat tardy recognition of the great discovery he had made some fifty years before. Eleven years later (1819) Laennec completed the good work begun by Auenbrugger, by publishing his immortal treatise on auscultation. Although greeted with the greatest enthusiasm, many years elapsed before these methods of diagnosis became the common property of the profession, and it has been only within the last fifteen or twenty years that a more thorough system of medical education has placed them to some extent within the reach of the average practitioner.

Instead of waiting, as was formerly the case, for extreme emaciation, exhausting sweats, and profuse expectoration to tell the tale, the modern physician now detects with comparative ease the earliest symptoms of the dreaded disease, and takes measures to stay its progress before it reaches a stage when the best directed treatment will avail but little.

To convey conviction to those who still doubt that phthisis is amenable to treatment, and to encourage those who have been unfortunate in their attempts to master the disease, I publish the following successful cases, selected from a large number that have come under my observation during the last ten years. Some of them are included in my report of cases of phthisis treated at Aiken, S. C., and published in The Medical Record of 1879, 1880, and 1882; but most of them are of more recent date.

Case I. *Hemorrhage, infiltration of right lung; complete recovery.*—A middle-aged clergyman, from Gloucester, Mass., a patient of Dr. Morrill Wyman, of Cambridge. Disease commenced with bronchial catarrh in April, 1878. Has had one slight hemorrhage.

February 1, 1879.—The upper portion of the thorax, on the right side, is much depressed. There is an extensive area of dulness occupying nearly the whole front of the right lung. There is also dulness behind, but not so extensive as in front.

March 7th.—Much improved; cough less, but the expectoration continues profuse. Has a good color; and has gained eight pounds.

March 13th.—Patient looks fresh and ruddy; pulse and temperature all but normal. Expectoration still profuse.

April 9th.—Pulse, 84; temperature, 98⅘°. Cough much less, and the expectoration is reduced to a fourth of what it was a month ago.

April 26th.—Pulse, 84; temperature, 99°. Has continued to improve; has gained four pounds since last examination.

May 20th.—Had an attack of diarrhœa a week ago which caused him to lose six pounds, three of which he subsequently regained. He now weighs nine pounds more than he did when he arrived in Aiken. There is diminished resonance, not amounting to positive dulness, extending from the clavicle to the third rib; over which region the respiration is normal, the expiration being barely audible. He coughs little except in the morning, at which time he expectorates two or three drachms of muco-purulent matter. I saw this case again in 1881. He had enjoyed good health since May, 1879, but, being of a very nervous disposition, refused to allow me to examine him. At present (1885) he is still free from pulmonary disease.

Case II. *Pertussis, followed by infiltration of right lung; improvement, relapse, and subsequent recovery.*—A bright little girl of six or seven years, Portsmouth, N. H., who, being under the care of a homœopathic practitioner, consulted me only occasionally, so that her case-history is more or less imperfect. The disease was the result of an attack of pertussis.

November 6, 1878.—Pulse, 120; temperature, 99⅘°. The right lung is infiltrated from the apex to the fourth rib, as evidenced by distinct dulness both[1] in front and behind. The patient did remarkably well until February 1st, when she had an attack of bronchial catarrh. She recovered readily from this, and continued to improve until late in the spring, when she returned home. She spent the summer at North Conway, N. H., and returned to Aiken in 1879. She had had no relapse, and enjoyed good health throughout the winter. She continued quite well until the fall of 1883, when she was attacked with acute pneumonia at her home in Portsmouth, N. H. This was followed by a return of the old symptoms, for the relief of which her mother consulted another physician. Feeling dissatisfied with the progress of the case she called me in again in March, 1883. She was pale, sallow, and emaciated, and although now ten years old, weighed only fifty-six and three-fourth pounds. Her pulse was 104; temperature, 102.5°; appetite bad, digestion poor, with troublesome cough and profuse night-sweats. Physical examination revealed absolute dulness

[1] The symptoms afforded by auscultation were accidentally omitted.

from the right clavicle to fourth rib, with diminished resonance below. Posteriorly the dulness reached to one inch below the spine of the scapula. Respiration on that side bronchial, with prolonged experium and increased vocal resonance.

April, 1885.—Patient has had no relapse since 1883, looks well, and only coughs when she has an acute attack of bronchial catarrh. Pulse and temperature have been normal for over a year. There is marked depression of the diseased side, over which there is still more or less dulness.

Case III. *Profuse hemorrhage, disease of right lung; complete recovery.*—A middle-aged mulatto, one of my own patients, first presented himself about fifteen years ago. He was having quite a profuse hemorrhage from the lungs. The attacks of hæmoptysis continued to recur at longer or shorter intervals. A physical examination afterward revealed dulness and other signs of infiltration of the right lung. The patient, believing that his hemorrhages were due to malarial poisoning, made repeated applications for life insurance, but was invariably rejected. There has been no return of the bleeding since 1874; the cough has ceased, and the patient's general appearance is that of a person in good health. The only physical signs remaining at this date (June 1, 1884) are slight dulness under the right clavicle and first rib, with some feebleness of the respiratory murmur. The patient's trade is that of a tailor, a fact worthy of note in a case in which recovery has taken place; that occupation being justly regarded as decidedly conducive to the development of pulmonary phthisis. So extensive is its prevalence in Vienna among that class of workmen that it is sometimes designated as "the disease of the tailors." This patient has enjoyed perfect health ever since, and is now as fat as a seal.

Case IV. *Hæmoptysis, night-sweats, infiltration of left apex; complete recovery.*—Male, forty-one years of age. Patient of Dr. Van Bibber, of Baltimore. Hereditary predisposition to consumption on the father's side. Disease began with bronchial catarrh in the autumn of 1877. Has had several attacks of blood spitting, and suffers with occasional night-sweats. The patient has been some time in Aiken, and is in much better condition than when he arrived, having gained at least five pounds.

April 4, 1878.—The patient has continued to improve, having gained three additional pounds during the past month, making a total increase of eight pounds since his arrival in Aiken. There has been no return of the bleeding.

April 6th.—His appearance is that of a perfectly healthy man. He coughs occasionally throughout the day, and expectorates about half an ounce, mostly mucus.

Patient has been two months in Aiken, and during that time has gained ten pounds. Pulse and temperature normal. The only physical symptom of the old disease is diminished resonance under the clavicle. This patient may be regarded as nearly well. He has had no relapse since 1878, enjoys perfect health, and has resumed his business in Baltimore.

Case V. *Infiltration of left lung; complete recovery.*—A young girl, fifteen years of age, from Cincinnati (Drs. Carson and Richards). Disease commenced with cough on March 7th.

April 17, 1878.—Pulse, 96; temperature, 101°. Left side dull in front, from the clavicle to second or third rib; respiration feeble and indistinct in character. On the right side the respiration is louder, with audible expiratory murmur.

April 24th.—Improving; coughs very little, and then only in the morning.

July 8th.—Pulse, 88; temperature, 98¾°. Cough has disappeared entirely, and the patient presents all the appearances of a person in perfect health. Notwithstanding her having several sharp attacks of diarrhœa, her weight has increased from 135 to 145½ pounds. This young lady has remained quite well, and up to 1883, when last heard from, was in the enjoyment of perfect health.

Case VI. *Disease of right lung, improvement, relapse, and subsequent recovery.*—Male, forty years of age, from Worcester, Mass.; patient of Dr. Calvin Ellis, of Boston, and Dr. Thomas Gage, of Worcester. Began with bronchial catarrh in January, 1879. Has gained three pounds since his arrival in Aiken, thirteen days ago.

April 22, 1879.—Color good; if anything, too florid. Expectorates one ounce of muco-purulent matter; pulse, 108; temperature, 101¼°. Dull on the right side, from the clavicle to the second rib in front, and as low as the angle of the scapula behind.

April 30th.—Continues to improve, coughs less, and the expectoration is somewhat reduced in quantity.

May 18th.—Patient does not look so well, and there are indications that the disease is extending.

May 22d.—Color bad, apparently losing ground very rapidly. Area of dulness extends in front to the lower border of the third rib. Has an obstinate diarrhœa, resisting for a long time all the usual remedies. This was eventually checked and the patient went back to his home in Vermont, where he slowly improved. Returned to Aiken the following winter.

November 12, 1880.—Pulse, 80; temperature, 99°; weight, 137½ pounds. Coughs three or four times in twenty-four hours, raising each time a small quantity of muco-purulent matter. Dull on the right side from above clavicle to the upper border of third rib, and between the scapula and vertebral column, the respiration being bronchial in character.

December 10th.—Has continued to improve. Pulse and temperature are normal, and his weight has increased to 140½ pounds, a gain of three pounds since October 12th. Cough has ceased almost entirely, a little hack after breakfast being all that is left of it.

January 10, 1881.—Improvement has continued without interruption; has not missed a meal since his arrival in Aiken; has attained his full average weight, and presents the appearance of a person in perfect health.

Right side: The dulness in front extends now only to the lower border of the first rib; posteriorly it remains unchanged. Respiration slightly bronchial.

April 24th.—Notwithstanding several weeks' confinement to the house with an old gunshot wound, the patient has continued to improve. The little hack in the morning, noted at the last examination, has disappeared, and for six weeks there has been no cough of any description. Pulse and temperature remain normal. There has been no further change in the physical symptoms, except diminution of the area of dulness behind, which is now confined to the space above the spine of the scapula, and between that portion of the bone and the column.

The above is the most remarkable case of arrest of phthisis that has ever come under my observation. At one time, in the spring of 1879, he was so pale, and the temperature so persistently high, that a fatal termination appeared to be inevitable. He has remained perfectly well ever since, and is now established in business in Tennessee. Has since been accepted by an insurance society.

Case VII. *Infiltration of left lung, night-sweats, emaciation; recovery.*—A young man, twenty-four years of age, from Burlington, N. J., a patient of Dr. Grant. Does not know whether there is any hereditary predisposition to consumption in his family. He began to cough in July, 1879, and shortly afterward had a slight hemorrhage, which, in its turn, was succeeded by night-sweats and loss of flesh. He has lost in all twenty pounds, his present weight being 120 pounds.

October 20, 1879.—Color pale; pulse, 112; temper-

ature, 100.2°. Expectoration muco-purulent in character and small in quantity.

Left side: There is dulness in front, from the clavicle to the heart, and behind, from the upper border of the scapula to its lower angle. The respiration over the front is bronchial in character, with prolonged experium; posteriorly the respiratory murmur is indistinct.

Right side normal, except that the respiration over the apex is harsh, with prolonged experium.

November 3d.—Pulse, 108; temperature, 100.2°. Looks much better, is stronger, has gained five pounds in two weeks, and the sweats have ceased entirely.

November 20th.—Pulse, 100; temperature, 99.5°. Weight 130 pounds, a gain of ten pounds during the month.

December 8th.—Pulse, 98; temperature, 99°. Has continued to improve, looks well, and coughs but little. Weighs 132½ pounds, a gain of twelve and a half pounds.

January 10th.—Pulse, 96; temperature, 99°. Looks fresh and ruddy, and has the appearance of a person in good health. His present weight is 136 pounds, a gain of sixteen pounds since his arrival in Aiken. Coughs only once in three days, on which occasions he expectorates only a little pellet of mucus.

March 8th.—Color rosy; never coughs except after some unusual exertion, such as a fit of laughter. The area of dulness in front has become more resonant, especially below the clavicle and near the sternum. The dulness now does not extend lower than the third rib. Behind, the dulness reaches from the spine of the scapula to its lower third, the region above the spine and the lower third having become resonant. The respiration is no longer distinctly bronchial, but rather undecided in its character.

This case was lost sight of after his return home, and I am therefore unable to state whether the results obtained were permanent.

Case VIII. *Infiltration of right lung; no return of symptoms for fifteen years.*—H. B——, colored, female, about fifty years of age. This patient consulted me in 1870, on account of persistent cough and loss of flesh, accompanied with slight fever. Physical examination revealed consolidation of the upper third of the right lung. She gradually regained flesh and strength, the cough disappeared, and with it the other symptoms of pulmonary disease. She has remained well ever since, and has been able to resume her usual work.

December 31, 1879.—Ten years have elapsed since her first examination; there has been no return of cough or of any other symptom of lung disease; the pulse is somewhat accelerated (92), but there is corresponding rise of temperature. The only trace of the disease present is an area of dulness on the right side, extending from above the clavicle to the upper border of the second rib. She has had no threat of the return of the old disease, and, although well advanced in years, is able to do a full day's work as a washerwoman.

At the present date, 1885, the patient is in the enjoyment of perfect health.

Case IX. *Infiltration of right lung, hemorrhage, fever, night-sweats, emaciation, etc.; complete recovery.*—Male, twenty-five years of age; from Malden, Mass.; patient of Dr. Bemiss, of Medford, Mass. Heredity on the maternal side, mother and two brothers having died of phthisis. The disease began with a slight attack of hæmoptysis in May, 1878. This was followed with loss of flesh and night-sweats. Had another hemorrhage in April, 1879, much more profuse than the first, and then began to cough. Went to Minnesota, where he for a time ceased to cough. Over-exerted himself, brought on profuse hemorrhages and a return of his cough. The hemorrhages continuing to recur, he started for Aiken.

January 1, 1880.—Pulse, 100; temperature, 100°; weight, 126 pounds; color good.

Right side: Dull from the clavicle to the second rib, with diminished resonance under the third. Respiration bronchial, with jerking expiration. Behind, the dulness extends over the upper two-thirds of the scapula.

There is no dulness on the left side, but the respiration is very harsh. Moist râles over both lungs. Expectorates one-half ounce, some of which sinks. Can now lie on both sides, which he was unable to do during the summer. Prognosis favorable. Patient improved steadily, the temperature sank to 99.5°, and he gained two pounds in weight; the cough became much less troublesome, and the expectoration ceased altogether. During the month of March an abscess formed near the anus, and developed into an exceedingly troublesome and very painful fistula. This prevented any further increase in weight, but seemed to benefit the local symptoms in the lung; the cough ceasing entirely after the opening of the abscess. At the time of his departure he was suffering too much to submit to an examination, but I afterward met him at Bethlehem, and found him quite well. There had been no return of the cough, and his general appearance was that of a healthy man. Physical examination showed a reduction in the size of the infiltration; the dulness extending in front from below the clavicle to the second rib, while, behind, the only evidence of disease is diminished resonance between the upper portion of the scapula and the vertebral column. The fistula had been operated upon, and was gradually healing. At last accounts (1883) this patient had resumed business in Massachusetts, and was perfectly well, being able to remain at his post as bookkeeper in Boston, even during the winter months.

Case X. *Consolidation of apices of both lungs, emaciation, night-sweats; complete recovery.*—Male, aged twenty-five years of age, from Belleville, Ontario (Dr. M. Sullivan). Disease began in November, 1879, with bronchial catarrh; had night-sweats, and lost fifteen pounds.

January 31, 1880.—Pulse, 102; temperature, 102°; weight, 150 pounds. Was quite ill during the journey south, and had to stop at Baltimore. Color pale. Expectorates about one ounce of muco-purulent matter. Tongue coated; cannot retain food. Right side dull in front, from above clavicle to the fourth rib, with bronchial breathing.[1]

April 12th.—Patient improved steadily after the second week of stay in Aiken, and now looks quite robust; has a fresh, ruddy color, and now weighs 165 pounds, a gain of fifteen pounds since his arrival. Pulse, 80; temperature, 98.5°. Coughs only after a hearty laugh or some other unusual exertion. The dulness on the right side is reduced to a limited area above the clavicle, with diminished resonance under that bone. Behind there is diminished resonance over a small space between the scapula and spinal column. Respiration in front is vesicular, behind bronchial, over a very small area. On the left side the dulness has disappeared entirely, and the respiration is everywhere vesicular.

Result: Complete arrest of the disease, with a gain of fifteen pounds, and entire disappearance of all physical signs of disease in one lung, and partial clearing of the other. When last heard from this patient was living in Canada, and had had no return of the disease.

Case XI. *Infiltration of right lung, hemorrhage; arrest, with cessation of all symptoms of disease except slight dulness on percussion.*—Male, twenty-eight years of age (Dr. George H. Humphreys, New York). Had hemorrhages at long intervals during the summer of 1879, with cough and night-sweats. Lost eight pounds.

February 10, 1880.—Color pale. Expectoration small in quantity, and muco-purulent in character. There is dulness on the right side above, under, and below the clavicle in front, and between the scapula and vertebral column behind. In addition to this there is a limited area of dulness in the axillary line. Respiratory murmur is feeble.

March 10th.—Pulse, 76; temperature, 99.5°. Much

[1] Physical signs on the back were accidentally omitted.

improved, color good. Coughs only in the evening, and without expectorating. Has gained two pounds. There is no change in the physical signs, but over the back and side there is no trace of the dulness observed at the first examination.

May 1st.—Patient has continued to improve, and now presents the appearance of a man in perfect health. Flesh firm, color good. Walks eight miles without fatigue. He has gained two additional pounds, and has no cough. The only evidence of disease left is slight dulness under the right clavicle, with harsh respiration, and audible experium at the apex on that side. During the following winter, 1880–81, he had slight cough, but by spring this was reduced to a mere hack. The ensuing summer was spent in the Adirondacks, where he had a slight hemorrhage. Did well at Aiken the next winter, but in the summer, while at Morristown, N. J., he had another very slight attack of bleeding. Since then he has been free from all symptoms of disease, and is to all appearances a perfectly healthy man.

Case XII. *Disease of upper portion of left lung, hæmoptysis, night-sweats, emaciation; recovery.*—A young lady, twenty-six years of age, a patient of Dr. W. W. Johnson, of Washington, D. C. The disease began with cough in September, 1879, followed by loss of weight and hemorrhage in December. Has also had night-sweats. Has lost nine pounds. She arrived in Aiken seven weeks ago and has improved, having already gained eight pounds.

March 2d.—Pulse, 108 (under excitement); temperature, 98½°. Looks quite healthy. Physical examination reveals dulness on the left side extending from the clavicle to the fourth rib, and under the upper portion of the scapula.

April 20th.—The improvement noted above continued until the middle of March, when she was unfortunate in contracting a severe cold, during which she suffered with severe pleuritic pains and lost her voice. Up to that time she had gained twelve pounds. She has now recovered from the attack and is again improving.

Encouraged by her improvement at Aiken, she concluded to remove to Santa Fé, N. M., where she had relatives. Not liking the social aspects of the place, she went to Colorado Springs; but while there a valvular affection of the heart, of which symptoms had been observed at Aiken, became so aggravated by the altitude as to necessitate her removal to the East. She returned to Aiken in January, 1881, with a severe attack of laryngitis. She looked strong and healthy, and although there was still slight dulness below the clavicle, the symptoms of pulmonary disease were evidently at a stand-still. She continued to improve after her return home, where she afterward married. When last heard of, she was quite free from pulmonary disease, although, owing to the cardiac trouble, she still had some cough. This is one of two well-marked cases of phthisis of this series in which the pulmonary disease appeared to have been arrested by the occurrence of valvular lesions of the heart.

Case XIII. *Infiltration of right lung; complete recovery.*—Male, twenty-two years of age. (Dr. J. S. Lothrop, Boston.) Lost a brother with pulmonary phthisis. Disease began in March, 1879, with cough and emaciation. Lost eleven pounds, but subsequently regained eight pounds.

March 13, 1880.—Pulse, 84; temperature, 98½°; weight, 125 pounds. Expectoration small in quantity, and of late occasionally streaked with blood. Over right front dulness above and under the clavicle. Respiration feeble, with prolonged experium. Behind there is dulness under the supraspinous fossa, the respiration being as in front.

April 23d.—Patient has had an exacerbation of his disease, with fever, pleuritic pain, and a loss of four pounds in weight. From this he soon rallied and now weighs 128 pounds, which is three pounds more than at the time of his arrival. The infiltration is slightly increased in size, there being diminished resonance to the second rib in front, and two-thirds down to scapula behind.

He was again under my care during the summer at Bethlehem, N. H., where his improvement was rapid and continuous. He afterward engaged in farming in Southern California, but tiring of the life, returned to New England. I had an opportunity of examining him in Aiken in the winter of 1885, and found him in perfect health.

Case XIV. *Slight consolidation of right lung, tinged sputa, night-sweats, emaciation; complete recovery.*—A young lady, twenty-eight years of age, a patient of Dr. Opie, of Providence. Several relatives on the maternal side, including the patient's mother, have died of phthisis. Had cough during the winter of 1878 and 1879, but was free from it during the ensuing summer. It returned again in the fall after an attack of "nervous prostration," and has persisted ever since. Has lost a great deal in weight, but does not know how much. Sputa have been occasionally tinged, and has also suffered with night-sweats. Has improved a great deal since her arrival in Aiken six weeks ago, eating and sleeping well, increasing in weight, and coughing less.

April 17th.—Pulse, 100; temperature, 99.5°; weight, 90 pounds; expectorates half an ounce. Over the right front, which is very sensitive on percussion, there is no marked dulness, but the respiration is decidedly bronchial. Posteriorly there is dulness under the scapula and between that bone and the column. The respiration over that region is bronchial.

May 5th.—Pulse, 80; temperature, 99.8°. Has gained eight pounds and has a healthy color. Coughs but little, and does not expectorate more than a drachm. (I did not have an opportunity of examining her before she left Aiken, but on meeting her a few months later at Bethlehem, N. H., I found she had been entirely free from cough for several months. The bronchial respiration had disappeared, leaving only a little roughness. The area of dulness behind, although still present, was much more limited than when I first examined her.) She afterward married, and is now quite well.

Case XV. *Extensive infiltration of the base of the right lung, fever, sweats, and rapid emaciation; complete recovery.*—A young man, nineteen years of age. (Dr. F. P. Porcher, Charleston, S. C.) Father died of phthisis. Had in August, while residing in a malarial region, on the coast of South Carolina, what was supposed to be remittent fever, but which was attended with cough, sweats, and rapid emaciation. On his arrival in Charleston, was examined by Dr. Porcher, who is reported to have pronounced it to be a case of pulmonary infiltration, with pleural effusion. His temperature has ranged from 101° to 103°, with occasional chills, without any regularity in their occurrence.

September 24th.—Pulse, 88; temperature, 102°. Has persistent cough, with muco-purulent sputa. On the right side there is dulness in front, extending from one inch below mamma to the liver. The superior border of this area of dulness extends across the axilla to a point corresponding to the angle of the scapula. The percussion sound is decidedly dull, but not flat, as in pleuritic exudation, nor does change of posture cause any alteration in the character of the dulness. Intercostal spaces well defined, and without the bulging observed in fluid exudations. I accidentally omitted to note the character of the respiration, but remember that the respiratory murmur was distinctly audible, although more faintly so than on the left side. During October the fever gradually declined, and toward the middle of the month the cough abated, and finally ceased altogether. The area of dulness remained unchanged, but there was a marked improvement in his general health, his weight rapidly increasing from 119 pounds on the 19th to 131½ pounds on the 28th, a gain of twelve and a half pounds in nine days, or at the rate of over a pound a day.

November 19th.—Pulse, which has hitherto ranged from 104 to 112, is now only 88, and the temperature has declined to 99°. He eats enormously, and his weight has steadily increased, being to-day 147 pounds, a gain of twenty-eight pounds in one month. The dulness in front is unchanged, but behind it has dropped to a line one inch below the angle of the scapula. The respiratory murmur over the region of dulness is feebler than on the left side. From this time to the date of his departure there was but little change in his condition, except a gradual diminution in the extent of the dulness. When last examined (May), the upper border of dulness in front had receded to the seventh rib, while behind it had disappeared entirely.

Remarks: The rapid improvement of the patient and the rather unusual location of the dulness would at first sight lead one to suppose that the diagnosis of phthisis in this case was incorrect, and that it was either a pleuritic exudation or some disease of the liver. The fact that the dulness, although well marked, was by no means flat, and that the respiratory murmur, noted as feeble, was, nevertheless, audible over the whole of the base of the lung, are sufficient to exclude any fluid accumulation, or any great enlargement of the liver or tumor of that organ. Besides this, the location of the dulness was not influenced by change from the erect to the recumbent posture. There was no icterus or any other evidence of hepatic disease. This patient has had no relapse and is now (1885) quite well.

Case XVI. *Both lungs diseased, consolidation of two-thirds of the right lung with cavity; complete recovery after having been confined to his bed for two months.*—A naval officer, thirty-two years of age, from Norwich, Vt. Family history not noted. On the return of his ship from the tropics, he was exposed to rough, cold weather in New York harbor, which brought on an attack of bronchopneumonia. He lost over ten pounds, and had several hemorrhages.

December 5, 1880.—Pulse, 106; temperature, 101°; weight, 114 pounds. Is very thin, and presents the appearance of a very sick man. There is marked dulness over the whole right lung in front, and posteriorly over the upper two-thirds. In front the respiration is bronchial, except under the second rib where it is distinctly cavernous. On the left side no dulness, but loud, sonorous ronchi, intermingled with moist râles. Cough very troublesome and almost incessant.

February 17th.—This unpromising case, after two months' confinement to his room, during which he suffered terribly with his cough, began to improve about the end of January. His pulse is now 98, and his temperature normal. His color is fresh and healthy; his strength is so much improved that he walks three miles in the course of the day without experiencing any fatigue; and mounts two flights of stairs without becoming short-breathed. Coughs but little, and then only in the early morning, at which time he raises a few pellets of mucus. In front there is no change in the physical symptoms, but behind, the upper portion of the lung has cleared up and is now resonant.

May 26th.—Pulse, 96; temperature, 98.5°. The improvement noted above has continued. Patient looks remarkably well, and is in excellent spirits. He now weighs 125¾ pounds, a gain of eleven and three-fourths pounds; has gradually extended his promenades, and can now walk two miles consecutively. Coughs only a little in the morning, while dressing. The improvement in this case was all the more remarkable on account of its being due to climate alone, as he took neither oil, malt, hypophosphites, or any medicine other than such as was administered to allay his troublesome cough.

The recovery in this case has proved lasting, and the patient has resumed the active duties of his profession. When last heard from he was on duty in the Mediterranean.

Case XVII. *Infiltration of both lungs, fever, hemorrhages; recovery, with a gain of twenty pounds.*—A married man, about thirty-two years of age, a patient of Dr. Riggin Buckler, of Baltimore, who kindly permits me to publish the following extracts from his letters:

"Baltimore, January 25, 1880.

"In 1870 he had trouble at the summit of the right lung; went to China, and returned in 1871 well. The physical signs still show traces of the old disease."

Dr. B. did not see him again professionally until December, 1879, when he sent for him on account of a persistent facial neuralgia, the result of a broken-down condition of health. It was found "that he had been losing weight for some time past, had morning cough, loss of appetite, morning nausea, and shortness of breath. His pulse was quick, 115; temperature, 100°; this at 11 A.M. The dulness over apex of right lung is quite limited, and there are no signs there beyond feebleness of respiration and flattening of the chest-walls. At apex of left lung (upper third) the dulness extends over a greater area. I find increased vocal fremitus, interrupted respiratory movement with feeble and prolonged expiration."

January 29, 1880.—Pulse, 102; temperature, 100.4°; weight, 130 pounds.

February 23d.—Pulse, 102; temperature, 99.2°. Has gained twelve and a half pounds since his arrival in Aiken, and walks six miles by the pedometer without experiencing any fatigue. Coughs and expectorates only in the morning, and has a good color.

March 26th.—Pulse, 96; temperature, 99.3°; weighs 150 pounds, a gain of twenty pounds since his arrival. His general appearance is that of a healthy and robust man. Physical examination reveals a marked diminution of the area of dulness on the left, the lower border of which extends now only to the second rib. With the exception of bronchial breathing at the apex of that side there are no evidences of disease in either lung.

I did not have an opportunity of making another examination, but Dr. Buckler was so kind as to send me the following report of his condition after his return home:

"Baltimore, April 12, 1880.

"W—— arrived Saturday night in the midst of a regular March blow, with the thermometer at 32°. I called on him in the morning, and was more than surprised at his wonderful improvement. His gain in the two months, by actual weight, is twenty pounds, and he has the appearance of a well man. His muscles are hard and firm, voice steady, and his skin has the ruddy hue of health. He tells me that he has *no cough whatever;* that he can breathe freely and easily, and that no amount of exercise fatigues or makes him short-breathed. His appetite and digestion are excellent, and he 'sleeps like a top.' His pulse this morning at 11 A.M. was 80, respiration 24, and temperature, 98°. I find he can expand his chest without pain, and freely and easily. I can find nothing wrong on the right side, and, with the exception of a small area of dulness (with feeble respiration) over the upper and anterior surface of the left lung, I can discover no signs of disease either in that lung. Certainly this shows a marked change as compared with the condition of things when he left this place for Aiken, and speaks volumes in regard to the fitness of the climate there for incipient phthisis. "Very truly yours,

"Riggin Buckler."

This patient had one slight hemorrhage the following winter, but since then has enjoyed good health, and at last accounts was doing well.

Result: Complete arrest of phthisical process, a gain of twenty pounds, disappearance of all physical signs of disease in the right lung, and marked diminution of the area of dulness in the other side.

Case XVIII. *Infiltration of right apex; recovery.*—A young medical student, nineteen years of age, a patient of Dr. A. G. Reed, of Philadelphia. No phthisis

in the family. Cough began in March, 1879, and lasted two months; recurred in June, and continued to September. Visited Mexico with negative results.

December 31, 1879.—Pulse, 78; temperature, 98°; weight, 125 pounds. Figure slender, with sallow complexion. Good appetite, with fair digestion. Right side: dulness over supraclavicular, clavicular, and infraclavicular regions, with diminished resonance to fourth rib. Behind, diminished resonance over the scapular region.

March 27th.—Pulse, 84; temperature, 98°. Has passed through the winter without any return of cough, and has increased six pounds in weight. In front there is now no dulness, and the area of diminished resonance has receded to the second rib; the suprascapular region has become resonant.

Result: Complete arrest of the disease, with a gain of six pounds in weight.

This patient has not been heard from since his departure from Aiken.

(To be continued.)

PERIOSTEUM-GRAFTING.[1]

Reproduction of Two and Three-fourths Inches of the Clavicle in the Human Subject by Grafting with Periosteum and with Thin Laminæ of Bone, Covered by its Periosteum, taken from the Dog.

By C. W. TRUEHEART, M.D.,

GALVESTON, TEX.

J. F. W——, a vigorous, healthy man, aged twenty-two, while bending forward dragging a gun—muzzle foremost—from under the deck of a boat, received the whole charge in the left clavicular region. About three and one-half to four inches of the central portion of the clavicle and an extensive mass of the adjacent soft tissues were shot away, and the vertebral portion of the first rib comminuted, the charge being lodged between the scapula and the ribs.

Two days thereafter, and as soon as shock was fairly recovered from, assisted by Drs. John M. Haden and Charles Ganahl, I exposed the dorsum scapulæ by a free crucial incision, trephined the bone with a one and one-fourth inch trephine, and removed sixty-four shot, three wads, fragments of clothing, and numerous spiculæ of bone.

Appreciating the importance and also the difficulties of securing union, osseous or ligamentous, of the widely separated fractured ends of the clavicle, I made haste to secure fixation of the parts and give support to the badly drooping shoulder, by means of an angular leathern splint, made to embrace the whole arm, with straps passing front and back, and buckled to a padded leathern shoulder-cap resting over the opposite shoulder.

Aided by skin-grafting the healing of the wound, except the excavation left by the portion of destroyed clavicle, was accomplished in six or seven weeks; but on the removal of the support afforded by the leathern splint, nine weeks after the injury, the shoulder was found to droop in a most disfiguring manner; and, by reason of want of fixation of the shoulder, the movements of the arm were seriously impaired.

A thorough examination revealed *no evidence whatever of any chance for union of the bone, osseous or ligamentous.* I then determined to resort to periosteal grafting. By means of the curved scissors and fuming nitric acid, the new tissue-formation in the tract of the lost bone was removed, and by scraping off the cartilage formed on the ends of the bone an excavation about three-fourths of an inch in depth below the surrounding surfaces, an inch to an inch and one-fourth in width, and measuring two and three-fourths inches between the nearest projections of the ends of the fractured bone was made. To maintain the proper length of the clavicle, a wedge-shaped axillary pad, etc., was applied. Having secured healthy granulations, rendered more vigorous by pencillings with a ten to twenty-grain solution of nitrate of silver, I proceeded to graft the wound with periosteum taken from healthy dogs, chloroformed or killed for the purpose. In case of the animals chloroformed the grafts were obtained from the superficial portions of the long bones of the legs; the scapulæ from the dog killed furnished the best grafts. I found a short, stout resection knife, curved on the edge at the point, best suited for cutting out the grafts, whether of periosteum alone or combined with laminæ of the subjacent bone, using the curved scissors for smoothly completing their separation. The grafts taken were the size of a large flax-seed, and applied with as little delay as practicable. The entire surface of the excavated wound, and the ends of the fractured bone were set with the grafts, placed about three-eighths of an inch apart. After waiting some thirty or forty minutes for the wound to take on the glazed appearance due to the drying of the lymph on its surface, the grafted surface was covered with perforated oil-silk; a compress of picked lint, moistened in two per cent. carbolized water, put on, the whole being held in place by adhesive strips.

On the fifth day, when the dressing was removed, about seven or eight out of every ten grafts of the plant were found to be in process of "taking," rather a better result than with human skin grafts.

The behavior of these periosteal grafts was peculiar. Like the human skin grafts, when applied they promptly adhered like leeches. From the sixth to the tenth or twelfth day—according to the activity of development in the individual graft—the pale red of the periosteal tissue was observed to be giving place to a deeper, brighter red. With the aid of a compound magnifying-glass, minute points of granulations, with their loops of capillaries, could be seen cropping out through and blending with the tissues of the graft. In addition to these developmental changes in the grafts themselves, the surrounding granulations of the wound seemed to take on a marked activity, resulting in a rapid envelopment of the grafts; the granulations of the wound seeming to rise up around and cover in the grafts, ultimately creating little sinus-like openings of communication between the surface of the wound and the grafts in these their sunken nests. After a few days or hours these minute openings closed entirely, leaving only little depressions to mark their site. As soon as the grafts had been thus swallowed up, another grafting of the whole surface was done as before. Three successive plants were made in this manner in the course of a month; cicatrization of the edges of the wound being retarded the meanwhile by cauterization. The excavated wound having at last become fairly filled out with granulations, the surface was skin-grafted with human skin, so as to hasten the healing over, and thus diminish the tendency to contraction of the cicatricial tissues.

Results.—Two months after the periosteum-grafting, examination of the parts revealed the fact that *the two-and-three-fourths inch gap in the clavicle had become filled out* with a tissue possessing the characteristics of bone as to hardness, inflexibility, and perfect performance of the function of giving support to the heretofore drooping shoulder. As felt, beneath the tegumento-cicatricial covering—the result of the skin-grafting—the surface of the new section of bone was nodulated and rough, like a mass of rapidly developed exostosis. It was wanting in the natural contour of the adjacent portions of the clavicle, being more flattened out in its transverse, and more or less distorted in its long axis. There was no appreciable difference in the length of the two clavicles at this time. A careful measurement, made two years later, showed the bone to be one-fourth of an inch shorter than its mate of the opposite side.

[1] Read before the Texas State Medical Association.

And now the question arises, Was this filling up of the gap in the clavicle with *osseous* tissue the result of the periosteum-grafting? Might it not have been accomplished by proliferation of scattered fragments of the periosteum, left *in situ* when the bone was shot away; or the result of developmental extension of the ends of the fractured bone? I am firmly convinced that this formation of bone resulted directly from, and could only have been accomplished by, the periosteal grafting done. I recognize the fact that we are rather prone to argue *post hoc, ergo procter hoc.* It was evident, however, from the extent and peculiar character of the injury to the soft parts that no portions of periosteum could possibly have been left behind; and from quite extensive observations in this class of injuries, in the Confederate Hospitals in Virginia, and in the late Franco-German Army Service, I am convinced that so extensive a loss of bone could not, unaided, have been restored. Besides, nine weeks had elapsed after the injury, and no effort at bone formation could be discovered when the periosteum-grafting was undertaken.

The above case of grafting was done in 1876. I have deferred from year to year its publication, hoping to have opportunities of making further trials in similar cases, but failed to find suitable cases in individuals possessed of enough good sense and freedom from prejudice to submit to obtaining even valuable healing by means of the transference of needed tissues from the lower animals to their own precious bodies. I set up no claim to originality in the extensively cultivated field of "tissue-grafting." Although I fail to find mention, in the literature accessible to me of a similar case, doubtless others have done the same, and possibly with equally good results as in my case.

Since writing the above, I have fortunately had the opportunity of examining J. F. W——, again. As the result of a severe fall, some months since, a simple fracture of the new-formed section of clavicle, with angular union, has occurred. In other respects the bone remains unchanged, except that some contraction in its transverse diameter seems to have taken place since my last examination made about three years ago.

Clinical Department.

THE DRAINAGE OF ULCERS AND SURFACE WOUNDS.

Dr. H. Reder, of Aurora, Ill., writes that, thinking upon the deficiencies of the ordinary methods of drainage and the dressing of wounds, he has been led to devise a new method. He uses a flat piece of sponge, from one-half to one inch in thickness, in the centre of which he cuts a hole corresponding to the outline of the wound, but larger than it, so that the sponge may rest about half an inch from its edges. This piece is then soaked in any antiseptic solution which may be preferred and dried under slight pressure. It is then placed on the surface, the wound occupying the open part in the centre, and over it is put a piece of tinned wire netting with one hundred meshes to the square inch, wrapped in four layers of antiseptic gauze. Over this may be applied the ordinary antiseptic cotton or jute dressing. Dr. Reder says that he has found this dressing very useful in superficial wounds of large or small area in which there was a tendency to burrowing of the pus beneath the surrounding integument. The pressure of the sponge prevents this burrowing, and, the dressing being raised above the surface of the wound, there is no maceration from the retained secretions, and scabbing of the surface is promoted. When skin-grafts are made it is necessary to keep the surface moistened with equal parts of boroglycerine and water, otherwise the rapid drying of the wound may destroy the vitality of the grafts before they have taken root. The same dressing is, however, applicable to deep wounds, the openings of the drainage-tubes being in the open place beneath the wire cover. In the dressing of amputation stumps a cap is made of wire netting which covers the end of the limb. In erosions of the os uteri Dr. Reder employs the same principle. A cap is made to fit over the cervix and to this is attached a cone of wire gauze. Over the cone is drawn a rubber cap, a hole being cut in its centre corresponding to the apex of the wire cone. A cord is also attached to the apex of the cone in order to facilitate its removal by the physician or patient when desired. After making the desired application to the erosions the cap is applied over the cervix. The discharge flows away freely, while the eroded surfaces are protected from all friction, and healing is thus promoted.

POISONING BY CHLOROFORM INTERNALLY ADMINISTERED.

Dr. J. M. Latta, of Millerton, Kan., reports the case of a boy, six years of age, suffering from tapeworm, for whom he ordered a mixture of one part chloroform in three parts simple syrup, of which one teaspoonful was to be given every hour until four doses had been taken. By mistake the parents gave the mixture in tablespoonful doses. Twenty minutes after he had taken the fourth dose of the mixture the boy said the medicine was "about to kill him;" he reeled like a drunken person and vomited violently, throwing up mucus tinged with blood. The child was rational when first seen by Dr. Latta, and said that his stomach hurt him, but in a few minutes he became unconscious. The pupils were normal, the breathing easy, and the pulse a little accelerated but regular, and rather full and bounding. The face was covered with an even red flush, arterial in tint. The temperature was not taken. It was impossible to arouse the boy by calling or shaking him. All the pillows were removed, the body was placed straight and all constricted portions of clothing loosened, and fresh air was freely admitted into the room. The pulse and respiration were carefully watched, but as they furnished no special indications for treatment, nothing more was done. The pulse became gradually less rapid, the flush disappeared from the face, and in an hour and a half the boy awoke and expressed himself as being all right. A saline was administered a few hours later and the bowels were moved, but there was no appearance of any tapeworm.

A CASE OF LABOR WITH PREMATURE RUPTURE OF THE MEMBRANES.

Dr. Ralph M. Cole, of Idaho Springs, Col., relates the case of a married woman, twenty-eight years of age, who sent for him to assist her in her fourth confinement. Her previous labors had been easy and normal. She expected to be confined about the middle of September, but on August 28th the membranes were ruptured spontaneously and about a quart of fluid escaped. From that time until September 8th there was an intermittent flow of the waters, but the patient had no pains or anything resembling pains, though the movements of the child could be distinctly felt. An endeavor was made, after the bag of waters had burst, to bring on labor by the application of hot poultices to the abdomen and the internal use of quinine in doses of three grains thrice daily, but as these measures had no effect the attempt was abandoned. Finally, on September 8th, eleven days after the membranes had broken, labor began and delivery was accomplished with the forceps. The child was alive. Dr. Cole adds that the dose of quinine given may seem very small, but that it is necessary to observe great care in the use of this drug in high altitudes, and even this small amount which his patient took caused headache and ringing in the ears.

THE SERIOUS CONSTITUTIONAL EFFECTS OF ENLARGED TONSILS IN CHILDREN.

Dr. Alfred W. Perry, of San Francisco, Cal., writes in reference to the danger to which children are exposed who suffer from enlarged tonsils. He maintains that it is a mistake to say that the associated symptoms of enlarged tonsils, tumefied lips, pallid complexion, pigeon-breast, and general debility are always due to a pre-existing scrofulous diathesis, but believes that the reverse is usually the case. He claims that hypertrophy of the tonsils is an antecedent and competent, though not an invariable, cause of the *syndrome scrophulosa*, so-called. He writes: "Where much hypertrophy of the tonsils exists, the glands barely meeting in the middle line, the breathing during the day is silent and unembarrassed; but when the child is asleep the palatal muscles are relaxed and the tonsils come in contact. This interferes with the passage of air through the fauces at the beginning of inspiration, and it is not until the aspiratory force of the chest is increased that a little air is drawn through. Then the tonsils meet again, and again separate in consequence of still further expansion of the thorax, allowing a little more air to pass. This is repeated several times, so that each inspiratory act is made up of several jerks. Breathing through the nose is prevented by the associated catarrh and swelling of the nasal mucous membrane. A child who suffers from such an obstruction to free inspiration is in a condition of semi-asphyxia during ten hours out of the twenty-four. Pallor is seen in severe bronchitis of young children, and also in pleurisy with great effusion in adults. An insufficient supply of pure air is considered a potent cause in producing that enfeebled condition which predisposes to phthisis; is not, therefore, a deprivation of pure air sufficient to produce the general debility, stunted growth, and fitful appetite seen in these children? Or, to put it differently, how could an embarrassed respiration during ten or twelve hours of each day fail to produce serious constitutional symptoms? The increased relative pressure on the chest-walls causes a yielding of their framework at its weakest part, the middle of the costal cartilages; this portion is depressed while the sternum and the sternal ends of the cartilages are pushed forward, constituting the deformity of pigeon-breast. This is what happens in young children. But later, when the costal cartilages have become more resistant, this sinking in does not occur, but the ribs assume a more horizontal direction, and the barrel-shaped chest of asthma is produced." Dr. Perry adds that he has been collecting data on this subject for several years, and has now the records of fifteen cases. All the patients had been under his observation for four or five years, or longer, and nearly all were robust children up to the time the tonsils became enlarged. But from that time, with no other sickness than recurrent attacks of tonsillitis, they became pale, thin, listless, had capricious appetite, with frequent attacks of indigestion, and gradually acquired the deformed chest. They were all the children of stout, healthy parents, and ought to have remained so themselves, as they were during the first three to six years of life. And the writer maintains that the hypertrophy of the tonsils must have been the cause of the deterioration of general health. He excludes rachitis as a cause, for the reasons that that disease is very rare in his part of the country, and that it never commences after the first dentition is complete, or in previously healthy children. Of the fifteen cases of which he has records he excised one or both tonsils in eight. In every one of these there was, within a week after the operation, a great improvement in appetite, color, and general spirits; and within a few months the gastric troubles ceased, the children increased in weight, and good health was restored. In those not operated upon no improvement took place. The writer concludes that "the importance of any condition which, on the threshold of life, arrests development and lowers vitality, and produces an evil effect on all later life, cannot be exaggerated. It is worthy of most serious attention, especially as the remedy, excision of the tonsils, is so simple, safe, and speedy in its curative effects."

COCAINE IN GENERAL SURGERY.

Dr. A. G. Browning, of Maysville, Ky., writes that he was called to see a lady suffering from a felon which she had treated by poulticing, pricking, etc., without relief. The integument was abraded, and presented a good surface for endermic medication. A four per cent. solution of cocaine was applied and repeated in ten minutes, after which the finger was incised down to the bone without causing pain. In another case of ingrowing toe-nail, after the subcutaneous injection of ten minims, the nail was slit and a portion removed without complaint on the part of the patient. In a third case, one of earache without inflammatory symptoms, in a boy six years of age, a two per cent. solution was dropped into the external auditory canal, and immediate and permanent relief was obtained. Finally, in a case of organic stricture of the urethra in which there was also a spasmodic element, very marked benefit followed the injection of about ten minims of a four per cent. solution. Dr. Browning adds that he has never witnessed any unpleasant effects which could be attributed to the action of cocaine employed as a local anæsthetic.

OVARIOTOMY PERFORMED DURING AN ATTACK OF ACUTE GENERAL PERITONITIS —RECOVERY.

Dr. William Fox reports the following case: Mrs. H——, aged thirty-eight, was married when very young, and had a child when only sixteen years of age. She began menstruating when twelve years of age and has always been regular, but suffered extremely at each period, more since the birth of her child than before. She became a widow at twenty-five, and remained so for six years, when she married again. Twelve years ago she began to suffer from indigestion and a feeling of discomfort in the lower part of the abdomen, which became somewhat enlarged. The abdomen gradually increased in size, but the patient was never ill until four years ago, when she had an attack of peritonitis, confining her to the bed for two months. After a tedious convalescence, she remained fairly well until June 20th of the present year, when she was again seized with acute general peritonitis. The abdomen had been increasing still more during the past ten months, so that the patient believed herself to be pregnant, and had engaged Dr. J. W. Fisher to attend her. He was summoned on the morning of June 20th, and made a diagnosis of ovarian cyst with acute peritonitis. Dr. Fox was now called in consultation, and three days later Dr. H. Senn was also requested to see the patient. There was at this time great distention of the abdomen, the pulse was rapid and wiry, the temperature ranged from 101° to 103°, the respiration was rapid and entirely thoracic, and intense pain was experienced. Distinct friction could be felt when the hand was applied over the tumor on the right side. After the peritonitis had existed for a week, the woman's condition having grown continually worse, it was determined to operate, this being apparently the only chance of salvation for the patient. At this time stercoraceous vomiting had begun, and death seemed to be inevitable unless something were done at once. A room in the attic of the house was made thoroughly aseptic, and the patient was removed to it for operation. Upon opening the abdomen the evidences of a dry peritonitis, such as has been described by Mr. Tait in these cases, were manifested. The tumor was a monocyst, with a number of small endocysts near the pedicle. It was emptied by means of Emmet's trochar and drawn through the abdominal wound. The pedicle, which was

short and very thick, was divided by the hemostatic forceps into four sections, each of which was separately ligated with silk. The end of the stump was covered with peritoneum, the edges of which were approximated by a continuous catgut suture. No fluid was found in the abdominal cavity. The left ovary was healthy. The wound was closed, after a careful toilet of the peritoneal cavity, with four deep sutures of aseptic braided silk and an equal number of superficial catgut sutures. With a view to guard against engorgement of the large vessels, a bandage of elastic webbing was applied over the Lister dressing. An improvement in the patient's condition was seen immediately after the operation; the respirations were less rapid, and the pulse became slower and of better volume. This improvement could be attributed to nothing but the removal of the excessive intra-abdominal pressure.

Progress of Medical Science.

Pseudo-hypertrophic Paralysis and Thompsen's Disease.—Dr. Vigoureux relates a case in which there was pseudo-hypertrophic paralysis coexisting with the group of symptoms known as Thompsen's disease. There was an exaggerated patellar tendon reflex, and under the stimulus of either the galvanic or faradic current were noted a hardness and rigidity of the muscles, unusual in pseudo-hypertrophic paralysis. The disease in the case reported dated back to early infancy.—*Rivista Clinica e Terapeutica*, July, 1885.

Permanganate of Potash Baths.—Dr. Hüllmann recommends baths in a solution of permanganate of potash in the treatment of the so-called scrofulous exanthemata, in prurigo, eczema, intertrigo, and especially in the period of desquamation of measles, scarlatina, and varicella. The baths should be of the strength of one grain to the pint. The permanganate may first be prepared in concentrated solution in hot water, and afterward added in the proper proportion to the water of the bath.—*Centralblatt für Klinische Medicin*, No. 28, 1885.

Treatment of Dilatation of the Stomach by Electricity.—Dr. Predazzi reports in the *Rivista Clinica e Terapeutica* for July, 1885, two cases of atonic dilatation of the stomach successfully treated by the application of the faradic current to various parts of the abdominal parietes over the enlarged organ. The electricity was applied in this manner for about two minutes each day, and at the end of ten and twelve days respectively a very marked improvement was noted. In addition to the faradic current, the patients were put upon a milk diet and the stomach was washed out each morning with a pint and a half of a 7 per 1,000 solution of bicarbonate of soda.

The Action of Santonine Upon the Liver.—Dr. A. Battistini has been making a number of experiments to determine the physiological action of santonine. He reports that it acts especially upon the liver, increasing the secretion of bile, but causing no alteration in the composition of this secretion.—*Lo Sperimentale.*

Pulmonary Abscess Following Pneumonia.—Drs. Foà and Rattone report in the *Gazzette delle Cliniche Mediche di Torino*, vol. 21, a case of fibrinous pneumonia, complicated with abscess, in which they found two distinct species of micrococci which they were able to cultivate separately. The one was the pneumococcus, the other a very small spherical body which, when injected beneath the skin of a rabbit, gave rise to a cold abscess. In the pus of this abscess, among the anatomical elements, were seen the same minute spherical organisms which had been isolated in the culture. From these observations the writers conclude that pulmonary abscess should not be regarded as a sequela of fibrinous pneumonia, but rather a complication, due to the lodgment in the hepatized lung of a special pyogenic micro-organism.

Cutaneous Eruptions in Cholera.—Dr. A. Montefusco, of Naples, has published a monograph treating of the cutaneous eruptions observed in the different stages of cholera. In the prodromal stage the author noted several forms of eruption, but principally urticaria. This was seen more frequently in women than in men, and particularly in those who had suffered from great mental disturbance—fear of the disease, violent anger, and the like. It was preceded by an intense itching, and it lasted from a few minutes to several hours. Another form observed in the prodromal stage was erythema. It was seen in patches here and there over the face, upper extremities and trunk. The eruption appeared usually simultaneously with the first symptoms of the disease, but was of no prognostic value as regards the mildness or the severity of the attack. In one instance the writer observed in the algid stage a number of small pustules, some diffuse and some confluent, which caused the patient great discomfort, but which disappeared gradually as reaction progressed. It was, however, in the stage of reaction that the greatest variety of eruptions was seen. Most commonly maculæ were noted, of a pale red color, disappearing usually on pressure, and scattered irregularly over the entire body. This eruption faded away on the third or fourth day. Sometimes these maculæ, especially on the extremities, were converted into pustules, and then the eruption disappeared much more slowly. Urticaria was very common and spared no portion of the body, appearing sometimes under the form of maculæ and sometimes as wheals. In two cases the eruption began in the scars resulting from the hypodermic injection of ammonia, and it remained confined to this neighborhood. After urticaria the most frequently observed lesion was acne, which prevailed in individuals of somewhat advanced age, and especially in women. This acne was located chiefly in the limbs, and appeared in the form of small red nodules, painful on pressure, lasting from three to five days. In cases in which the reaction was incomplete and irregular, and in which a typhoid condition supervened, the cutaneous manifestations were very numerous, appearing frequently from the seventh to the ninth day. Besides the forms above mentioned were seen hemorrhagic spots, with or without a previous urticaria, phlyctenoid, erysipelas, erysipelatous zones formed around the points of injection of the ammonia, or eruptions resembling those of measles or scarlatina. The eruption of measles was seen during the period of susidence of the epidemic and was manifested chiefly in young girls or female infants. In two cases a scarlatiniform eruption was noted, and in one it was associated with petechiæ. In some individuals there was an eruption of papules, passing into pustules, and ending with the formation of large crusts which persisted for a long time. As to the prognostic value of the cutaneous eruptions, Dr. Montefusco observed that the patient usually recovered when the eruption appeared in the prodromal stage or in normal reaction, but that when it was hemorrhagic or when it made its appearance in a stage of incomplete or typhoid reaction, the result was invariably fatal. In the morbillous eruption the prognosis was favorable.—*Lo Sperimentale*, No. 6, 1885.

Growth of Teeth in a Fœtus.—Dr. Weddize reports in the *Allgemeine Medicinische Central-Zeitung*, No. 55, 1885, a case of labor in which he was called to assist the midwife on account of some complication. Delivery was finally accomplished, and while the child was being bathed it was found that it had the two lower incisor teeth almost through the gums. The mother said that she had given birth six years before to a girl in whom the two lower incisors were already in sight. In this child the two teeth which had made their appearance so early in life fell out at the end of two years.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, October 3, 1885.

THE CHANCES OF AN INTERNATIONAL MEDICAL CONGRESS IN AMERICA.

IT is evident that the work done by the Committee of the International Congress at its secret meeting in this city is an utter failure. The Committee has won over no new friends, but, on the other hand, withdrawals continue to be made. We believe that there is no exaggeration in saying that there are not half a dozen representative men in the profession now who are prominently connected with the organization of the Congress.

The attempt to hold an international meeting under such circumstances seems certainly very wrong, while, if affairs continue on as at present, there will be a collapse of the whole affair before the year 1887. It is known that some of the gentlemen who withdrew from the Congress did so partly because they found that they could not get co-operation at home or abroad; they could not organize sections so as to secure successful work; and this difficulty must steadily increase.

Beyond all this, the obstinate conduct of the gentlemen who are trying to arrange the Congress on American Medical Association principles is arousing a constantly stronger indignation among the profession at large. It is clearly seen that their perversity and disloyalty are bringing discredit upon American medicine.

Since there are no hopes of a genuine International Congress under the present management of affairs, the question arises as to what is the best course to pursue. Either the profession must take hold of the matter and reorganize anew, or we must beg our European brethren to withdraw their invitation. We should greatly regret to be forced to the latter alternative, especially as American physicians are very earnestly desirous of having the International Congress held here.

This being so, it only remains that they strive to act harmoniously and energetically with a view, at the next meeting of the American Medical Association, of reconsidering the hasty and ill-considered action taken at New Orleans. It will only be necessary, after all, that at the session in St. Louis, next spring, the policy of the original Committee be adopted, and that of the present Committee rejected. A large part of the detail work needs no change. Such restorative action might be criticised as inconsistent, but the injury of such criticism would be small indeed compared with that wrought by a pursuance of present methods. For it cannot be too often or too emphatically reiterated that a Congress like the one now being foisted upon us, a Congress that has been inoculated with the poison of a foreign and disorganizing issue, will be practically a failure. The removal of this issue, even so late as next spring, would still give time for organization to be effected. While there is yet this possibility of some change being effected at St. Louis, we will not quite give up the Congress. But meanwhile it will be hardly necessary to say that those who wish well of their profession will carefully keep aloof from all connection with the present Committee on Organization, which might better be called a Committee on Disorganization. This Committee should be vigorously let alone.

FERRAN'S STATISTICS OF CHOLERA INOCULATION.

WE have received a small pamphlet purporting to be the first series of statistics concerning the effects of the so-called preventive inoculation of Asiatic cholera. It contains reports from seven towns in Spain in which the cholera was prevalent during the past summer, and covers a period of about three months from the middle of May to August 10th. The reports are certified to by the local physicians, the alcade, or mayor, and, in most cases, also by the municipal judge and the parish priest, and have, furthermore, a notarial certification. They would seem, therefore, to be both official and authentic, and are undoubtedly as nearly correct as statistics gathered in times of panic and general distress can be. The seven towns are Alberique, Alcira, Benifayó, Cattaroja, Cheste, Chiva, and Masanasa, with an aggregate population of 41,641. The tables give the number of invasions and of deaths among the inoculated, the re-inoculated and the uninoculated. The statistics of the re-inoculated, however, are not complete, as the decree making it illegal for anyone but Ferrán himself to practise the experiment rendered it impossible in most cases to inoculate the second time. It will be remembered that Ferrán asserts that the second or "massive" inoculation will assure certain immunity to the subject. But from the few figures presented it would seem that this claim is not borne out by facts, for in Alcira there were 55 invasions, with 9 deaths among the 8,830 individuals who were reinoculated.

But it is in the effects of primary inoculation that we are chiefly interested, for if every inhabitant of a city like New York must be inoculated twice before he is protected from cholera, the epidemic would wear itself out or be killed by frost before the physicians would have finished their work. In the tables before us we find that out of a total of 41,641 inhabitants, 20,382 were inoculated by Ferrán or his assistants, leaving 21,259 who could not or would not avail themselves of the protection offered them. Of the latter number, 1,584 (or 7.45 per cent.) were attacked by the disease, and of these 824 (or 52.02 per cent.) died. Of the 20,382 inoculated, only 232 (or 1.13 per cent.) were attacked, and of these 75 (or 32.33 per cent.) died. These figures do certainly seem to point strongly to the efficacy of inoculation as a preservative measure, especially when we consider that the experiment is a new one, and Ferrán cannot be supposed to have been as skilful in his early operations as he might claim to be after having had more experience; and, furthermore, it might reasonably be asserted that

when inoculations were practised in such a wholesale way (as in Alberique, for instance, where 594 of the inhabitants were inoculated in one day), many would fail to "take," and then, if one of these individuals acquired cholera, a mark would be scored against the method.

But there are other points to be taken into consideration. Fear, as is well known, is a potent factor in predisposing to cholera, and the feeling of security resulting from having undergone the operation may have conduced to the immunity enjoyed by the inoculated. Again, the statistics before us embrace only seven small towns, in none of which, Alcira excepted, was there a population of six thousand souls, and it may be that the reports from other places will be less favorable. As Ferrán, in his preface to the pamphlet, truly says, if it were a question of the efficacy of some new remedy these figures would be accepted without hesitation, and physicians the world over would at once adopt the method of treatment in their practice with every confidence of success. But the weight of evidence needed to establish any theory as a fact varies greatly according to the antecedent probability or improbability of the theory. Now the theory of preventive inoculation of cholera is antecedently improbable and is so regarded by nearly every scientific man whose opinion carries weight and who has studied the subject at all, and the testimony in its favor must, therefore, be overwhelming in order to be convincing. We do not think that Ferrán has yet proved his theory to be a fact. We wish he had, but he hasn't, and we fear he must produce stronger figures than these before he can obtain the coveted prize which awaits the discoverer of a means of preventing cholera.

SOME SIMPLE HISTORICAL STATEMENTS.

For copiousness of statement and fertility in explanation our esteemed contemporary, the *Journal of the American Medical Association*, has, we believe, no historical parallel.

In its issue of the 26th ult., the whole story of the organization of the Ninth International Congress is retold, with the express assurance that this is the only truthful and historical account. We regret to find, however, that our official contemporary, while stating in an agreeable manner what every one knows, is absolutely incorrect in representing the spirit of the present issue.

We are told, for example, that at the meeting of the Association in New Orleans, the report of the original committee "was freely criticized, several members pointing out the fact that . . . it had given undue prominence to a particular portion of the profession which was well known to have arrayed itself in opposition to the State and National organizations."

The "historical facts" here are that the members in question said nothing about "undue prominence," but urged that the particular portion of the profession referred to should receive no recognition at all, but, in fact, that it should "be taken by the top of the head and its throat cut at once." It is unfortunate that our contemporary forgot about this bit of medical Burchardism. It is bound to be an essential part of history.

Our contemporary, continuing its simple historical recital states that the resolutions then adopted, appointing an enlarged committee, "contain not one word about the Code of Ethics, . . . and prescribe no rule either for the membership, government, or officering of the Congress." Apart from the fact that the foregoing sentence is not very good English, we can find no fault with it as "a historical statement." But unfortunately it has only a technical and historical value. It is very well known that the new committee was expected to ignore all persons of New Code affiliations. If not, why was it that the chairman elected for this new committee, Dr. Cole, was a gentleman who said distinctly, in discussing the Keller resolution, that "he would place none in official positions who were not recognized as loyal to the Code of Ethics."

Our contemporary is to the last degree disingenuous. It knows very well that the New Orleans committee was expected to leave out of the Congress all New Code or no Code men. They did this at the meeting in Chicago. They were forced by public opinion to yield a little at their subsequent secret conference in New York. If the New Orleans resolutions were passed with the intention of still leaving out the Code issue, why does not the present committee recognize the fact? If the Association meant not to have an ethical issue brought in, as our contemporary would have it inferred, then the Committee has been stupidly, criminally wrong in introducing it. Let us have a simple historical statement regarding this committee, and as to the authority by which it excludes a large number of eminent men from the organization of the Congress. This would fitly complete the diuresis of explanations and "simple historical statements" which our Chicago contemporary has been making.

News of the Week.

A Quarrel among the German Physicians.—The appointment by Prince Bismarck of Dr. Schweninger as professor in the Berlin University, has ended in producing a very lively quarrel in the medical world of Germany. It seems that last February, when the question of voting Schweninger his salary came before the Lantag, Dr. Graff, presumably at the dictation of Bismarck, supported the motion for the salary. In speaking in favor of Schweninger, he seems to have used very little tact, and even to have ventured to cite the case of the appointment of Virchow as a precedent. The comparison of Schweninger to Virchow has roused the deepest indignation among the Berlin physicians. Although, like most Germans, not gifted with a great amount of civic courage, they have entered upon a vigorous warfare against Dr. Graff. This gentleman has for several years been President of the "Deutscher Aerztevereinbunde," a position of considerable political importance. The fight is now to prevent his re-election.

The Cholera.—The number of new cases of cholera in Spain is steadily decreasing. The ratio of mortality is also less than at first. Cholera holds its own still in certain parts of Italy. In Palermo, for example, there were 162 new cases reported on September 28th. In Spain the daily number of new cases is about 500.

Why the French Canadians in Montreal refuse to be Vaccinated.—Dr. L. D. Mignault, of Montreal, Canada, sends us the following: "In reading this morning your article entitled 'The Montreal Epidemic, and the Utility of Vaccination,' I was struck by a statement therein, to which as a Montrealer and a French Canadian, I must take exception. You say: 'It appears that the Canadian Catholics, on religious grounds, do not allow themselves to be vaccinated.' The answer to this lies in the fact that not only has vaccination been recommended by an episcopal circular from the Bishop of Montreal, but moreover, nearly every religious community in town has been revaccinated within the past month. At the same time many such communities have forced all their servants to be revaccinated under pain of instant dismissal. You may see by this that objections to vaccination do not rest upon religious grounds, but, as I will explain, have an entirely different origin. In the first place, for several years medical men, whose experience and ability have gained for them public respect and confidence, have unhappily been pleased to flood the press with articles denouncing vaccination, and representing it as the source of many evils, not excluding small-pox itself. At the same time ward politicians and others have from time to time denounced in thrilling terms the horrors of vaccination, aiding their oratorical efforts with vividly colored plates. Secondly, a few cases of erysipelas and other accidents bore out to a certain extent some of these statements, and thus the public mind became biassed against vaccination. The French Canadian, like all representatives of the Latin races, is of a thoroughly inflammable nature, and subject to strong prejudices. With time, patience, and reasoning vaccination will certainly come again into universal favor in our city, and already many of its strongest opponents have become entirely reconciled to it."

Cholera on a Vessel Bound for New York.—An Italian bark, hailing from Marseilles, arrived at this port last Saturday, and reported that one case of cholera had appeared on board three days after the vessel started. The patient died in twenty-four hours, and no further case developed. Great care has been taken by our health officers to see that the vessel was properly disinfected and quarantined. No trouble can possibly be expected from it at this date.

The Small-pox in Montreal.—It is estimated by some that there are between 3,000 and 4,000 cases of small-pox in Montreal. The Health Board, however, reported only 48 deaths from this disease on September 28th.

A Casualty Column for Physicians will, we fear, have to be opened if the returns of homicide, suicide, etc., continue as at present. On September 28th, the papers report that Dr. G. W. Barton, of Bloomington, Ill., was shot and killed by Dr. H. L. Harris, of the same town. It seems that the quarrel arose indirectly out of Dr. Harris's coming to Bloomington and cutting into the practice of Dr. Barton. This latter gentleman resented it and made some harsh criticisms upon his confrère which gave occasion for the quarrel. Perhaps one of the minor morals to be drawn from the unhappy event is that the medical profession is very much over-crowded. It is not very unnatural that, when a new man enters a town and proceeds to take away some of the practice of the older physician, there should be hard feelings. Both claim that they must live, and no doubt the claim is somewhat reasonable.

Changes in Hospital Districts.—A new emergency hospital has been or is soon to be opened at Gouverneur Slip. This hospital will receive cases from the Seventh, Tenth, and Thirteenth Precincts. Another emergency hospital is to be opened on the East River front, between One Hundred and Eighteenth and One Hundred and Twenty-fifth Streets. It is stated that there is some feeling manifested about a proposed arrangement to give the New York Hospital the Twentieth Precinct, which will leave the Roosevelt Hospital with but one precinct, the Twenty-second. Such a system would give the New York Hospital an immense territory, so that a compromise has been suggested by which the Roosevelt Hospital is to have one-half of the Thirty-first Precinct—the territory included by Forty-second and Eightieth Streets, Sixth and Eighth Avenues and the North River.

An Anti-vaccination Riot in Montreal.—The by-law passed by the Provincial Board of Health, making vaccination compulsory, having appeared in the *Official Gazette*, increased the excitement among the French Canadians in Montreal to such an extent that a riot broke out in the east end Tuesday morning, and before the crowd dispersed they smashed many of the windows of the East End Health Office. The riot continued the next night and considerable damage was done. Of course, an obstinate prejudice among the ignorant, fostered by fanatics and a few so-called physicians, was the exciting cause of the riot. But no doubt race feeling had something to do with it. Medical opinion is practically unanimous on the subject of the utility of vaccination, and it is idle to discuss its claims.

Civil Service at the Hospitals.—That wonderful adaptability of questions to candidates sometimes seen in civil service examinations, has at last appeared at the hospitals. At a recent examination in this city, one of the candidates was asked among others, the following questions under the head of "Practice." "Give the highest specific gravity of the blood ever known in diabetes?" "In what country do you find the most tapeworms?" "Number of ova laid by one segment of a tapeworm?" "In what part of the intestine do you find the most cystocerci?" We think the examiner might have profitably added one or two more. "If a man has a tapeworm, and takes an anthelmintic, how much of the worm will he pass at the first sitting?" "Will the worm like being passed?" and "If the worm does not like being passed, what is he going to do about it?"

Dr. Thomas MacIntire, for twenty-five years Superintendent of the Indiana Institution for the Education of Deaf-Mutes, but more lately of the Pittsburg institution, died on Friday of last week, after a protracted illness, in the seventieth year of his age. He was one of the best known deaf-mute instructors in the country.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, September 28, 1885.

DANIEL LEWIS, M.D., PRESIDENT, IN THE CHAIR.

DR. A. F. CURRIER read a paper on

GONORRHŒA IN THE FEMALE,

in which he first presented the argument in favor of its being an infectious disease, due to a micro-organism, or gonococcus.

In most cases it was limited by the os internum ; less frequently it invaded the urethra and bladder ; extension of the process through the Fallopian tubes to the peritoneum was possible, and this fact had been known for many years. Gradually the profession was approaching the acceptation of the views announced by Dr. Noeggerath in 1872, who directed attention to a particular form of the disease, namely, that which involves the Fallopian tubes, and in addition to simple catarrh and hydro-salpinx there are other more serious conditions, usually of an infectious nature, either tubercular, syphilitic, or gonorrhœal. The gonorrhœal form most frequently goes with pyo-salpinx, but the latter was not necessarily of gonorrhœal origin. The diagnosis rests upon the discovery of the gonococcus.

With regard to prophylaxis, Dr. Currier believed that any class of persons who were liable to distribute infectious disease should be under properly regulated medical police regulations.

Marriage should not occur as long as gonococci could be found in the discharges.

According to Oppenheimer, corrosive sublimate, creasote, and nitrate of silver are the only germicides which destroy the cultivated microbes.

Other remedies, however, had been used clinically with success, and that which had given Dr. Currier the best results was a combination of nitrate of bismuth and glycerine ; he had not obtained satisfactory results with a sublimate solution. Bismuth one drachm, glycerine one ounce, applied upon a cotton tampon, which was allowed to remain ten or twelve hours, then removed and the vagina washed with hot-water injections. Perhaps the mixture was not directly destructive, but its action deprived the microbes of the material necessary for their propagation and they died of starvation.

Dr. Noeggerath had said that it could not be cured, but Dr. Currier believed that if the case was treated sufficiently thoroughly and for a sufficient length of time, the disease could be cured ; that is, the micro-organisms could be killed.

DR. H. T. HANKS said it was still a mooted point whether or not the disease was produced by a specific germ ; but the results and the method of treatment were well known and generally accepted. He believed that a very large percentage of the diseases peculiar to women were due directly to gonorrhoea. He regarded it, however, as practically impossible to make a diagnosis in most of the women in well-kept houses, because of their habits of cleanliness. But the results were practical, and the question was, what could be done to prevent the suffering entailed by the disease. He thought all should go to work with more confidence than had usually been expressed that the affection could be cured. Patients should be treated every *third* day, except for about eight days, including the period of menstruation. His favorite plan had been to *distend* the vagina from four to six times a day with a solution consisting of chlorate of potash, two drachms, and hot water, one quart. When this was carried out thoroughly, so that every portion of mucous membrane was washed with the solution, the disease would be generally stopped quickly. It was most essential that frequent and copious warm-water douches be made, keeping the parts absolutely clean, every three or four hours ; the medication of the solution —whether it be carbolic acid (ʒ j. to O ij.), chlorate of potash (ʒ ij. to O ij.), or corrosive chloride of mercury (gr. ij. to O ij.)—was of less importance, either will cure when used frequently and in copious quantities.

DR. GARRIGUES had not looked for the gonococcus, but had diagnosticated his cases by the virulence of the inflammation. He had found that the glands of Bartholini were very liable to be affected, and that then the case proved obstinate. His method then was to lay the abscesses open and wash with a sublimate solution 1 to 2,000. According to his observation the disease does not, as a rule, attack the urethra, as was formerly taught. In the treatment of the chronic conditions glycerine, with or without medication, worked very well.

DR. BOLDT thought the urethra was not affected so infrequently as perhaps might be inferred from the paper and the remarks made during the discussion. His treatment had consisted in the use of equal parts of glycerine and a saturated solution of boracic acid, together with injections of boracic acid, half an ounce to a gallon of water. In the majority of cases, it would be well toward three months before cure could be effected.

DR. H. G. LYTTLE said that, when House Surgeon in Charity Hospital, the practice was to apply plain glycerine upon a tampon, confine the patients to the bed, and that they got well in two weeks, as a rule.

DR. MESSENGER said that the injections should be given by the physician, as no woman could properly syringe herself. The vagina must be thoroughly distended, and the bichloride solution was the best remedy he had used.

DR. CURRIER said, in closing the discussion, that the urethra was not apt to be involved in the majority of cases, and that the anatomy of the parts favored this immunity. Again, symptoms of supposed urethritis were, perhaps, frequently simple inflammation of the peri-urethral glands, which open upon the floor of the urethra. He thought it quite probable that the glycerine, in all the mixtures named, played an important part, but he was also certain that bismuth was a valuable remedy ; he was also quite sure that the two remedies were improved by being mixed with each other.

DR. GEORGE HENRY FOX, then read a paper entitled

REMARKS ON THE TREATMENT OF LEPROSY.

Cure of this disease was rarely hoped for by either physician or patient. But he thought it should not be regarded as necessarily an incurable affection. The point to which he wished to direct special attention was the *morale*, the *mental condition of the patient.* To inspire hope and confidence was a most important point in the treatment of leprosy. The full belief, on the part of the patient, that leprosy is an incurable disease, he believed, counteracted the effect of medical treatment. It is a contagious disease. It is quite probably transmitted by hereditary influences. Aside from inheritance, leprosy is only communicable by inoculation of the blood with the morbid secretions of an affected person. Compulsory segregation is undoubtedly judicious. The chaulmoogra oil is probably the remedy which has afforded the best results.

DR. F. C. FULLER had seen a large number of cases of leprosy in the West Indies, where but little restraint was placed on their movements, and where also its contagiousness was quite well established.

DR. J. A. MOORE had also seen a large number of lepers in the West Indies, and thought that the buoyancy of their feelings was most remarkable. As he had observed it, the disease seemed to progress to a certain point and then become stationary. With regard to heredity it was very apt to skip an entire generation, and then not reappear in all the members of a family.

DR. J. C. PETERS had seen the lepers in Havana, and

while they lived like dogs, they seemed to be perfectly happy and indifferent as to their condition.

Dr. D. Bryson Delavan had seen a large number of lepers with Professor Hansen, of Norway, where the disease was regarded as hopeless so far as cure was concerned, yet the care which these people received was far superior to that given them in any other country. Comparative isolation had been advantageous, and had reduced the number from three thousand to scarcely seventeen hundred, and the government hoped to eradicate the disease entirely, although the chronicity of the affection was such that twenty years had already been spent in that direction. It was usually found among the lowest classes, yet the disease occasionally appeared in other places. In the way of treatment very little was done, except to endeavor to alleviate the more distressing symptoms. It was well known that Prof. Hansen was the discoverer of the bacillus lepra and was an acknowledged authority on this subject in Europe. The hospitals for these patients were in good condition, but it was through isolation that the best results, so far as eradicating the disease was concerned, were expected.

Dr. Piffard had never known it to spread among the good classes, whereas among the lower classes it certainly did spread. Where there is a good deal of the disease, treatment amounts to nothing. During the last ten years he had had under his observation probably *thirty* cases, and of these only *two* died, and every case improved under the systematic and persistent use of chaulmoogra oil and strychnia with natural combinations, chiefly, as hoang-nan. He had been unable to keep up the use of these remedies very long at any one time, and had, therefore, given one as long as it was possibe to get the patient to take it, and then substituted the other and continued it in the same way. He had not seen a case cured, but had seen patients benefited to an extent which permitted them to return to lives of usefulness. He believed that there were some fears of contagion.

The Society then adjourned.

THE MEDICAL SOCIETY OF VIRGINIA.

Sixteenth Annual Meeting, held at Alleghany Springs, Montgomery County, Va., September 15, 16, and 17, 1885.

Tuesday, September 15th — First Day — Evening Session.

The Society was called to order at 8 P.M. by Dr. Bedford Brown, a railroad accident having prevented the President, Dr. S. K. Jackson, from arriving in time. About one hundred and fifty members were present.

DELEGATES FROM OTHER SOCIETIES.

Drs. Archer Atkinson, of Baltimore, and J. S. Conrad, of Matley Hill Sanitarium, were present as delegates from the Medico-Chirurgical Society of Maryland, and Dr. Thomas R. Evans from the Medical Society of West Virginia. Dr. George T. Harrison, of New York, Honorary Fellow, and Dr. William G. Eggleston, of Chicago, a member of the Society, were also present. Over one hundred new members were received into the Society.

Dr. H. M. Clarkson, of Haymarket, delivered the

ANNUAL ADDRESS TO THE PUBLIC AND PROFESSION,

before an audience of some four hundred ladies and gentlemen in addition to the members. The address dealt chiefly with the question of medical societies and of their relation to the public.

Dr. Isaac White, of Alleghany Springs, read a paper on the

MEDICAL PROPERTIES OF THE ALLEGHANY WATERS.

The temperature of the springs is 56° F., and the waters contain baryta, strontia, and magnesium salts. Owing to the presence of the two former ingredients the waters are somewhat similar in their effects to those containing arsenic. The speaker did not regard the waters as a "cure all," but was convinced of their great value in the treatment of dyspeptic disorders. The dose was one glassful, gradually increased to two, before meals, varying however as it was desired to secure tonic, diuretic, or cathartic action. When first taken, the waters sometimes caused a feeling of giddiness or even headache, and might cause erythema, eczema, or an eruption of furuncles.

Dr. William C. Dabney, of Charlottesville, in his capacity as President of the Board, read the

REPORT OF THE VIRGINIA STATE BOARD OF MEDICAL EXAMINERS,

showing that since the beginning of the year, thirty-two candidates had passed satisfactory examinations and had been licensed to practise medicine in the State, while six had been rejected. All of the candidates were college graduates.

Wednesday, September 16th—Second Day—Morning Session.

Dr. S. K. Jackson, of Norfolk, delivered the

PRESIDENT'S ADDRESS.

The speaker said that he regarded his elevation to the highest office in the gift of the profession of Virginia as an expression of appreciation of his endeavor to interest the Society in the question of zymotic diseases, especially as regards prophylaxis. He first considered the impediments in the way of rapid progress of medical science, then dwelt upon the factors favoring its recent high development, and finally discussed the measures which seemed most efficacious in ensuring its continued growth.

Dr. Thomas J. Moore, of Richmond, opened the subject for general discussion by reading a paper on

SCARLET FEVER,

accepting the classification of the disease, usually adopted by American writers, into scarlatina simplex, anginosa, and maligna, and describing very minutely the classical types of each of these forms. Then, after tracing the history of the disease from its first definite description by Sydenham, the speaker dwelt upon its etiology, and also discussed the germ theory of disease. He was not prepared to accept either the *Monas scarlatinosum* of Klebs, or the *Plox scindens* of Eklund, as the bacillus of scarlet fever, and did not believe that the specific microbe had yet been discovered. On the subject of treatment, the author rejected belladonna as useless in prophylaxis and of very little value in palliating the symptoms. For the reduction of temperature he preferred the external application of cold by means of an ice-bag to the head, the wet pack, or, as a last resort, the cold bath. His favorite internal antipyretic had been quinine, but he hoped much from resorcin, and urged his hearers to test its efficacy as opportunity offered. Externally he used a mixture of carbolic acid, ♏ xv.; borax, ʒ j., and glycerine, ʒ j., and was pleased with its action. In the dropsy of acute desquamative nephritis he recommended the exhibition of small doses of mercury for a few days when the ordinary diuretics were not accomplishing the desired end.

Afternoon Session.

This session was devoted to the

ELECTION OF OFFICERS.

for the ensuing year. The following were elected:

President—Dr. Rawley W. Martin, of Chatham.

Vice-Presidents—Drs. John S. Apperson, of Town House; T. B. Greer, of Rocky Mount, and H. M. D. Martin, of Fredericksburg.

Recording Secretary—Dr. Landon B. Edwards, of Richmond.

Corresponding Secretary.—Dr. J. F. Winn, of Richmond.

Treasurer—Dr. R. T. Styll, of Richmond.

Dr. Hugh T. Nelson, of Charlottesville, was appointed to deliver the annual address to the public and profession in 1886, and Dr. L. Ashton, of Falmouth, to lead in the discussion on "Puerperal Septicæmia" at the next meeting.

Drs. Thomas J. Moore, and Hugh M. Taylor, of Richmond, and Meade C. Kemper, of Norfolk, were appointed Examiners on the State Board.

It was voted that the

SEVENTEENTH ANNUAL MEETING

be held in Fredericksburg, during November, 1886.

EVENING SESSION.

DR. BEDFORD BROWN, of Alexandria, presented a paper in continuation of the

DISCUSSION ON SCARLET FEVER.

The speaker dwelt chiefly upon the therapeutics of the disease. He made frequent use in his practice of a formula containing salicylic acid, tincture of aconite, ammonia, and digitalis, and found that it diminished fever more decidedly than any other antipyretic he had ever employed, and acted also as a diaphoretic and diuretic. He deprecated the giving of frequent baths as being too exhausting in adynamic cases. In renal dropsy with engorged kidneys, a full dose of calomel, followed by jalap, would often do good, but when there is a cool skin with pallor, feeble pulse, and great prostration, purgatives are not well borne. Lumbar poultices, digitalis, acetate of potash, and occasional saline laxatives may then be used.

DR. R. J. HICKS, of Casanova, had never, in his thirty years' experience, seen anything indicating a

RELATIONSHIP BETWEEN SCARLATINA AND DIPHTHERIA,

nor had he ever seen scarlatinal throat complications threaten life. He believed strongly in the necessity of an abundance of fresh air in the management of a case of scarlet fever, and said that malignancy was dependent upon bad sanitation, for zymotic germs do not live in pure air but are bred in filth.

DR. ALEXANDER HARRIS, of Jeffersonton, dwelt especially upon the necessity of perfect ventilation and thorough cleanliness. He thought that boiling water or steam was better than the disinfectants in popular use for cleansing the clothes of the patient, or the room in which he has been sick.

DR. C. T. LEWIS, of Clifton Forge, believed in the stimulating plan of treatment, and also in the giving of a liberal supply of nourishing food.

DR. J. T. WINN, of Richmond, agreed with the speakers in their advocacy of sanitary measures. Chloride of lime or corrosive sublimate were the best substances to use in the disinfection of linen and other articles which could not be burned.

DR. L. LANKFORD, of Bowers, thought that malignant scarlet fever would be rarely seen if the importance of pure air were more generally appreciated.

DR. J. HERBERT CLAIBORNE, of Petersburg, related several instances in which individuals had acquired the disease in a mild form after having come in contact with very severe cases, and *vice versa*.

DR. WILLIAM L. ROBINSON, of Danville, was a believer in the efficacy of medicinal treatment. He used baths to reduce the temperature, and allowed his patients to drink freely of lithia water during the course of the disease.

DR. W. W. PARKER, of Richmond, advocated the free use of alcohol in malignant cases, and believed he had saved many cases since adopting this plan.

DR. M. A. WILSON, of New River Depôt, had seen good results from the use of belladonna in throat complications.

DR. HUGH T. NELSON, of Charlottesville, insisted upon the necessity of isolation, even of the mildest cases, in order to prevent the spread of the disease.

THE CHLORINE TREATMENT

of Watson, as described in his work on the "Practice of Physic," was advocated by Drs. Jackson, Thomas, Lewis, Broaddus, Grammer, and Cooper.

DR. M. G. ELBEY, of Washington, D. C., presented a

REPORT ON CHEMISTRY, MATERIA MEDICA, AND THERAPEUTICS,

reviewing the progress made in these branches during the past year.

DR. S. W. DICKINSON, of Marion, followed with the

REPORT ON OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN,

dwelling especially upon antiseptic midwifery, anæsthesia in labor, neurasthenia, the treatment of uterine displacements, and the therapy of children's diseases.

THURSDAY, SEPTEMBER 17TH—THIRD DAY—MORNING SESSION.

DR. R. T. STYLL, of Richmond, presented the

TREASURER'S REPORT,

showing a balance, after the payment of all expenses to date, of $390.55.

DR. W. D. TURNER, of Fergusson's Wharf, in behalf of the Committee appointed to consider the subject, reported in favor of a petition for the enactment of

A LAW TO REGULATE THE PRACTICE OF PHARMACY.

DR. BEDFORD BROWN, of Alexandria, then read a paper on the

TREATMENT OF LACERATIONS OF THE OS AND CERVIX UTERI WITHOUT SURGICAL OPERATION.

While admitting the advantages of Emmet's operation as a prompt means of relief, though not unattended with danger, there were yet many females, the author said, who were debarred from these benefits and for whom some other method, or none at all must be used. During the past twelve years the writer had treated successfully upward of twenty cases of laceration and fissure of the os and cervix, of varying degrees of severity and some complicated with cellulitis, displacements, subinvolution, etc., by means of local applications alone. The patients suffered from severe neuralgic pains, and in most of them there was more or less impairment of the general health. The writer had seen several cases of laceration in the acute stage heal by first intention after the enforcement of absolute rest and the carrying out of measures of strict cleanliness and disinfection. Warm douches containing borax, boracic acid, and carbolic acid were used gently two or three times a day. If the lacerations did not heal within two weeks they would not heal at all by first intention. In the treatment of old lesions the author had obtained the best results with graduated solutions of nitrate of silver. He applied a solution of thirty grains to the ounce freely to the interior of the cervical canal, and another of fifty grains to the ounce was painted over the whole external surface of the os and cervix until a uniform thick white coating was formed. This coating protects the exposed nerve-filaments, allays inflammation, stimulates the growth of healthy granulations and prevents the absorption of septic matters from the discharges. The solution should be made to penetrate to the very bottom of the fissure in order to ensure success. If hypertrophy and induration of the cervix remain after the lacerations are healed, an application to the external surface is made of a solution of nitrate of silver, ʒ ij. to ℥ j. Several of the patients thus treated became pregnant, whereas while the disease existed they were sterile, and being examined after the birth of their children, the cervix and os were found in every case to be normal and entirely free from disease.

Dr. George T. Harrison, of New York, followed with a paper on

PUERPERAL SEPTICÆMIA,

referring especially to its prophylaxis and treatment. The disease, he said, is one that comes from without and cannot gain admittance unless a wound exist somewhere along the genital tract. But the inner surface of the uterus is one large wound, and there are almost always rents in the cervix, vagina, or vulva. In puerperal fever the carriers of infection are either the pathogenous fungi, which generate traumatic diphtheria, pyæmia, and septicæmia, or they are putrefactive germs. The latter are ubiquitous; the former are imported by the hands, instruments, etc. The former affect the organism immediately; the latter indirectly, by their influence on decomposable matters. The principles of prophylaxis consist in pure air for the lying-in-woman, thorough disinfection of the genital tract, and the observance of strict surgical cleanliness on the part of the accoucheur. During pregnancy the woman should frequently wash the external genitals with soap and water, and afterward with a boracic-acid solution. The speaker deprecated the use of antiseptic vaginal injections during labor, unless the patient had been exposed to the possibility of infection, or in tedious and complicated labors during which frequent examinations had to be made or instruments used. All lacerations of the perineum should be closed under strict antiseptic precautions, and iodoform should be dusted over the raw surfaces.

Dr. H. Grey Latham, of Lynchburg, presented the

REPORT ON ADVANCES IN SURGERY,

and Dr. Rives Tatum, of Harrisonburg, the

REPORT ON ADVANCES IN THE PRACTICE OF MEDICINE.

Dr. R. C. Powell, of Alexandria, read a paper entitled

CLINICAL NOTES ON CARCINOMATOUS AFFECTIONS OF THE DIGESTIVE ORGANS,

in which he dwelt especially upon the unreliability of gastric symptoms as evidences of gastric affections, and upon the great value of cachexia as corroborative evidence of malignant disease. He regarded cachexia as a more certain sign of cancer than even the presence of a tumor. There is no specific for the cure of carcinoma, and the treatment might be briefly stated to be the permission of "amusement without excitement, exercise without fatigue, and nutrition without stimulation." The diet should be regulated so as to compensate for the impairment of the digestive function of the organ involved, whether that be the stomach, the pancreas, or the liver.

Dr. M. A. Rust, of Richmond, followed with an exhaustive and interesting paper on

THE ETIOLOGY OF ZYMOTIC DISEASES.

The credit of paving the way for the evolution of the germ theory of disease was due, the writer said, to the botanists and biologists, who, in studying certain epidemic diseases among plants and insects, found that they were always due to the action of some low form of life. Then it was that medical men began to suspect that a similar cause lay at the foundation of the zymotic diseases in higher organisms. The writer then mentioned the different varieties of microbes, and discussed the various theories concerning their origin, their mode of action within the tissues, and the way in which they are finally overcome and eliminated from the organism.

Dr. M. L. James, of Richmond, then read a paper on

DYSPEPSIA AND NEURASTHENIA,

in which he traced the dependence of these two conditions one upon the other, and the evil effects which they mutually exert upon each other, and offered suggestions for the treatment of these distressing affections.

AFTERNOON SESSION.

At this session, when the

REPORT ON ADVANCES IN HYGIENE AND PUBLIC HEALTH

was called for, Dr. Edwards made the sad announcement of the

SUDDEN DEATH OF DR. WILLIAM H. COGGESHALL

in Richmond on September 7th, just after he had completed his paper. At the unanimous request of the Society Dr. Edwards read the report, which was entitled

THE RECENT PLYMOUTH EPIDEMIC AND THE LESSONS IT TEACHES.

The writer showed that the epidemic could be traced to the pollution of a stream, from which the water-supply of the town was obtained, by the dejecta of a typhoid fever patient. No attempt had been made to disinfect these stools. This taught us, he said, the necessity of thorough disinfection of all the excreta of patients suffering from zymotic diseases, and also the danger of allowing habitations to be erected on the banks of a stream from which the water-supply of a community is obtained.

Dr. J. E. Chancellor, of the University of Virginia, then read a paper on the

EVILS OF INHUMATION AND ADVANTAGES OF CREMATION,

the title of which indicates clearly the nature of the article. It was an able plea in support of cremation as a means of disposing of the dead.

Dr. Philip Taylor of Richmond, read a report on

ADVANCES IN OPHTHALMOLOGY,

giving a brief *résumé* of the progress which had been made in these branches of medicine in recent years.

Dr. J. A. White, of Richmond. presented some

PRACTICAL REMARKS AND SUGGESTIONS REGARDING DISEASES OF THE EAR, NOSE, AND THROAT.

He emphasized the necessity of prompt treatment of middle-ear disease, spoke of the influence of puberty and the menopause on otitis, dwelt upon the danger of confounding follicular tonsillitis and catarrhal diphtheria, and mentioned the treatment of hay fever by cauterization of the nasal mucous membrane. His remarks were illustrated with the reports of a number of cases.

Dr. Chas. M. Shields, of Richmond, read a paper on

TRACHEOTOMY IN LUPUS OF LARYNX AND DIPHTHERIA.

He related a case of lupus of the larnyx in a man aged fifty-five, and one of diphtheria in a child aged three, in both of which tracheotomy was successfully performed.

Dr. R. C. Cullen, of Henrico County, sent a communication on

INFANTICIDE,

in which he advocated the enactment of more stringent laws to repress this crime.

Dr. L. Ashton, of Falmouth, read a paper entitled

A PLEA FOR TRACHEOTOMY IN CROUP,

in which he urged the more general performance of this simple operation, believing that by this neans the lives of many children could be saved.

EVENING SESSION.

Dr. J. S. Conrad, of Matley Hill Sanitarium, Baltimore, read a paper on the

PSYCHOLOGICAL ASPECTS OF SUICIDE.

Dr. Archer Atkinson, of Baltimore, who was present by invitation, presented a short communication on

IRRITABLE RECTUM.

Dr. Wm. G. Eggleston, of Chicago, reported a case of

GUNSHOT WOUND OF THE HAND.

At the conclusion of this paper, with which the scientific labors of the meeting were concluded, the Society adjourned to the dining-hall of the hotel, where they were entertained at a

COMPLIMENTARY BANQUET,

given by the host, Captain C. A. Colhoun.

AMERICAN GYNECOLOGICAL SOCIETY.

Tenth Annual Meeting, held in Washington, D. C., September 22, 23, and 24, 1885.

(Continued from page 336.)

WEDNESDAY, SEPTEMBER 23D—SECOND DAY—MORNING SESSION.

THE Society was called to order by the President. The following were elected

INVITED GUESTS.

Drs. A. P. Dudley, L. Ernest Neale, Charles H. Riley, Charles O'Donovan, Jr., William E. Moseley, H. S. Bouey, and Joseph B. Plumb, of Baltimore; Dr. J. H. Carstens, of Detroit; Dr. Charles Jewett, of Brooklyn; and Dr. Mary Parsons, of Washington.

THE PRESIDENT called the First Vice-President, DR. William L. Richardson, of Boston, to the Chair, and then delivered

THE ANNUAL ADDRESS.

In the profession of medicine, above all, perhaps, facts are the things which teach, and the intellect, the reason, is the test of truth. The judge who is to discover the truth of complex medical facts and phenomena must be no ignorant prejudiced partisan, biassed by preconceived opinions; but he must be richly endowed with the wisdom of the past, and the rapidly accumulating information of the present, and quick to detect the relations between seemingly dissimilar things. It is not a large number of cases carelessly observed and committed to the treacherous custody of memory, but the comparatively few that are carefully observed, well studied, and honestly recorded, that contribute to establish the great principles of scientific medicine.

Dr. Howard then presented the histories of two rare cases, in which he was unable to make a diagnosis.

CASE I.—S. H——, negress, aged twenty-four years; married; menstruated first at the age of fourteen, which continued regular and normal; was the mother of five children, never had a miscarriage, and her last child was born two months previously. Some days after her last labor she noticed an enlargement of the lower portion of the abdomen, which gradually extended in the median line up to the umbilicus, and was attended by bearing-down pains and frequent micturition. Dr. W. P. Chinn, his chief assistant, detected fluctuation over the entire abdomen, with decided resonance about the umbilical region, and with dulness and bulging in both flanks. Six weeks afterward Dr. Chinn discovered that the umbilical resonance had entirely disappeared, and had been supplanted by dulness, and the umbilicus itself projected forward in the form of a spherical tumor. About two weeks subsequently Dr. Howard saw the patient for the first time, when she had a temperature of 102.5° F.; pulse, 120; respirations, 32. Physical examination revealed pleurisy on the left side. The abdomen was of about the size of that of a woman in the seventh month of pregnancy. There was complete dulness over the entire tumor, unchanged by position, and there was equal fluctuation in every direction. There was no evidence whatever of a solid tumor. The cavity of the uterus measured three and one-quarter inches, and the organ was in front of the tumor.

The President then presented the differential diagnosis relating to ovarian cystoma, fibro-cystoma of the uterus, parovarian cyst, simple ascites, and encysted dropsy of the peritoneum the result of simple peritonitis.

Dr. Howard aspirated the abdominal cyst under antiseptic precautions. The fluid removed coagulated as speedily, and the coagulum was as solid, as that of blood.

After the fluid was removed large hard masses could be felt through the abdominal wall, resembling those felt after tapping a multilocular ovarian cyst, and, according to Atlee, he had to deal with a fibro-cyst of the uterus. But his experience had negatived Dr. Atlee's, and the diagnosis of fibro-cystic tumor of the uterus was again rejected.

The patient rapidly succumbed, with evidence of peritonitis, after the tapping, and the autopsy revealed a case of

ENCYSTED TUBERCULAR PERITONITIS,

which presented the characteristic phenomena of a unilocular ovarian cyst or parovarian cyst.

Dr. Howard then reviewed the literature of tubercular peritonitis, embracing eight cases, in which it could scarcely be said that a correct diagnosis was made in either previous to death.

The second case was that of F. R——, colored, twenty-four years of age, married one year, but never pregnant. General health good, uterine functions normal, no evidence of cardiac or renal trouble. Her abdomen measured, from the ensiform cartilage to the umbilicus, ten and a half inches; from the umbilicus to the symphysis pubis, nine and a half inches; circumference at the umbilicus, forty-six and a half inches; below the umbilicus, forty-seven inches. Distance from the umbilicus to the anterior superior spinous process of the ilium, on the right side, twelve inches; on the left side, twelve and a half inches. The uterus seemed to be pressed forward by a large sac containing fluid, and the sound entered the cavity two and a half inches. The enlargement began about seven and a half years previously, had been free from pain, and gave no special inconvenience to the patient except that which arose from weight and sense of distention.

Microscopical examination of the fluid removed from the tumor in both cases was not resorted to, because Dr. Howard believed that the microscope in the hands of the average microscopist was misleading and untrustworthy. The subsequent history of the case proved it to be one of unilocular cyst, which could not be removed by operation.

The differential diagnosis in this case was studied after the same plan adopted in the first, and also included an extensive *résumé* of the literature of the subject.

The President then returned his thanks to the Society for the honor which it had conferred upon him, and concluded his address with a brief allusion to the "peerless father of American gynecology, J. Marion Sims. It was in this city that he hoped to spend his declining years, and had already made a purchase of a home here for that purpose."

The address was discussed by Dr. T. A. Emmet, of New York, who referred to cases of difficult diagnosis, and also to cases in which great mistakes in diagnosis had been made; by Dr. Busey, of Washington; by Dr. Goodell, of Philadelphia, who thought the President need not be ashamed of having been unable to made a diagnosis until permitted to do so by autopsy; by Dr. Reamy, of Cincinnati, who had a case of death after aspiration of the peritoneal cavity for cystic degeneration of the peritoneum in man, and he also referred to cases of difficulty in diagnosis; and the discussion was closed by Dr. Howard.

THE CARE OF THE PERINEUM DURING LABOR.

DR. THAD. A. REAMY, of Cincinnati, then read a paper on the above subject, in which he said that he who preserves from rupture a perineum which is in peril shows more skill than he who successfully repairs a perineum which has been ruptured. He then referred to the methods which had been recommended for preventing rupture of the perineum, and it was shown that by far the greater number of authorities believed in some method of preservation, and that the method which combined judicious perineal support, with simultaneous re-

tardation of the head, seemed to meet with most favor. The method to be described properly came under the class which combined perineal support and control of the head. It was not recommended in all cases, but only in primiparæ, or in other subjects where the structures were likely to be greatly imperilled.

When the head begins to bulge the perineum, and its distention is such as to indicate peril to its attenuated structures, he places the patient with her back across the bed, with her nates brought to its verge, and takes his seat within easy distance for the necessary manipulations incumbent upon the accoucheur. Then the thighs are flexed upon the abdomen, and the legs upon the thighs, with the knees brought close together, and the limbs are held in this position by two assistants, who may be seated on the edge of the bed, with their backs toward the patient's head; or, if a narrow bed can be obtained, they may take positions on the opposite side of the bed from the accoucheur, which is preferable. These assistants are then given opposite ends of a towel or bandage of linen, about ten inches wide and forty to fifty inches long, which is carried around the buttocks of the patient and spread out smoothly, with its anterior or upper edge on the level of the fourchette. They are then instructed to make traction, during the pains, in such amount and in such direction, and with such part of the bandage as the accoucheur may direct; the direction of the traction may be varied at will, from downward and backward to an upward and forward movement.

The following anatomical and mechanical reasons were given in support of this method of perineal preservation. Recent investigations tend to overthrow the prevailing views concerning the muscles of the perineum (Berry, Hart, and Savage). It has been very generally held that the vagina has a proper sphincter, which is in relation with the sphincter ani by a figure-of-8 continuation, and that there is, just back of the fossa navicularis, a muscular commissure, in the centre of the floor of the perineal body, which also gives attachment to the transversus perinei muscles.

It now seems well established that there is no such fortunate decussation just behind the fourchette; for, if there were, this would be the strongest point of the perineum and not the weakest, as shown by the clinical evidence of its frequent rupture at this point. The firm submucous band felt during parturition at the ostium vaginæ, usually called the constrictor vaginæ, etc., was supposed to be an elliptical muscular ring whose fibres are continuous behind the fossa navicularis. This arrangement of the muscles is taught, and has been, in nearly all of the works of anatomy. Hart shows such a view to have been greatly in error; for, first, the transverse muscles run markedly backward and meet each other at quite an acute angle in the perineal body, and consequently the sphincter vaginæ is not a sphincter at all, but simply a median portion of the two halves of the levator ani as they spread apart and allow exit of the urethra and vagina; these parts of the levator ani are called pubo-coxygeus by Savage. This view of the anatomy is sustained by Cazeaux and Tarnier. Thus it is evident that the median laceration is not required to tear any muscular fibres transversely except a few of the transversei until it reaches the sphincter ani, and in such an injury the skin and fascial fibres only are torn, while the muscular fibres are separated longitudinally.

Suppose two vertical curtains, to use Emmet's simile, whose edges are in contact below and slightly separated above; any attempt to increase the separation at the point of opening by attempting to push a large body between them will manifestly tend to drive them apart below. If this be stayed at the point where they are united below by other curtains below and behind, against the upper edge of which the propelling force is apparently directed, the tendency to separation is greatly decreased. Suppose, in addition, that another transverse curtain is placed over the other two, and, besides, such direction and traction is made upon it as will incline these vertical curtains toward each other we have surely diminished the probability of their separation.

In this method of support the towel properly applied, and the traction successfully directed, plays the part of the third curtain in the illustration, and answers the purpose of a supplemental perineum in practice. It retards the head at the will of the accoucheur by varying the amount and direction of the traction.

This method exerts complete control over the direction of the head, and does not interfere with the use of the forceps or the employment of episiotomy.

The discussion of Dr. Reamy's paper was postponed until the afternoon session.

Afternoon Session.

The Society was promptly called to order by The President.

The discussion was opened by Dr. T. A. Emmet, of New York, who said he had no remarks with regard to supporting the perineum, as he had nothing to do with that line of practice, but wished briefly to give his views regarding the operation for its restoration, and the portion of tissue which he thought was injured whenever the condition called rupture of the perineum existed. In general terms, he held that the perineal body was not ruptured without involving the sphincter ani. First, we should define what the perineum is. If by it was meant all the muscular structure in front of the curve of the rectum, he accepted the definition. Unfortunately, however, the teaching had been otherwise, and that the perineal body was an immense mass of fat, which had nothing to do with the perineum. It is simply the muscular structure in front of the curve of the rectum which should be called the perineum, and when the injury is done it is by the head pushing upon the muscular septum, so that the rectal surface is pushed backward, and the tear is directly behind the entrance to the vagina.

Dr. W. H. Baker, of Boston, had performed Dr. Emmet's last operation since he had been kind enough to describe it to him at the Woman's Hospital, and with very satisfactory results. He regarded it as a very great improvement upon the old perineal operation.

Dr. H. P. C. Wilson, of Baltimore, regarded Dr. Reamy's plan of supporting the perineum as a most rational one, especially as it gave a great advantage to the physician, namely, freedom of his hands for other manipulations.

Dr. M. D. Mann, of Buffalo, thought that Dr. Emmet's recent operation was not applicable to every case of laceration of the perineum; for in some cases there was no tendency to the formation of a rectocele, and there was a direct tear of the structure which exists in front of the rectum. The older operation under such circumstances must be adopted, taking in only the mucous membrane and not the skin, as formerly was done.

Dr. Joseph Taber Johnson, of Washington, referred to one point, namely, the propriety of supporting the perineum at all. Some time ago he had occasion to study the subject, and ascertained as far as possible the effects of parturition upon the perineum, and found that a greater number of cases of rupture occurred among physicians who supported the perineum than among midwives who did not support the perineum.

Dr. James R. Chadwick, of Boston, believed that the term supporting the perineum was a misnomer, and that the various methods described were operative in preventing rupture of the perineum only so far as they retarded the advance of the head.

Dr. Elwood Wilson, of Philadelphia, referred to cases in which he had seen the submucous tissue separated to the distance of one and a half inch before the mucous membrane of the vagina was disturbed at all, and before the head had distended it sufficiently to pro-

duce laceration. In those cases it was utterly impossible to prevent laceration, and the rent extended through the entire perineal body and took place centrally. In such cases he regarded it as impossible to support the perineum so as to prevent rupture.

Dr. J. P. Reynolds, of Boston, thought the statements of women that the perineum had never been ruptured, and that it had not been supported were valueless; for who had examined to determine whether or not rupture had taken place? For many years he had not given the perineum any support except that which came from delay of the advancing head of the child. He advocated the use of anæsthetics.

Dr. Reamy, in closing the discussion, advocated the use of the term perineal support.

Dr. Edward W. Jenks, of Detroit, then reported

A CASE OF CÆSAREAN SECTION,

in which he performed the operation on February 27th last. The woman was twenty-seven years of age, the mother of one child three years old. The case had been reported to the Ontario Medical Association by Dr. J. L. Bray; he was also aided in the operation by Drs. O'Keith and Allen. Three years ago the patient received an accident which fractured the right ilium and produced a deformity of the pelvis which eventually caused her death. Nothing external was seen, and not until an attempt to apply the forceps was made, was the deformity detected. There was a wall of bone on the right side of the pelvis, forming a shelf-like process upon which the fœtus rested. Attempts to deliver with the forceps had failed, and craniotomy had been performed before he saw the case. He deemed it unfortunate that so much manipulation had been made before Cæsarean section was resorted to. The operation was performed in the usual manner, and the patient rallied well. The temperature was normal, the pulse 120, and she was doing well, when on the third day after the operation she died suddenly. He subsequently learned that the patient had a bad dream, and found herself standing upon the floor, and when she was placed in bed she said that she felt as if something had given way inside, and died at the end of about three hours. No autopsy could be obtained.

The paper was discussed by Dr. Skene, of Brooklyn.

Dr. Elwood Wilson, of Philadelphia, then read a paper on

THE USE OF TARNIER'S FORCEPS,

in which reference was made to the protest which he entered to the use of Tarnier's forceps at a previous meeting of the Society. Having, since that discussion, had nine cases suitable for the use of Tarnier's instrument, he renounced before the Society his unjust condemnation of the forceps, and briefly narrated their histories. He offered a few reasons for his change of conviction, and finally believed that no man should condemn on theoretical grounds an instrument in the use of which he had not had practical experience. The modification of Tarnier's forceps devised by Dr. Howard, of Baltimore, was the instrument which he employed in the nine cases, and there was no laceration of either the cervix or perineum.

He thought the instrument applicable in all cases of narrowing of the pelvis, either at the superior strait or at the outlet, and that for all applications of forceps at the superior strait this instrument should be used in preference to Osiander's method of delivery, or in preference to resorting to the dangerous expedient of podalic version; and that they should be applied, if possible, to the sides of the child's head; but, if not, they might be applied obliquely.

The paper was discussed by Dr. Neale, of Baltimore; Drs. Parvin and Goodell, of Philadelphia; Dr. Mann, of Buffalo; Dr. Wilson, of Baltimore; Dr. Reamy, of Cincinnati; and by the President.

THURSDAY, SEPTEMBER 24TH—THIRD DAY—MORNING SESSION.

The Society was called to order by the President.

Dr. R. Stansbury Sutton, of Pittsburg, read a paper entitled

A MODIFICATION OF EMMET'S CERVIX OPERATION IN CERTAIN CASES.

Dr. Sutton reported a case, and said that cicatricial tissue in variable quantity occupies every lacerated cervix of long standing. So long as this tissue is limited to the angle of the laceration it is in small quantity; but the cicatricial tissue is often deposited in larger quantity in the lips of the laceration frequently from border to border. In all these cases, says Dr. Emmet, "were we to simply freshen the surfaces in a superficial manner and attempt to bring them together we should fail to approximate the outer edge properly. Besides, this tissue is cicatricial, is dense, and were we to succeed in obtaining union it would be only temporary, because the previous condition will be reproduced from want of vitality. It is necessary to remove this tissue from the cervix before attempting to secure union. But the removal is not to extend entirely across the flap, because there would be in that case complete closure of the cervical canal."

Dr. Sutton's modification applied to the treatment of those cases in which one flap was involved, and which might be treated by simple denudation with some excavation, while the other flap was so involved that it was necessary to denude its entire face.

In the case reported the anterior lip was longer than the posterior. Ordinary denudation of the posterior lip was sufficient, but the anterior lip required denudation entirely across, and the cicatricial masses removed were exhibited, which extended from below as high as the internal os and from border to border. The lips were then united as usual, and the result had been excellent, the patient having menstruated twice without pain.

Dr. William Goodell, of Philadelphia, said he had resorted to this deviation from the Emmet operation on more than one occasion.

There was another thing he had done in one or two instances, that is, he had dissected up the ribbon of mucous membrane, leaving it attached to the margin of the lip, and then removed the cicatricial tissue beneath it. In the cases in which he had performed this operation there was a very good os, although it was a little smaller than he would have preferred to have had it. He would also state that it had been his rule to dissect out the Nabothian glands so as to get a good surface.

Dr. A. J. C. Skene, of Brooklyn, criticised the use of the term cicatricial tissue, and was confident that it was not cicatricial tissue, but simply hyperplastic tissue, which produces sclerosis. He was also inclined to think that the cicatricial plug, of which so much had been said, in the angle of the original laceration had been magnified.

With reference to the mode of disposing of it, he believed much could be done by preparatory treatment; but sometimes the cervix was so large that too much time would be required to reduce its size in this manner, and then the modification of Dr. Sutton might be adopted. Certainly all diseased Nabothian glands should be disposed of, if possible, before the operation for closure of the laceration. And he thought it better to puncture these cysts during the preparatory treatment.

Instead, however, of doing as Dr. Sutton suggests, he performs an operation as a part of the preparatory treatment, which consisted in removing a V-shaped piece and introducing a couple of sutures on each side of the os externum, and allow the stitches to remain until union takes place, the patient being able to go about after the first day. At the end of a week or ten days remove the sutures, always using silk. Then when the enlarged cervix had been reduced, perform the ordinary operation.

Dr. Elwood Wilson, of Philadelphia, had denuded the entire anterior and posterior lips, and then introduced

a little pledget of lint, allowing it to remain twenty-four hours, and the results had been very satisfactory. He had had undue contraction after the operation in only two cases.

Dr. G. J. Engelmann, of St. Louis, said that Dr. Sutton's modification had thrown new light on this subject. He had encountered the difficulty of which Dr. Sutton had spoken, and, early in the history of the operation had endeavored to overcome it by paring the surfaces, so to speak, whereas he now cut deep and removed a piece, and had frequently found it impossible to preserve the strip of mucous membrane. At first he had a complete agglutination of the entire surface, but the introduction of a probe on the third or fourth day, and again on the eighth or ninth day, had kept the passage open, and during the last few years he had paid no attention whatever to the central strip.

Dr. J. Taber Johnson, of Washington, thought the Society indebted to Dr. Sutton for the point brought forward, although it had been practised by others, yet had not been published. He had had the same trouble referred to by other speakers in treating the undenuded portion, it being unhealthy and covered with a peculiar condition of the mucous membrane. He removed it in one case, and had considerable difficulty in keeping the pledgets of cotton in position, introduced for the purpose of preserving the integrity of the canal.

He wished, in connection with this subject, to make a public statement with reference to statistics which he published some time ago concerning the danger of Emmet's operation, and in which he feared he had done injustice to the statistics furnished him by Dr. Goodell, of Philadelphia. He had added three to the list of fatal cases, taken from Dr. Goodell's statistics, but had since learned that those deaths were not in any way traceable to the operation.

Dr. M. D. Mann, of Buffalo, said there were several classes of cases which came into the discussion of this subject. Ordinarily the anterior lip was very much hypertrophied, and the posterior was normal or even slightly atrophied. In this case it was difficult to bring the two lips together, and Dr. Emmet's method was to cut into the anterior lip somewhat deeper toward the front part, making the flap long, then bringing the lips together. Dr. Mann had tried that method with good results. He had also tried the method suggested by Dr. Sutton, cutting tissue out of the anterior lip until it was reduced in size so as to correspond with the other lip, and then bringing them together, and it had given very good results. He had not encountered any case in which contraction, such as spoken of by Dr. Skene had occurred.

With regard to Dr. Engelmann's statement, that he cuts very deeply in some of these cases, Dr. Mann would be afraid to do so because of the tendency to uterine version, and if all of the cervix were cut away there would not remain any handle by which the uterus could be kept in proper position by means of a pessary. The plan, however, might give better results than it would seem to do theoretically.

Dr. Goodell, of Philadelphia, was very much obliged to Dr. Sutton, and also to Dr. Johnson, for reference to his cases, and then gave briefly the clinical histories of the three cases referred to by Dr. Johnson in his paper. As already stated, one patient died from the effects of the ether. In the second there was found a gummatous tumor at the base of the brain, and the third died from causes entirely independent of the operation.

He would ask Dr. Sutton if he had ever seen any cases of retroversion, as he had seen, cured by Emmet's operation?

Dr. W. H. Baker, of Boston, thought it hardly fair to regard as a modification of Emmet's operation the procedure which Dr. Sutton had described, as it was rather giving up the fact that Emmet's operation could be or could not be performed in any given case, and going back to the performance of partial amputation of the cervix. It seemed to him that if Dr. Sutton's proposed modification was adopted, the result would be a curved canal. If the patient is thoroughly prepared before the operation, and if these hyperplastic lips remain greatly enlarged, it becomes a question whether we can perform Emmet's operation, and whether we can approximate the opposed surfaces and bring them into perfect apposition. Dr. Baker believed that it could be done in every case. He thought it could be done exactly as Dr. Skeene had described, except that he would not agree that it was necessary to perform it as a preparatory operation; for as a preparatory operation a much larger **V**-shaped portion must be removed in order to approximate the surfaces.

Dr. Engelmann remarked that the involution of the uterus after these operations was much more marked when a large portion of the indurated surfaces was removed than when the cervix was simply trimmed, and that it was the final result which should be aimed at much more than simple union of the surfaces.

The President referred to the fact that it was Dr. Sims' mode of practice to remove a large portion of the hyperplastic tissue and insert a small glass tube, fitting so lightly that it would drop out if not sustained by a cotton tampon, and which was renewed every day until it was no longer necessitated.

Dr. A. P. Dudley, of Baltimore, an invited guest, said that it was Dr. Emmet's custom, when one lip was very much more hypertrophied than the other, instead of leaving the angle where it is, to change the angle of the laceration upon the other lip, whichever was the longest, and thereby do away with the necessity of cutting out a strip.

Dr. Skene further remarked that when denudation entirely across the flap was practised upon both sides, stenosis would sooner or later occur. He was in favor of leaving the mucous membrane upon one side at least, and if possible upon both. He believed with Dr. Baker that the aim of the surgeon should be to preserve, as far as possible, the original cervix, and that the abandonment of Dr. Emmet's operation and practising amputation was not by any means the highest art; it was simply a deviation which might become necessary.

Dr. Sutton, in closing the discussion, accepted the criticism, with reference to the term cicatricial tissue. With reference to the cure of retroversion by operations upon the cervix, he had observed it in his practice.

INFLAMMATION OF THE PAROTID GLANDS FOLLOWING OPERATIONS UPON THE FEMALE GENITAL ORGANS.

Dr. William Goodell, of Philadelphia, read a paper on the above subject, in which he gave the histories of cases which seemed to him to give evidence of the sympathetic relation existing between parotid bubo following operations upon the female genital organs. Schroeder had reported five cases of parotid bubo, with two deaths in two hundred cases of ovariotomy. In one hundred and fifty-three ovariotomies performed by himself, one case of parotid bubo had occurred, of which he gave the history. These were cases of symptomatic parotid bubo, but he believed that there were other cases sympathetic, and not septic in character, as there was no evidence of septicæmia, and the swelling did not suppurate. Of these he gave an illustrative case, which had already been reported in the *American Journal of Obstetrics*.

In his third case both glands were involved, following oöphorectomy, and this was reported in the Philadelphia Obstetrical Society, October, 1884. Since that time his observations had been confirmed by Angus McDonald and others, that the condition was one of sympathy and not symptomatic; that there was a kinship between the adult genital apparatus and the parotid gland, and that the existence of the two conditions was something more than a mere coincidence.

Dr. Sutton, of Pittsburg, referred to a case of ovariotomy occurring in his own practice, in which the parotid glands became inflamed, did not suppurate, but the patient died.

Dr. J. Taber Johnson, of Washington, referred to a case of ovariotomy in which his patient died on the sixth day after the operation, with a slight rise of temperature, glassy expression of the eye, and an inflamed parotid gland, but no suppuration.

Dr. M. D. Mann, of Buffalo, wished to put on record three cases of this complication. In one there was distinct septicæmia, and the patient died before suppuration of the gland took place. In the second the parotitis appeared after removal of both ovaries and the uterus, the patient recovering, and the third case occurred after a wound of the abdomen in a man. He had regarded the complication as one which might follow abdominal wounds rather than wounds referred distinctly to the sexual organs.

Dr. T. A. Emmet, of New York, added to the list two cases; one following the operation for laceration of the cervix, and the other following the operation for closing an insignificant vesicle over a vaginal fistula. In the last case the patient died, it being the only case in which he had ever known a patient to die after the operation for vesico-vaginal fistula. He had not seen it after ovariotomy.

Dr. Baker, of Boston, added one case, which occurred after Tait's operation. There was suppuration of the left parotid gland, thought to be of septic origin, but the patient ultimately recovered.

Dr. Reamy, of Cincinnati, had seen two cases of inflammation of the parotid gland after operations. The first was after Tait's operation, in which the patient died, and the gland did not suppurate. The second was one of supravaginal hysterectomy after removal of both ovaries and the tubes, in a woman fifty-four years of age. The left parotid gland was very much enlarged, but did not suppurate, and the patient, after a long time, recovered.

Dr. Goodell said that it was well known that parotid bubo might follow surgical operations, and such diseases as typhoid fever, scarlet fever, etc.; but the point in his paper he thought had been sustained by the cases related by the gentlemen who had taken part in the discussion. The complication is exceptional after surgical operation, but he thought it was more apt to occur after operations upon the sexual organs, and he could not help but think that some of them were entirely free from septic poisoning. If the temperature does not rise, and the pulse does not show much sympathy, he should regard the disease as sympathetic, and would not worry concerning the case as he had done formerly.

Dr. James R. Chadwick, of Boston, read a paper entitled

PERISTALSIS OF THE GENITAL TRACT,

and related the histories of two cases in which the question arose, Why should contractions of the womb lead to relaxation of the vagina? The problem was one of physiology, not of physics; for in neither instance was there any mechanical distention. An elucidation of this law he believed might be obtained by analogy with other organs having similar structures and functions. Dr. Chadwick then referred to his paper on the so-called functions of the anal sphincter and the act of defecation, in which he made the point that this physiological act applied equally well to the so-called third sphincter and the internal sphincter which contracted behind the anal sphincter, and acted, not as a sphincter, but as *detrusor es fecium*, a view that has met with general acceptance.

With reference to the *bladder*, Dr. Chadwick had observed that in cases of irritable neck pressure upon and irritation of the full bladder, through the abdominal wall, had, in certain cases, failed to cause evacuation of the urine until peristaltic action had been set up in the walls of the bladder, as was manifest to the touch through the abdominal walls. Peristalsis in these two organs does not take place in identically the same manner, but differs to meet the special requirements.

In the *intestines* there seems to be contraction of the muscles throughout the entire circumference of one segment of the tube during a brief period of time.

Each form of peristalsis is specially adapted to the different character of the contents of each viscus.

Dr. Chadwick then presented the grounds for attributing an analogous function to the genital tract. The Fallopian tubes, uterus, and vagina must be considered as one tube; the walls of all three consist mainly of two layers, arranged, one longitudinally and the other transversely, the disposition being the same as in the bladder and intestines; the muscles are unstriped as in the other organs, and the contractions of these muscles also are under the influence of the spinal and ganglionic system of nerves, and occur rhythmically. Those of the vagina in woman have not been hitherto observed or recorded, but may from analogy be supposed to follow the same law. Or, if to a certain extent the theory has been recognized, its importance has not been adequately appreciated. Dr. Chadwick then referred to the literature of the subject, and believed that he had established a presumption in favor of the explanation of the vaginal relaxation, and would insist that peristalsis is the normal mode of action of each and every division of the genital tract, and that many phenomena and many symptoms can only be correctly interpreted by reference to this mode of motion. Vaginal colic must be rare, yet its assumption would also explain the peculiar symptoms in two or three cases which he could recall. Tubal colic, in various degrees, he believed to be of very common occurrence, but not easily demonstrable. He believed it to be the true morbid phenomena which gives rise to most of the lancinating pains which are usually denominated ovarian neuralgia.

The paper was discussed by Dr. Goodell, of Philadelphia.

Dr. Theophilus Parvin, of Philadelphia, then read a paper on

FACIAL PARALYSIS IN THE INFANT FROM THE USE OF THE OBSTETRIC FORCEPS.

Dr. Parvin related the history of a case occurring in a primipara thirty years of age, who had chronic Bright's disease. The presentation was vertex, the position left occipito-anterior. Davis's forceps were used, and a living child, feeble, weighing seven and a half pounds, was delivered. On the following day, when the child cried the right side of the face presented the usual appearance of facial paralysis; but it scarcely interfered with nursing, and at the end of ten days had disappeared without treatment. Not all cases, however, terminate in recovery.

Dr. Parvin then gave a *résumé* of the literature of the subject. The average period of recovery after forceps delivery is six weeks. Cases also occur spontaneously, and in practice they are to be differentiated. In the great majority of cases the condition is due to compression of the seventh pair nerves.

With regard to treatment, nothing is to be done in the first few weeks. Later, electricity, counter-irritation, etc., have been resorted to. We should be cautious, however, concerning prognosis; probably it will recover spontaneously, and treatment should be begun after the expiration of two months, if recovery has not then taken place.

Dr. Elwood Wilson, of Philadelphia, had seen this result from the use of forceps in a number of cases; he had no recollection of its spontaneous occurrence. He had never seen it after prolonged, hard labors *unaided*. He thought he had seen it most frequently where the head of the child presented in the right side of the pelvis, and that it had been due to a failure to carry the forceps sufficiently high upon the child's head.

Dr. Goodell, of Philadelphia, said that in every case in which he had seen it the paralysis had been upon the right side of the face, and he had not seen it in *unaided* labors.

Dr. Skene, of Brooklyn, had been interested in the question of differential diagnosis between cases of spon-

taneous origin and those following the use of, and probably due to, pressure of the forceps. As a rule, there was but little difficulty, except in a complication consisting of paralysis of the facial nerve with paralysis on the same side of the face and arm produced by injury in delivering the shoulder. In other words, it is difficult to differentiate between paralysis produced by injury done by forceps and the paralysis which often occurs, in tedious labors, from apoplexy.

Dr. Richardson, of Boston, said that all the cases which he had seen had recovered spontaneously within three weeks, and that the paralysis had in nearly all been upon the right side. He had seen two cases in which it followed the use of forceps to complete delivery after version.

Dr. Parvin thought the histories of the cases he had given, and the remarks which had been made, confirmed the suggestion that it is that side of the face which is lower, the head descending somewhat obliquely, that is most liable to be compressed.

A paper on "The Genu-pectoral Position in the Prolonged Nausea and Vomiting of Pregnancy," by Dr. Henry F. Campbell, of Augusta, Ga., was read by title.

Dr. Joseph Taber Johnson, of Washington, offered a resolution extending the sympathy of the Society to ex-President Albert H. Smith, of Philadelphia, in his sickness, attended with unusual suffering, and expressing the hope that he might be speedily restored to health.

Seconded by Dr. H. P. C. Wilson, of Baltimore, and unanimously adopted.

The retiring President then called to the chair the President-elect, Dr. Thad. A. Reamy, of Cincinnati, O., who thanked the Society for the great honor it had conferred upon him, and promised to work honestly and with his whole ability for its continued prosperity.

On motion by Dr. Wilson, of Baltimore, the thanks of the Society were unanimously voted to the retiring President for the faithful and impartial manner in which he had discharged the duties of his office.

On motion by Dr. Goodell, of Philadelphia, the Society unanimously returned its thanks to the late Secretary, Dr. Frank P. Foster, of New York, for the able manner in which he had performed his duties, and expressed the regret that he was no longer able to accept the office.

On motion by Dr. Richardson, of Boston, the Society adjourned to meet in Baltimore, September 21, 22 and 23, 1886. The following were elected officers for the years 1885 and 1886:

President—Dr. Thad. A. Reamy, of Cincinnati.

Vice-Presidents—Dr. Theophilus Parvin, of Philadelphia, and Dr. George J. Engelmann, of St. Louis.

Secretary—Dr. Joseph Taber Johnson, of Washington.

Treasurer—Dr. Matthew D. Mann, of Buffalo.

Council—Drs. Frank P. Foster, of New York; B. B. Browne, of Baltimore; John C. Reeve, of Dayton, O.; and R. B. Maury, of Memphis, Tenn.

The following were elected to active fellowship: Dr. James B. Hunter, of New York; Dr. Charles Jewett, of Brooklyn; and Dr. W. H. Parish, of Philadelphia.

Dr. W. S. Playfair, of London, England, was elected an honorary fellow.

The Careful Patient.—The following joke is at the expense of a Chicago doctor. He was about to anæsthetize a patient, when, in answer to a question, he informed the victim that he would be entirely unconscious and know nothing until the offending growth had been removed. The patient accordingly commenced to fish his loose change out of his pocket. "Oh, you need not mind the fee until I am through," remarked the considerate doctor. "I don't intend to pay you yet," returned the patient, "I wish merely to count my money, to see how much I have." The doctor saw the point and was much amused.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE COURSE OF STUDY IN THE LONDON MEDICAL SCHOOLS NOW AND TWENTY-FIVE YEARS AGO.

London, September 15, 1885.

In another fortnight the medical schools will reopen, and the various medical and scientific societies will not be long in imitating their example. By the first of October, also (that day sacred to introductory lectures), most doctors who have been away to recruit themselves will have returned for the winter. By the time this appears in your columns, therefore, medical London will have reassumed its normal activity.

The curriculum of the London medical student differs in some respect from that of his American confrère in New York, Boston, Philadelphia, or other medical centres in the United States. That it is different from that of most Continental schools, goes without saying, though it is equally obvious that there must be some resemblance between all well-equipped schools of medicine. Dublin and Edinburgh, and the other Scotch and Irish schools, have each their own peculiarities on which I do not now propose to dwell. I will briefly describe the ordinary course of study in one of the metropolitan medical schools, merely premising that my account does not apply to any one medical school in particular, but to metropolitan medical teaching in general. With a few variations it may be taken as applying to most of the provincial medical schools also.

The minimum course of study for all diplomas and degrees now consists of four years. Each *annus medicus* at a medical school is divided into two sessions, viz., a winter session (October 1st to March 31st, with a vacation at Christmas), and a summer session (this begins May 1st and terminates from the 15th to the 31st of July, according to the school). Of this period of four years, at least three winter sessions and two summer sessions must be passed at a recognized medical school; the remainder of the time may be spent in pupilage with a medical practitioner or otherwise. For the higher examinations the whole period of four years must be spent at a medical school. For its Fellowship, the College of Surgeons requires a curriculum of six years, except from candidates who have been eight years in practice. The University of London requires a preliminary year to have been spent in the study of science, and the General Medical Council have lately advised that this plan should be adopted by all students. It is scarcely necessary to remark that candidates for the more difficult examinations often voluntarily lengthen their curriculum beyond the minimum of four years, and that students who only purpose going in for the ordinary diplomas may have it (involuntarily in their case) lengthened for them by failure at one or more examinations.

On entering at a medical school a student has to register himself as a medical student at the office of the Medical Council. Before being allowed to register he has to produce a certificate of having passed a recognized examination in the subjects of general education. He then commences his studies. Most students commence medical study in October, though some prefer to begin with the summer session, and the number of those who do so is apparently increasing. During the first two winter sessions, anatomy and physiology (including histology) form his chief subjects for study. During his first winter, however, he has also to attend lectures on chemistry, and during his second, courses of lectures on medicine and surgery. Anatomy is studied by means of lectures, practical demonstrations, and dissections. During his first two winters an average student generally manages to dissect the whole body once, and, if industrious, can generally contrive to do some parts twice.

Bodies for dissection are now always injected, and some preservative fluid (mixed with some coloring matter) is usually employed for the purpose. At many schools the students still further preserve their "parts" by wrapping them up in cloths dipped in methylated spirit or carbolic lotion—a piece of mackintosh being placed round this to prevent evaporation. In some of the dissecting-rooms, though, the dissectors make no attempt to check putrefaction, but when their "part" has gone bad, get another. Histology is taught by means of practical demonstrations. Physiology is taught mainly by means of lectures, though there are classes of practical physiology (apart from histology) at some schools, and a few have well-equipped physiological laboratories for study and research. Still, instruction in practical physiology is far from being as thorough as is that in practical anatomy. Take, for instance, the chemistry of the urine. At some schools, at any rate, the average student makes his first *practical* acquaintance with this subject when he comes to his clinical work. Still, improvement is going on in methods of instruction, and physiology is not only farther advanced, but is taught much more thoroughly than it was five or ten years ago. An elementary examination in anatomy and physiology has (according to the new Conjoint scheme) to be passed at the end of the first winter session.

The first summer session is devoted to the attendance on lectures on materia medica and botany, and to the practical study of chemistry in the chemical laboratory. The ordinary course of practical chemistry includes the detection of the inorganic acids and bases, and the use of the blowpipe. General chemical manipulation is taught, and, in some schools, the practical preparation of gases, etc. Most schools now have a voluntary advanced class for studying practical organic chemistry. The materia medica museum is usually frequented during the first summer session, and also the hospital dispensary, to learn dispensing, unless this has previously been learnt. At the end of the first summer (or sooner, if he can produce certificates of having received instruction in the subjects) the student can present himself for examination in chemistry and physics, materia medica and pharmacy, and medical botany.

During the second winter anatomical and physiological work is pursued with redoubled zeal, in view of the examination which should be passed at the end of the winter session. As the latter draws near, special classes are usually held to prepare for the coming ordeal, and at some schools it has been customary to refuse the necessary certificates of attendance to students who have not satisfied their teachers of their proficiency. At no metropolitan school, however, so far as I am aware, are the dissecting-rooms open after 5 P.M. Evening instruction of any kind, except in private classes, is unknown in the London schools.

Having passed his examination in anatomy and physiology the student is now at liberty to turn his attention to clinical work, of which he has hitherto seen little or nothing. He may have paid an occasional visit to the wards and had stray glimpses of the operating theatre, but his attention has been almost entirely monopolized by the earlier subjects. If he be going in for the F.R.C.S. he must pursue these for yet another year; and if he intend presenting himself for the London University examinations he will frequently elect to devote an extra year to anatomical and physiological studies conjoined, in the latter case with materia medica and chemistry. In either of these cases he will defer clinical study for the present. Presuming, however, that he is merely going in for the ordinary diplomas, his second summer session will see his introduction to the wards. During this session he will have also to attend lectures on midwifery and medical jurisprudence, but these will not absorb much of his time. During these three months an attentive student can pick up a good deal of clinical knowledge. A dresserships in the out-patient department is often held at this time.

During the third winter session lectures on medicine, surgery, and pathology are attended. Clinical work is now attacked in good earnest. Some hospitals have medical tutors attached to them, whose duty it is to impart elementary clinical instruction to students preparatory to their appointment as clinical clerks and dressers. At others, students are sent straight into the wards and left to learn what they can. In the latter case, they usually get some elementary instruction from the house-physicians and house-surgeons. At some hospitals the post of surgical clerk is conjoined with that of dresser; at others it is a separate post. Three or four months is the usual period for which these clinical appointments are held, though a second or third term may sometimes be obtained. The facility with which dresserships and clerkships can be obtained varies considerably at different hospitals, depending partly on the size of the hospital, and partly on the number of students. Clinical appointments are free at most hospitals; at others they have (some or all) to be paid for. Out-patient appointments sometimes precede, sometimes follow, in-patient ones. At Guy's Hospital the in-patient dresserships are usually held by students who have obtained their diplomas, and they take almost entire charge of the cases, the duties of the house-surgeons being confined to the maintenance of a general supervision and the administration of anæsthetics. Clinical appointments can be held in the various special departments, which are now very numerous.

Midwifery cases have often been attended during a period of preparatory pupilage, though this method of commencing medical study is decidedly on the wane. Some students get some insight into midwifery practice while holding temporary assistantships during vacations. Those who have not had any midwifery practice can get cases assigned them in the maternity department of their hospital. At some hospitals (*e.g.*, the London and St. Thomas') arrangements are made for the obstetric clerks to reside in the hospital during their fortnight on duty; at others they are summoned from their lodgings.

At the conclusion of his fourth year of study the student can present himself for his final examination in medicine, surgery, and obstetrics, including pathology and therapeutics. This is partly written, partly *viva voce*, and partly clinical and practical. The three subjects may be taken either together, or, if wished, singly.

Many changes have taken place in the curriculum within the last quarter of a century. Twenty-five years ago the curriculum was only three years, and there was only one examination for the membership of the English College of Surgeons. This only occupied an hour, and was entirely *viva voce*. Practical examinations in anatomy and histology, and clinical examinations in medicine and surgery, with questions on morbid specimens are all modern innovations not only at the College of Surgeons, but elsewhere.

SHALL WE FOLLOW ONE LINE OF TREATMENT OF GUNSHOT WOUNDS?

To the Editor of The Medical Record.

SIR: In THE RECORD of September 12th there appears an article of seven pages on the above subject. The writer of it has not had that extensive experience that we should have desired in such an article; but, perhaps, to the readers this is a gain, as he does not thus prejudge conclusions with special treatments of his own, simply chronicling the very extended lines of experience of the distinguished European military surgeons in recent wars; therefore the article is, to a certain extent, instructive.

The author evidently favors, generally, primary antiseptic occlusion. Casting aside personal predilections as to this or that special way of treating, we see that success is recorded, by means of diametrically opposite treatments, in the careful hands of distinguished authori

ties. It is also well known generally that wounds, in their after-behavior, must be classified in at least two large divisions. With what reason, then, can the writer favor a treatment to be generally pursued which can only be followed in one of these divisions?

Like many other medical practitioners, doubtless, I have slowly and carefully read works on military surgery written by celebrated authorities; also similar articles in the medical press. I think the more we read on this subject, the more convincing it is that certain wounds require one treatment, while other wounds require other treatments.

A dogmatic assertion that nearly all wounds can be brought to a successful issue by simply applying an antiseptic dressing, whether in the hands of a nurse, office-boy, or doctor, letting everything else take care of itself, we opine is untenable. The idea that down in the depths we can leave a heavy Remington bullet, crushed bone, crushed muscle, lacerated and crushed arteries, leave them with complacency, and put a carbolized rag over the outside hole or holes, is a pleasant one to the surgeon. A chest-wound has usually been regarded as serious, as well as cranial wounds; but remarkable results have been obtained in both instances by drainage; good results are also had by leaving alone; this is where a good surgeon is expected to use his judgment, and not merely an antiseptic rag.

With regard to abdominal and pelvic wounds, the case is widely different. As a preliminary remark, a limited number of wounds of these cavities by both bullet or blade have recovered. But we think the indication undoubtedly should be to perform laparotomy; if the ball is not soon found, it may be left, as it will likely do little harm. The chief danger consists in intestinal wounds; their edges should be freshened, then brought together in the manner practised by Dr. Bull, of this city; severed, or even brushed, vessels should be tied, as a brushed vessel, under inflammatory reaction, may cause serious secondary hemorrhage, imperilling the success of the whole operation; finally, drainage may, or may not, be employed.

A small effusion of simple or of bloody serum will not imperil the patient. Dr. Raymond thinks that a pint of bloody serum is serious; a pint of fluid spread out in the abdominal cavity would make very little show. There are many cases of effusion in peritonitis and in pleurisy where the patients have recovered after the effusion of more than a pint.

Statistics are often delusive for many side-reasons: post-mortems, unfortunately, are often delusive from the imperfect diagnostic powers of those who perform them; the dead body is there as convincing but silent evidence, but the correct diagnosis is not there.

The correct treatment of wounds has been carefully considered from the time of Hippocrates, down through the Middle Ages to the recent times of Larrey, Guthrie, Langenbeck, and Esmarch; in the way of occlusion Larrey (when it was proper to do so) employed a gently stimulating compress of wine and white of egg; while Richardson, of London, has obtained excellent results with his "styptic colloid."

Thus we see it is eminently proper that we should not follow only *one* line of treatment.

Reproduction of Harvey's Original Lectures.—The transcribing and reproduction of Harvey's original MS. lectures, delivered before the Royal College of Physicians in 1616, containing the first suggestion of his discovery of the circulation, are proceeding uninterruptedly under the active supervision of Mr. Scott, of the British Museum, the *fac-simile* work being entrusted to the Autotype Company. The cost to subscribers is fixed at two guineas, and the work is expected to be ready for delivery in the spring of next year.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 20, 1885, *to September* 26, 1885.

McParlin, T. A., Lieutenant-Colonel and Assistant Medical Purveyor. Promoted to be Surgeon, with rank of Colonel, to date from September 16, 1885.

Irwin, B. J. D., Major and Surgeon. Promoted to be Assistant Medical Purveyor, with rank of Lieutenant-Colonel, to date from September 16, 1885.

Pope, B. F., Captain and Assistant Surgeon. Promoted to be Surgeon, with rank of Major, to date from September 16, 1885.

Morris, Edward R. Appointed Assistant Surgeon, with rank of First Lieutenant, to date from September 17, 1885.

Ainsworth, F. C., Captain and Assistant Surgeon. From Department of Texas to New York City, for duty as Recorder of the Army Medical Examining Board. S. O. 214, A. G. O., September 18, 1885.

Adair, G. W., Captain and Assistant Surgeon. Granted leave of absence for one month, with permission to apply for one month's extension. S. O. 104, Department of Dakota, September 18, 1885.

Shannon, Wm. C., Captain and Assistant Surgeon. Granted leave of absence for four months, to take effect about October 1st. S. O. 215, A. G. O., September 19, 1885.

Bushnell, Geo. E., First Lieutenant and Assistant Surgeon. Ordered from Department of Dakota to Department of the East. S. O. 219, A. G. O., September, 24, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending September 26, 1885.

Dungan, J. S., Medical Director. Waiting orders.

Medical Items.

Epidemic Pneumonia.—S. Triwus, a district medical officer in St. Petersburg, communicates to that *Vrach* an account of an epidemic of pneumonia in the city. From April 26th to May 17th, out of 133 patients seen by him 23 had croupous pneumonia (17.2 per cent. of the whole). In one dwelling there were 3 cases, in another 2; in one house there were 4, in another 3, and in two 2 cases. Sixteen of the patients lived in houses with gardens.

Teacher: "So you can't do a simple sum in arithmetic. Now, let me explain it to you. Suppose 8 of you have together 48 apples, 32 peaches, and 16 melons, what will each one of you get?" "Cholerer Morgus," replied little Johnny Fizzletop, who is addicted to that malady.—*Texas Siftings.*

The Relative Fatality of Charcoal Fumes and Illuminating Gas.—Drs. Biefel and Poleck have recently discussed in the *Zeitschrift für Biologie* the question of the relative fatal effects of charcoal fumes and of illuminating gas, it being asserted that in the former case .19 per cent. in the air of CO destroys human life in thirty-five minutes, while a limit of one per cent. is exceeded in the latter case before a similar result ensues. This is attributed to the presence of oxygen in the gas; but Dr. Wagner has disputed these conclusions on the ground that the experiments were not conducted in a satisfactory manner. He agrees, however, with the statement that a mixture of gas and air possessing fatal properties is necessarily in an explosive condition.

Another Cure for Hiccough.—A writer in the *Bulletin Générale de Thérapeutique* says that refrigeration of the lobe of the ear will stop hiccough, whatever its cause may be. Very slight refrigeration, such as a drop of cold water, is said to be sufficient.

WOUND OF THE BASILAR PORTION OF THE BRAIN.[1]

BY PHILIP ZENNER, M.D.,

CLINICAL LECTURER ON DISEASES OF THE NERVOUS SYSTEM, MEDICAL COLLEGE OF OHIO, CINCINNATI, O.

THE patient, a man forty-two years of age, had always enjoyed good health previous to the time of injury. On July 11th, nearly eleven weeks ago, while leaning forward in the show-case of a millinery establishment, a transverse bar, upon which he was supporting himself, gave way, and precipitated him upon a sharp-pointed iron rod used for holding hats. This rod is about one-quarter inch in diameter, smooth and round, and within about an inch of the end begins to taper to a point. It penetrated the skin in the right submaxillary region, about one and one-third inch to the right of the median line, the point passing four inches beyond the surface. Its direction, according to the statement of lookers-on, was upward, and somewhat inward and backward. The rod was held very firmly in a fixed position, as if between unyielding tissues, and was only removed after a very forcible effort made by a powerful man.

Patient's wife states that he rose immediately after the fall, and continued on his feet until after the rod was removed, some minutes later. Shortly afterward, while removing him to his room, they observed that he did not move his right arm and leg. He did not speak from the moment of the fall.

The speaker saw the patient perhaps one-half hour after the accident occurred. There was still slight oozing of blood from the wound, from which perhaps an ounce of blood had escaped. Patient was lying in bed, breathing regular, but somewhat stertorous; pulse regular, about eighty beats to the minute. There was complete paralysis of the right upper and lower extremities, of the tongue, of the muscles supplied by the lower branches of the facial nerve in both sides, and the patient could not swallow or give utterance to any sound, either articulate or non-articulate. But he was conscious, and, to some extent, could answer questions by the movements of the left hand or the eyeballs. There was no paralysis of the muscles supplied by the third, fourth, sixth, and upper branches of the seventh nerves. The pupils were normal, the eyes could be equally moved in every direction, and could be readily opened and closed. There appeared also to be no impairment of hearing or vision.

The patient was exceedingly restless and seemed to suffer much with pain in the left side of the face. A few days later, anæsthesia in the area supplied by the upper two branches of the left trifacial nerve was observed, which was probably present in the beginning, but not detected, although an unsatisfactory examination of the cutaneous sensibility was made at that time.

In addition, it was observed that the lower jaw was turned to the left side, so that when the jaws were approximated the right central incisor of the lower jaw corresponded to the left central incisor of the upper jaw. This condition still remains. At first I thought it was due to paralysis of the right pterygoid muscle, but now believe it to be a surgical trouble.

[1] Read before the Cincinnati Academy of Medicine, September 21, 1885.

The condition of the patient improved very rapidly. The external wound healed in a few days. At no time was there any evidence that the rod entered the buccal or pharyngeal cavity. There was slight fever, temperature never rising above 101.5° F., on the second and third day; none subsequently.

On the second day patient succeeded in swallowing a few drops of water and moved the right leg a little. On the fourth day he was able to make a slight vocal, and even articulate, sound. On the sixth day he moved the right arm a very little. On the eighth day he swallowed so well that rectal injections of food, which had previously been given, were discontinued. At the end of two weeks he could speak single words with some distinctness, though continuous speech was impossible on account of difficulty of articulation; he could walk with the assistance of a cane; the muscles of the left side of the face seemed to act quite normally, while there was still paresis of the right side; the tongue was easily protruded, but was deflected slightly to the right. There had been almost a constant dribbling of saliva from the mouth, but this became much less.

He continued to improve for about six weeks, when his condition was at its best. Since then there has been some change for the worse. His speech is less distinct, and the power of the right extremities less than a few weeks ago. The anæsthesia on the left side of the face is greater. It appeared at first to be only in the area supplied by the upper branches of the fifth, and even in that area sensations of pain were still felt. Now it seems to cover almost the whole area covered by the fifth nerve, extending from the middle of the vertex to below the lower margin of the inferior maxillary bone, and from the median line to the left ear, the latter retaining its sensibility. In this area tactile sensibility, as well as that to temperature, is lost, and the prick of a pin is only felt in a few isolated spots. The left nares, and left side of the mouth and tongue are anæsthetic, and the sense of taste is lost in the left side of the tongue. In addition to this, the subjective symptoms seem to be much worse than they were. He complains constantly of pain or uncomfortable sensations of some kind in the left side of the face.

Another symptom has appeared recently—polyuria. For three or four weeks he has been passing an excessive quantity of urine. Eight days ago he passed two hundred and eight ounces, and its specific gravity was 1.001. The quantity has been gradually diminishing since. At present it is eighty ounces, specific gravity 1.010. It does not contain sugar or albumen. Several times I examined the electrical reactions of the paralyzed muscles, which were always found to be normal.

There is now considerable dragging of the right foot in walking. Grasp of right hand is feeble, the extensors of fingers almost completely paralyzed. The tongue, when protruded, deflects slightly to right. There is slight paresis of the face on the right side. The articulation is much more indistinct than in ordinary cases of hemiplegia, at least at so late a date. There is no aphasia. Patient can name any object accurately. There is complete anæsthesia in area of the left fifth nerve, left corner is anæsthetic, etc. There is also some injection of the left conjunctiva, more or less bleeding from the left nostril, and an abraded surface in its exterior part, and a slight abrasion on left side of tongue.

The early symptoms of paralysis of the vocal cords, in-

ability to swallow, etc., are bulbar symptoms and point to a lesion in the neighborhood of the medulla. They were mostly indirect symptoms, and therefore disappeared. Of the remaining symptoms the paralysis of the left fifth nerve is of decided local significance, and points to a lesion in the nerve-roots or its nuclei. It is possible that there are several lesions present; but one on the left side of the medulla or pons, involving either the ascending root of the fifth nerve, or the nerve-trunk itself, might account for the symptoms. In that case the pyramidal tracts and the right hypoglossal and facial nerves must have been affected on the left side, the former before it crosses over to the right side of the cord, and the latter in their central prolongations before they have crossed over to their respective nuclei. The lesion must then reach above the level of the seventh nerve, and, in that case, it is difficult to understand how the third, fourth, and sixth nerves should have been altogether spared, even in the beginning, when so many indirect symptoms were present. Perhaps only a small part of the lesion reaches to this high level, and thus the absence of symptoms are to be accounted for. The lesion must have also avoided the sensory track for the opposite side of the body, and perhaps encroached upon the particular lesions which are followed by diabetes, that is, the floor of the fourth ventricle above the nuclei of the pneumogastrics. Just how this lesion was produced is very problematical. There are good reasons for believing that the rod penetrated the cranial cavity between the atlas and occipital bone. This is the only place through which it could reach that cavity without fracturing bone, and the symptoms did not indicate any fracture. The rod entered four inches beyond the surface, and various calculations made by the speaker lead him to believe that the anterior margin of the foramen magnum is not more than three and a half or four inches from the external wound. Nevertheless all these symptoms could not have been caused by the penetration of the rod into the nervous tissue. In the cadaver the anterior margin of the foramen magnum corresponds with the lower portion of the olivary body, and a single lesion at this point would not account for all of the symptoms, while an extensive injury here would have led to an immediately fatal termination. Perhaps in some way a blood-vessel may have been occluded, and thus an area of softening in the above-mentioned part was produced.

The prognosis is not altogether favorable. The increase in the anæsthesia, the recent development of diabetes, and the increased feebleness in the paralyzed side seem to indicate a progressive process, and but slight extension of the lesion in a part of such vital importance might speedily produce a fatal issue.

Accouchement by Firearms.—Dr. Granier, surgeon in the French army, writes from Algeria: "A few days after the occupation of Brizerte, when the military authorities had forbidden, under the severest penalties, the discharge of firearms within the town, the whole garrison was awakened at three o'clock one morning by the tremendous explosion of a heavily loaded gun in the neighborhood of the ramparts; a guard of soldiers rushed into the house from whence the sound had come, and found a woman lying on the floor, with a newly born babe between her thighs. The father of the child stood over his wife with the smoking musket still in his hand, but his intentions in firing the gun had been wholly medical, and not hostile to the French troops. The husband discovered that his wife had been in labor for thirty-six hours. Labor was slow and the contractions weak and far apart. He had thought it advisable to provoke speedy contraction, and, following the Algerian custom to *scare the baby* out, he had fired the musket near his wife's ear; instantaneously the accouchement was terminated. After being imprisoned twenty-four hours the Arab was released."—*Cincinnati Lancet*, August 1, 1885.

SUCCESSFUL CASES OF PULMONARY PHTHISIS.

By W. H. GEDDINGS, M.D,

Aiken, S. C.

(Continued from page 374.)

Case XIX. *Infiltration of right lung; recovery.*—A young married lady; my own case; family consumptive. Four weeks she has had cough, with severe pleuritic pain on the right side. Has had more or less fever, with perspirations at night.

January 11, 1880.—Pulse, 104; temperature, 99°. Pale and quite delicate in appearance. Diminished resonance over the upper portion of the right lung in front, with dulness over scapular and interscapular spaces. Respiration bronchial, with prolonged experium.

April 6th.—Is greatly improved, and has been able to resume her rather arduous duties of housekeeper of a large boarding-house. Still coughs a little. Can detect no dulness in front, but it is still apparent over the suprascapular and corresponding interscapular regions. At the time of writing (1885) this patient remains in perfect health and has no cough.

Case XX. *Infiltration of upper portion of right lung, hemorrhages; recovery.*—Male, thirty-four years of age. (Dr. Riggin Buckler, of Baltimore, Md.) No hereditary predisposition to consumption. Disease began with a slight hemorrhage in February, 1880. Has had several since then, and has lost four pounds. Came to Aiken in November, grew better, and went to Gainesville, Fla., where he improved at first, but subsequently lost ground.

March 3, 1881.—Pulse, 68; temperature, 97.5°; pale, with slender figure; weight, 147½ pounds; appetite poor, but with good digestion. Has cough, and expectorates one half ounce of muco-purulent matter. Can walk two miles without feeling fatigued. On the right side, dulness from the clavicle to the third rib and over the suprascapular region; also over the axillary region. Auscultation affords no evidence of disease other than occasional rhonchi, except over the interscapular space, where it is distinctly bronchial.

April 5th.—With the exception of slight hæmoptysis, a few days after his arrival, he has steadily improved. Pulse, 72; temperature, 98.5°; weight, 155½ pounds—a gain of eight pounds. Appetite has improved and the digestion is good. Can now walk six miles without being tired. No change in the condition of the diseased lung in front, but behind and in the axilla the dulness is less marked. He remained a couple of weeks longer in Aiken, suffered with the heat, and lost one and three-fourths pound of what he had gained. Dr. Buckler wrote me a year later (February 18, 1882) that his patient had grown so stout that his friends could scarcely recognize him, and that, with the exception of being a little short-winded he was apparently quite well.

Case XXI. *Infiltration of right apex, hemorrhages, night-sweats; recovery.*—A young man, twenty-one years of age, from Pittsburg, Pa., a patient of Dr. Fundenburg, of the same place. Was also examined by Dr. Da Costa, of Philadelphia. Family record good. Cough began in July, 1881; had night-sweats, and lost twenty pounds.

November 1, 1881.—Patient is slender, complexion sallow, finger nails clawed. Cannot walk a quarter of a mile without being fatigued. Pulse, 92: temperature, 98.2°. Cough moderate, with one-half ounce of muco-purulent expectoration. On the right side there is dulness, extending in front from the clavicle to third rib, and posteriorly to one inch below the spine of the scapula, with diminished resonance in the axillary region. The respiration on the same side is bronchial, with prolonged experium.

During the first month of his stay in Aiken he grew steadily worse, his temperature rising at times to 102°, but about the middle of December he began to improve,

and, with the exception of a slight hemorrhage in January, did well until April 10th. His cough and expectoration ceased, and he gained six pounds. He passed the summer at Bethlehem, N. H., and in the fall made a voyage to England, doing well all the while. Returning to Aiken in November, 1882, he again improved. In the summer of that year he went to Bismarck, Dak., and held his own until December 30th, when he again returned to Aiken for the third time. When last seen (1885) there had been no return of cough, and the only evidence of disease was slight dulness at the apex of the right lung. He has since written to me that he has remained quite well.

Case XXII. *Extensive disease of right lung, hemorrhage, profuse expectoration; arrest.*—A young machinist of Boston, twenty-four years of age, a patient of Dr. McDonald, of that place. Had acute pneumonia in 1875, followed by cough, which, after ceasing for a time, returned in the fall of 1880, and has persisted ever since. One sister died of phthisis. Has had only one hemorrhage, but the sputa have been tinged with blood. Has lost ten pounds.

November 14, 1881.—Pulse, 100; temperature, 99.5°; weighs 143½ pounds. Cough troublesome, with about eight ounces of muco-purulent expectoration in twenty-four hours. On the right side there is dulness in front, from the clavicle to the fourth rib; behind diminished resonance over the upper third of the shoulder-blade. The respiratory murmur on that side is feeble, with prolonged experium.

January 17, 1882.—Much improved in appearance. Pulse, 80; temperature, 99.2°; weight, 148¾ pounds, a gain of five and one-half pounds. Coughs but little; expectoration is reduced from eight ounces to one ounce a day. The area of dulness has receded to the second rib. This patient did so well that he did not deem it necessary to consult me again. He continued to improve and is now (1885) settled on a farm in Florida, where he is reported to be in the best of health.

Case XXIII. *Infiltration of right lung; recovery.*—A clergyman, thirty years of age, of Concord, Mass.; patient of Dr. Emerson of the same place. Hereditary tendency to phthisis, great-grandfather, grandfather, and one brother have died of phthisis; also several cousins. Resembles father. Has had tinged sputa, but no hemorrhages. Has lost eight pounds. Has occasional chills, followed by fever. Disease began with bronchial catarrh in January, 1881.

August 18th.—Pulse, 88; temperature, 98.7°. Has slight cough, with two and one-half drachms of muco-purulent expectoration. On the right side there is diminished resonance in front over supraclavicular space, with dulness from thence downward to third rib. Posteriorly dulness from apex to within two inches of the angle of the scapula. Respiratory murmur, both front and back, is feeble, with prolonged experium. Patient improved during his stay at Bethlehem, passed the winter on Moosehead Lake, Me., where he gained rapidly. He afterward removed to Cordova, in the Argentine Republic, where he completed his cure. In a letter from him in 1884, he represented himself as quite well, and was anxious to return to the United States.

Case XXIV. *Extensive disease of right lung, hemorrhage, emaciation, etc.; complete arrest.*—Male, thirty years of age, Cincinnati; patient of Dr. Hunt, of Covington, O. Disease began in the spring of 1881 with fever and cough, followed by hæmoptysis in October of the same year. Has lost thirty-one pounds.

December 17, 1881.—Pale and slender, nails clawed; pulse, 96; temperature, 99.6°; weight, 114 pounds. Is so weak that a walk of half a mile causes great fatigue. Has cough, with about one drachm's expectoration. Right front dull from clavicle to fourth rib, and behind from the spine of the shoulder-blade to its angle. Respiration feeble and indistinct.

May 9, 1882.—Patient has steadily improved. Pulse and temperature are normal; weight, 133½ pounds—a gain of nineteen pounds. Walks five miles without the slightest fatigue. Has neither cough nor expectoration. All physical signs of disease have disappeared. Has not been heard from since his return home.

Case XXV. *Infiltration of upper portion of right lung, night-sweats, etc.; arrest.*—December 9, 1881.—A young lady from Quebec, a patient of Dr. C. Sewell, of the same place. Strong hereditary predisposition to phthisis—one uncle, two brothers, and a sister having died of that disease. Has had persistent cough, with occasional night-sweats, since June, 1881. Pulse, 76; temperature, 99.5°; appetite poor, with more or less dyspepsia. Cough troublesome, with one drachm of expectoration. Weight, 136½ pounds. On the right side, dulness from clavicle to second rib in front, and over supraspinous fossa behind. Respiratory murmur feeble, with warm, moist râles.

January 10, 1882.—Pulse, 86; temperature, 99.8°; weight, 140 pounds—a gain of three and a half pounds. Appetite and digestion quite good. Cough much improved. The dulness has disappeared from the back, but is still quite perceptible in front. When last heard from this patient was quite well, but deemed it prudent to pass her winters at Bournemouth, England.

Case XXVI. *Infiltration of right apex, profuse hemorrhages, arrest for two years, relapse, and subsequent recovery.*—January 2, 1882.—A lawyer from Wellesly, Mass., thirty-four years of age; patient of Dr. A. Hosmer, of Watertown, Mass. Hereditary predisposition to phthisis. This patient came to Aiken several years ago with marked disease of the right apex; had several hemorrhages, but made a good recovery and remained well for two years. In 1876 he had a return of the hemorrhages, but again improved. The same thing occurred in August, 1881. Complexion fair, nails clawed; pulse, 80; temperature, 99.5°; cough, moderate. Right side dull in front from clavicle to second rib, and behind over the scapula, extending one inch below the spine of that bone. Bronchial respiration, with prolonged expiratory murmur.

March 27th.—Has improved steadily. Pulse and temperature normal; has but little cough. Dulness persists in front, but posteriorly there is only slightly diminished resonance over the supraspinous fossa. He presents the appearance of a person in robust health. Subsequently he removed to Florida, where, at last accounts, he was still living in the enjoyment of almost perfect health.

Case XXVII. *Infiltration of right apex, hemorrhages, night-sweats, etc.; recovery.*—A gentleman, forty-eight years of age; patient of Dr. J. M. Da Costa, of Philadelphia. One brother died of chronic pneumonia. Disease commenced with an attack of hæmoptysis in July, 1881, followed by cough and night-sweats.

January 21, 1882.—Tall and slender, complexion sallow. Pulse, 72; temperature, 98°; weight, 154 pounds. Has slight cough without expectoration, good appetite, and fair digestion. On the right side there is an area of dulness extending in front from the clavicle to fourth rib, and to one inch below the spine of the scapula; behind, marked prolongation of expiratory murmur.

March 23d.—Greatly improved, having gained five pounds in two months. Pulse, 57; temperature, 97.8°. Has scarcely any cough, and is apparently quite well. The area of dulness in front has receded to second rib, posteriorly it remains unchanged. Patient has continued to improve, and at last accounts was doing well.

Case XXVIII. *Infiltration of left apex, night-sweats, with emaciation; recovery.*—A little girl, ten years of age; patient of Dr. Minot, of Boston, had capillary bronchitis in January, 1882 and has coughed ever since; has had night-sweats and has lost from five to ten pounds.

March 4th.—Pulse, 100; temperature, 99.4°; has a good appetite, and can walk a mile without being fatigued. Has a little dry cough. There is a small area of dulness

under the third rib, near its junction with the sternum. Posteriorly there is dulness from the angles of the scapula to the base of the lung. Respiration rough, with prolonged experium.

May 6th.—Much improved. Pulse, 84; temperature, 99°. Has still slight cough, but in other respects appears to be in perfect health. The dulness is still perceptible in front, but over the back it is confined to a narrow strip at the base of lung. During the summer she was examined by a leading specialist in Boston, who declared that he could detect no dulness. She has remained quite well ever since.

Case XXIX. *Infiltration of the upper portion of the right lung, profuse hemorrhages, night-sweats; recovery, with a gain of forty pounds.*—A young Charlestonian, twenty-one years of age; patient of Dr. J. F. M. Geddings, of Charleston, S. C. Both paternal grandparents died of phthisis, and his father had hemorrhages when a young man, but is now quite robust and in perfect health. In 1880 he had hemorrhages, followed by fever, cough, and emaciation, but recovered, and remained quite well until April 29, 1882, when he had another attack of bleeding.

May 16th.—He has lost twenty-five pounds, is pale, has moderate cough with a small amount of expectoration. Pulse, 100; temperature, 99.5°; weight, 153¾ pounds. Over the right lung there is dulness in front from clavicle to third rib, and posteriorly a more extensive area of dulness extending from the apex to within an inch and a half of the angle of the scapula. Respiratory murmur feeble, with prolongation of the experium. He improved rapidly, lost his cough, and was so well that he indulged in dancing and rowing with impunity. He remained in good condition until the end of July, when he brought on a severe attack of hæmoptysis by climbing Lannon Mountain from the Profile House, from which the ascent is very precipitous. He rallied from this attack, but had a recurrence of the hemorrhage in the fall, this time bleeding at times quite profusely—as much as three pints in as many days and necessitating the constant application of ice. Since then he has steadily improved, and at the present date (January, 1885) is perfectly well and is pursuing his studies as a medical student. His pulse and temperature are normal; he has had no cough for over a year, and has gained forty pounds in weight. The only evidence of disease is a limited area of dulness at the apex and over a small portion of the interscapular space.

Case XXX. *Disease of right apex, hemorrhages, and emaciation; arrest.*—A Wall-street broker, thirty years of age, a patient of Dr. A. L. Loomis, of New York. Disease commenced with bronchial catarrh in October, 1882. During that month he had five profuse hemorrhages, bleeding at one time as much as twelve ounces. Has lost nineteen pounds.

December 13th.—Pale and slender, nails clawed. Pulse, 100; temperature, 99.3°; weight, 142¼ pounds. Cough troublesome, with about two and a half ounces of expectoration. In front there is dulness on the right side, extending from the clavicle to the third rib, and behind from the apex two inches below the spine of the scapula. Expiratory murmur is prolonged; other respiratory symptoms not noted. He improved rapidly, and by the 7th of March, 1883, had gained fourteen pounds, and for two and a half months has been entirely free from cough.

April 3d.—Looks quite robust. Pulse, 80; temperature, 98.3°. The warm weather of spring has brought on a slight attack of gastric catarrh, causing him to lose one and a half pound of the fourteen gained during the winter. There is no dulness in front, and only a small patch of diminished resonance behind. This patient has not been heard from.

Case XXXI. *Infiltration of right apex; recovery.*—A lady from Albany, N. Y., thirty-eight years of age; patient of Dr. W. H. Draper, of New York. Comes of a phthisical family; maternal grandmother, a brother, and a sister having all died of consumption. The father had "weak lungs" when young, but recovered, and is now quite well. She had persistent cough in 1878, but recovered and remained well until April, 1882, at which time the cough returned and has been present ever since.

December 19, 1882.—The patient is a frail-looking woman, with pale complexion. Has a fair appetite, but her digestion is much impaired. Weight, 103½ pounds. Has cough, with a moderate amount of expectoration, all of which floats. There are evidences of dulness over the upper portion of the right lung extending in front to the fourth rib, and posteriorly half-way down the scapula, the expiratory murmur being feeble and jerking.

April 21st.—Notwithstanding repeated attacks of dyspepsia patient has improved, and has gained six and a half pounds in weight. Has only slight cough. The front is resonant, and the only evidence of disease is a small area of dulness over the middle of the interscapular space. She has been under my observation ever since, and is now quite recovered, having had no cough, except from an occasional cold, for over a year.

Case XXXII. *Infiltration of left apex, night-sweats, emaciation, etc.; recovery.*—Male, aged twenty-seven; patient of Dr. Fassett, of St. Alban's, Vt. Has had occasional cough since 1875; persistent since August, 1882. Has lost twenty-eight pounds.

January 18, 1883.—Complexion clear: figure slender; rather frail looking, with flabby muscles. Pulse, 100; temperature, 99.5°; weight, 140 pounds. Suffers with night-sweats. Has moderate cough, and expectorates about six ounces of muco-purulent matter, all of which floats. On the left side there is marked dulness from clavicle to second rib and over the supraspinous fossa, with feeble respiratory murmur.

April 9th.—Pulse, 84; temperature, 99.7°; weight, 150 pounds—a gain of ten pounds. Is much improved in strength, has but little cough, and only one and one-half ounce expectoration. The only physical signs of disease are, an area of diminished resonance over the supraspinous fossa, and feebleness of the respiratory murmur. A report received from Dr. Fassett, a year later, represented the patient as quite well, and stated that he had resumed his business.

Case XXXIII. *Infiltration of upper third of right lung, resulting from acute pneumonia, night-sweats and emaciation; complete recovery.*—An Englishman, aged thirty-two, from Perthshire, a patient of Dr. Sloman, Surrey, England.

On December 14, 1882, he was seized with a severe chill, followed by fever, cough, and rusty expectoration.

February 3, 1883.—A blond, slender figure, and well built, with firm flesh. Pulse, 72; temperature, 98.5°; weight, 137¾ pounds. On the right side there is dulness extending in front from the clavicle to fourth rib, and posteriorly to the middle third of the scapula, with feeble respiratory murmur. Appetite not very good; digestion fair. Has night-sweats.

April 3d.—Has improved steadily. Pulse and temperature have remained normal; has gained seven and three-quarter pounds. There is no trace of dulness, and the respiratory murmur is vesicular on both sides.

Case XXXIV. *Infiltration of right apex, with fever, night-sweats, and emaciation; recovery.*—A medical student, aged twenty-three, from Whitestown, Oneida County; a patient of Dr. Janeway, of New York. Disease began with bronchial catarrh in the autumn of 1881. Had cough and night-sweats, with emaciation to the extent of ten pounds. Expectoration has been at times tinged with blood.

February 12, 1883.—Slender figure, with sallow complexion. Pulse, 100; temperature, 101.5°; weight, 114 pounds. Appetite poor, but with fair digestion. Cough troublesome, with one-half ounce of expectoration. Over the right front dull from clavicle to fourth rib, posteriorly from the apex to one inch below the scapula. Respiratory murmur feeble.

May 10th.—Much improved. Has gained seven and one-quarter pounds. Coughs but little, and does not expectorate more than two teaspoonfuls in twenty-four hours.

He continued to improve during the summer, and also during the following winter. When last examined the dulness had disappeared from the front, except over a limited area beneath the clavicle and over the interscapular space.

Reports received this winter (1885) inform me that he is quite well, and that he is engaged in business in Syracuse as a drug clerk.

Case XXXV. *Disease of the apex of the right lung; recovery.*—A young German, from New York, twenty-five years of age. The disease began with bronchial catarrh in 1875, followed by several slight hemorrhages. Spent the summer on Schooley's Mountain, N. J., where he lost his cough, and returned to New York, to all appearances quite well. There, by the advice of his physician—an eminent specialist in pulmonary affections—he resumed his business, but was soon again compelled to relinquish it on account of a return of the old symptoms. He was then sent to the Adirondacks, where he again improved, but finding himself ill on his return to New York, he started for Europe, where he was treated successively at Falkenstein (Dr. Detweiler), at Davos, and at Mesan (Dr. Pircher). The patient has passed the whole winter at Aiken, but has done so well that he has not required medical advice.

May 13th.—Pulse, 88; temperature, 99¾°; looks well, and has a good, healthy color. Has increased in weight. At all the other resorts he has frequented the sputa have been more or less tinged with blood; but since his arrival in Aiken there has been no trace of bleeding. He expands the chest to the extent of three inches without any great effort. Dulness quite pronounced under and below the right clavicle; in the axillary line the percussion sound is short. On the back of the same side there is also dulness under the superspinous fossa. Auscultation reveals bronchial respiration over the left apex, with prolonged expiration in the axillary region. Mucous râles, formerly observed by Dr. Pircher, under the upper portion of the scapula, have all disappeared. This patient is now (1885) established in Switzerland, and is in perfect health.

Case XXXVI. *Extensive infiltration of the upper third of left lung, large cavity, repeated hemorrhages, emaciation; recovery.*—A Spanish merchant, native of Barcelona, but for several years a resident of Charleston, S. C., and a patient of Dr. Bellinger, of that city. He is thirty years of age, and has no hereditary predisposition to phthisis. Disease began with bronchial catarrh in May, 1881. Has had several moderate hemorrhages, during one of which coughed up a well-defined cast of a portion of the bronchial tubes.[1] Has lost eleven pounds.

November 3, 1882.—Patient is tall and slender, with dark, sallow complexion. Nails characteristically clawed. Pulse, 112; temperature, 99.8°; weight, 138¾ pounds. Patient has a very poor appetite, and suffers with indigestion. Cough is very troublesome, with muco-purulent expectoration, a portion of which sinks if expectorated into water.

Over the left front there is distinct dulness from the clavicle to the fourth rib, with an area of tympanitic resonance over the third rib. Over the back there is also dulness extending from the apex to two inches below the spine of the scapula. Over this space there is cavernous respiration, with pectoriloquy in front and moist râles posteriorly.

April 13th.—Patient rapidly regained his appetite and strength, and notwithstanding his having had a severe diarrhœa and several attacks of rheumatism, is much improved. He is much stronger, and sometimes walks six miles without experiencing any fatigue. Pulse, 92; temperature, 98.8°. The extent of the infiltration remains unchanged, and the evidences of cavity are still present. On leaving Aiken, he returned to his home in Barcelona, where he continued to improve, and at last accounts (1884) was quite well.

Case XXXVII. *Infiltration of the upper portion of left lung.*—A young man from Burlington, Vt., the name of whose physician I failed to note, presented himself at my office, 1877, with history of cough, emaciation, etc., extending over several months. Temperature, 100.6°; cough troublesome. Physical examination revealed a slight area of dulness over the left subclavicular region and under the scapula.

April 22d.—During the winter he had a slight hemorrhage, but is now much improved in general appearance and coughs less. Temperature, 99.2°. Has increased five pounds in weight. Dulness in front unchanged, but behind it does not extend more than one inch below the spine of the scapula.

He returned to Aiken the following winter, but was so well that he did not present himself for examination. In the summer of 1884 he called on me in Bethlehem, N. H., and reported that he had had no further trouble since his departure from Aiken in 1878. He was then (1884) in robust health.

Case XXXVIII. *Repeated hemorrhages, night-sweats, emaciation, infiltration of right lung with cavity.*—Male, thirty-three years of age; patient of Dr. James W. White, of Philadelphia. Maternal grandmother, mother, and maternal uncle died of phthisis. No marked resemblance to either parent. Disease began with an attack of hæmoptysis on October 5, 1882. Visited the Bermudas, but grew worse while there. Has lost twenty pounds.

December 24, 1883.—The patient, who is of medium size and well built, is rather pale, with clawed finger-nails. Pulse, 88; temperature, 100.5°; weight, 138½ pounds. Appetite and digestion good. Cough moderate, with two ounces of muco-purulent expectoration. Suffers with night-sweats. Over the right front there is marked dulness from the clavicle to the fifth rib, with diminished resonance from that point to the base. Below the clavicle there is pectoriloquy and cavernous respiration. Posteriorly there is a corresponding area of dulness extending to the angle of the scapula, with slight dampening of the percussion sound over the lower half of the lung. Respiratory murmur feeble, with increased vocal resonance. There is, also, dulness over the axillary region.

April 8, 1884.—With the exception of a slight hemorrhage, the patient has steadily improved. Pulse, 80; temperature, 99°; weight, 144½ pounds. Sweats have ceased. Cough persists, but the expectoration is reduced to one ounce. The lower border of the dulness anteriorly has receded to the third rib, the lower portion of the lung having recovered its normal resonance. Posteriorly there has been no change in the physical symptoms.

April 28, 1885.—Patient remained quite well during the summer, returned to Aiken in the fall, and has continued to improve throughout the winter. His face is full and ruddy, his limbs well rounded; his general appearance being that of a person in the most robust health. He walks nine miles without experiencing the slightest fatigue; going out day and night in the worst weather with perfect impunity. During the past year he has not had a single day's illness. He still coughs a little, but there has been a steady diminution in the extent of the infiltration. In front the dulness remains unchanged, but behind the only evidence of disease is slightly diminished resonance over the upper half of the scapula.

Conclusions.—In summing up the above the reader will be struck with the great preponderance of cases in which the disease was located in the right lung. Including the three cases in which both lungs were implicated the right lung was affected in thirty, and the left in only

eleven instances. I have not had time to ascertain whether this accords with the experience of other observers, but even without this confirmation the large number of cases extending over five or six years would appear to establish the fact that the disease, when located in the right lung, affords a much more favorable prognosis than when the left is the seat of the disease. The question of heredity was lost sight of in many of these cases, but in those in which it was noted there was evidence of hereditary transmission in thirteen out of seventeen.

The average age of the above cases when they came under treatment was twenty-nine years. Three were children under ten, two of whom made perfect recoveries, while one relapsed, after having enjoyed good health for over a year, and is still under observation, but is doing well. It is worthy of remark that these were the only children among several hundred phthisical patients treated, and the fact that recovery took place in every case is a striking confirmation of the now generally received opinion that the prognosis of phthisis in children under ten years of age is much more favorable than at any other period of life.

Hemorrhages occurred in twenty-two cases, *i.e.*, in two-thirds of the whole number.

Cavities were observed in only three cases, proving conclusively that recovery is rare after softening has begun.

The fact that twenty-nine males recovered, and only nine females, is somewhat remarkable. It is true that more males than females visit health resorts, but this fails to account for the great disparity in the general result, and forces upon us the conclusion that the disease is much more fatal among women than among men.

It is but fair to state that the above cases include only a small proportion of those who have recovered at Aiken. Many were treated by my colleagues, who doubtless obtained equally good results, but a still larger proportion, I am convinced, recovered without medical aid. These comprise cases of incipient phthisis, in which change of climate alone effects such marked improvement that they deem it unnecessary to invoke medical aid. Although successful in many cases this is a course which no physician of experience would advise an invalid to adopt. In a chronic disease, especially in consumption, the patient is over-sanguine, and is only too ready to emancipate himself from medical control, and, if left to his own guidance, will often by imprudence and neglect undo the work of years. The consumptive may at times need no drug treatment, but he is always the better for judicious medical supervision. He should always be made to realize that arrest does not necessarily imply a cure, and where it is possible I always insist upon the patient's remaining under supervision for at least two years after all signs of active disease have disappeared.

Rearing Premature Infants.—Professor Tarnier presented at the Académie de Médecine two children, born at the sixth month, whom he had succeeded in rearing by the aid of the couveuse, and forcible feeding with woman's milk. Two drachms of milk were injected through a caoutchouc tube into the stomach every hour for the first three days, and then four drachms were injected every three hours. It is necessary to begin with small quantities, or the child becomes swollen by an acute œdema through hypernutrition. The couveuse is used at a temperature of 86° to 98° F. The younger the infant the higher the temperature employed. Dr. Blot observed that he regarded the couveuse as a useless procedure, as the same results are attainable by the employment of cotton and bottles of hot water. M. Tarnier said that during the employment of the couveuse he had on several occasions been astonished at the rapid disappearance of the sclerema of infants.—*Medical Times and Gazette.*

THE ACTION OF HYDROBROMATE OF HYOSCIN.

By ARCHIBALD CHURCH, M.D.,

NORTHERN ILLINOIS HOSPITAL FOR INSANE, ELGIN, ILL.

From some little experience with hydrobromate of hyoscin upon the insane, I would like to offer a few words in regard to it, as it has been brought prominently forward by the valuable article of Drs. Peterson and Langdon, in The Record of September 19th.

To the conclusions arrived at by them agreement in a general manner must be accorded, but it seems that the drug has more usefulness than they would indicate. In sthenic acute conditions, or violent manifestations arising in the course of chronic insanity, it has notably and promptly lessened the excitement, and in the frenzy of melancholia has mitigated the outbreak in cases where it has been tried in this hospital. While not doubting that its continued administration in small and often repeated doses will disarrange alimentation—and what powerful drug does not?—it has yet rendered signal service in tolerably full doses, $\frac{1}{40}$ grain, given when specially indicated, without producing any untoward symptoms whatever. By watching its action upon others, and upon myself, in varying doses, it did not seem advisable to give it in a more routine manner than one does morphia or atropia in parallel cases, and, so far, more than two doses of $\frac{1}{40}$ grain have not been used in twenty-four hours.

By careful sphygmographic observations it is clearly shown that minute doses—$\frac{1}{150}$ to $\frac{1}{100}$ grain—of the hydrobromate are stimulant of cardiac action, and thereby of the mental processes and attendant manifestations, not only among the insane, but in a condition of health. With a larger dose—$\frac{1}{40}$ to $\frac{1}{20}$ grain—this also is the primary result, but as more of the medicament comes into operation it is followed by a slowing of the pulse-rate and by a diminution of the cardiac curve of the tracing, sometimes to such an extent that a bruit of dicrotism appears. A feeling of fatigue, or rather of comfortable weariness, if you will permit such a term, is now associated, and one gives up readily to feelings of drowsiness, sleep following naturally. After using the drug in $\frac{1}{40}$ grain doses for from six to ten consecutive nights, with an average of six hours' sleep, for instance, its discontinuance has been followed, but only after several nights, by wakefulness, which again gave way to the remedy. In some instances of confirmed insomnia, or rather of often-disturbed sleep, after securing a few nights' good rest the patient has rested fairly well, the habit of waking at certain times being broken, and in general the effect of the drug is lasting. When given by the mouth, as was pointed out in the article above referred to, its action is slow and there is considerable variability as to the amount required by different patients. Although no notable depression has come under observation from the use of the drug in such doses as are indicated above, it no doubt is capable of producing stupor just as does hyoscyamia, which doubtless in the amorphous form contains it largely, but which is associated with little danger, according to a recent writer in the London *Lancet*, who gave unhesitatingly $\frac{1}{2}$ grain, and even $\frac{3}{4}$ grain of Merck's preparation, producing coma, etc.

It may be not uninteresting to note that hyoscin is a very active mydriatic. It was found that two drops of a solution one-tenth grain to the ounce of distilled water produced complete dilatation of the pupil and paralysis of the accommodatory muscles in about five minutes, and that it was more active to stretch the adhesions in a case of posterior synechia than the repeated instillation of a solution of atropia sulphatis three grains to the ounce. The mydriasis so produced is very persistent, lasting from five to ten days, and the use of the solution is not attended, as far as observed, with any conjunctival irritation, which will suggest its value to oculists where the long-continued action of a mydriatic is required.

From the little learned concerning the drug it would seem to be of use in conditions of intensified nerve action, especially of cerebral origin, to meet acute manifestations.

A SCHEMATIC EYE FOR STUDENTS OF OPHTHALMOSCOPY.

By J. B. EMERSON, M.D.,

ASSISTANT SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL; INSTRUCTOR IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

THE most difficult part of ophthalmoscopy for the student to master is refraction, and as a good knowledge of this can only be attained by long-continued and careful practice, many students are deficient in it through lack of time and suitable subjects for examination. Again, in examining the fundus of an eye, from not having an object of known size for comparison, they often think that they see objects *distinctly* which should not be distinctly seen under the conditions. The reason of this is, that beginners in ophthalmoscopy are apt to focus on large objects, such as the optic nerve or the large blood-vessels, instead of the smaller branches of the vessels. In order to assist those who desire to perfect themselves in this branch of ophthalmology, I have arranged an instrument which may be called the student's schematic eye, and which differs in some respects from those now in use.

It consists of a tube 2½ inches in length and 1⅛ inch in diameter, attached by a hinge to a vertical rod, which rests on a stand and can be raised or lowered at will. In one end of this tube is a convex lens of 3 inches (13 D.) focal distance, which represents the refractive media of the eye. Just behind this is a perforated diaphragm of leather, which represents the iris and pupil. Telescoped in the other end of the tube is a second tube, 2¼ inches in length, which is moved in or out by means of a pin and ratchet. At the remote end of the second tube is a disk of metal which represents the retina, and on it is placed a card, in the centre of which is a circle of $\frac{1}{10}$ inch diameter, with two lines crossing the centre at right angles to each other. In the space about the lines are photographed sentences, the letters of which are too small to be distinguished without a magnifying-glass (about one-half size of No. 1 Jaeger). If we place this disk at 3 inches from the lens, we have the condition of an emmetropic eye: if it is moved nearer we have hypermetropia; if further, myopia. The inner tube is graduated to show the degree of each.

In order to produce the condition of astigmatism a convex lens of 3 inches focal distance, on which has been ground a cylindric lens of 30 inches focal distance, is substituted for the original lens; and by adjusting the inner tube nearer them, or beyond the focal distance, the various forms of astigmatism are produced.

This instrument can be made useful in three ways:

1. For teaching the direct method of ophthalmoscopic examination. A light and mirror are then used as in examining the human eye. When the tube is adjusted at 0 it will be impossible to read the words on the disk unless the accommodation of the eye of the examiner is fully relaxed. By shortening the distance it can be read with glasses that correct the permetropia. If the distance is increased it will require, to read the letter, a concave glass which corrects the myopia. By substituting the astigmatic lens the circle appears elliptical, and the vertical, or horizontal lines will be distinct or blurred as the axis or disk is changed from one position to another. By using the indirect method of examination it can be clearly demonstrated that the fundus is inverted.

2. For the practice of retinoscopy, or the shadow test. To do this a ring is placed on the front of the tube, with grooves for holding two trial lenses.

3. For demonstrating the principles of refraction. In this case a disk of ground glass is substituted for the metallic disk, and by observing the images formed on it by distant objects, emmetropia, hypermetropia, myopia, and astigmatism, with the effects of their respective correcting lenses, can be clearly shown. By observing the images of near objects, the effects of accommodation are also demonstrated. I have been assisted in perfecting this apparatus by my fellow, Dr. George T. Ball. It may be procured of Meyrowitz Brothers.

Clinical Department.

MAGGOTS IN THE HEAD.

DR. C. M. HARRISON, of Del Rio, Tex., writes that the presence of worms in the cavities of the head, reports of two cases of which he had seen some time ago in THE MEDICAL RECORD, is by no means a very uncommon phenomenon in that country. There are two species of flies which attack diseased parts, viz., the blue-bottle (*musca vomitoria*), and the flesh-fly (*sarcophaga camaria*, Meg). The blue-bottle deposits eggs, which are hatched in two or three hours provided they are kept moist and warm; and the flesh-fly deposits living larvæ, which commence to burrow at once. It was of the latter kind Linnæus said that the larvæ of three females would devour the carcass of a horse as quickly as would a lion. These are popularly known as "screw-worms," and they increase in size with amazing rapidity. The flies deposit their eggs or larvæ in decomposing substances, and it is probably, the writer says, because there is so little decaying animal matter in his country, owing to the dry air, that the flies so often attack diseased tissues in the living subject. Dr. Harrison writes: "The first person I ever treated for larvæ in the nose was a Mexican, a shepherd, about forty years of age, who had nasal catarrh. I visited him one morning and found him apparently unconcerned, partly because he was suffering but little pain at the time, and partly, also, because he had cured and seen cured so many cases of screw-worms in sheep. I immediately injected into the nares a solution of carbolic acid in glycerine and water, syringing the cavity well, and bringing away eight or ten wriggling maggots. I then hoped I had reached them all, but was disappointed, on returning a few hours later, to find my patient suffering considerable pain, with a bloody serum running from his nose. I then changed solutions, resorting to corrosive sublimate, turpentine, tannin, and morphine, using each in turn, but always finding that I had failed to dislodge all the worms. I used first one solution and then another, through the anterior and then the posterior nares, but despite all my efforts the patient died in agony at the end of three days. His features were unrecognizable. The eyes were swollen and closed, and the face was puffed out to a level with the nose, while from the nares a bloody serum was constantly flowing.

"About two months later I was called to see another case in the same house. The patient was a Mexican woman, forty-two years of age. This time, after failing to accomplish much with my injections, I secured consultation, but only succeeded in obtaining companions in my misery. Finally, at the end of the second day, we became desperate and resolved to see what could be accomplished by cutting into the nasal cavities. We found it necessary to keep the woman in nearly a sitting position, in order to prevent the serum, which was constantly

oozing, from running down the throat. The woman had hardly begun to inhale the chloroform when down tumbled a stupefied maggot, fully half an inch long. We thus succeeded in grasping a number with the forceps, and the patient, not yet being fully anæsthetized, felt them coming down through the posterior nares, and as she did so would hawk and roll them forward with her tongue and spit them out. By putting a cork between the molars and using a tongue-depressor we were able, after she became unconscious, to reach into the throat and seize the stupefied worms as they came down. In this way we removed sixty-seven worms. I then used antiseptic and soothing injections, and hoped the trouble was at an end. But my disappointment was great, on returning the next day, to find the patient with both eyes closed by the swelling, picking away an occasional live worm, and suffering severe pain. Becoming desperate, I mixed a half-ounce of pure chloroform with an equal amount of the antiseptic solution, and threw the whole with considerable force into the anterior nares. The woman gave a groan and fell over as though dead, and I waited with some anxiety to learn whether I had killed my patient or the worms. But the woman recovered, and from that time no more live worms were seen. But dead ones innumerable came away in knots of from three to ten for three days, each time that I syringed out the cavity. The woman is alive, but her nose is completely hollowed out and sunken in at the sides, for the septum and turbinated bones have disappeared. Since that time I have always treated the cases in this way, using chloroform first to kill the maggots."

Dr. Harrison relates another case, of maggots impacted in the external auditory canal. There was so much swelling about the entrance that no injections could be used, but by blowing in the fumes of chloroform the worms were killed. Soothing applications were made until the swelling was reduced, and the dead maggots were then syringed away.

[In the case of the woman who recovered with loss of the septum and turbinated bones, we would venture the suggestion that this was the result of pre-existing syphilitic disease. The fetor of syphilitic necrosis would be likely to attract the flies, who would deposit their eggs or larvæ in the nostrils, and the maggots might then complete the destruction of the soft parts. But it is hardly to be supposed that worms could in so short a time eat away and completely destroy the bone tissue.—Ed.]

FIBROID TUMOR OF THE MIDDLE EAR—NEURALGIC PAINS, OTORRHŒA, AND DEAFNESS—REMOVAL OF TUMOR FOLLOWED BY RESTORATION OF FUNCTION.

Dr. C. W. Trueheart, of Galveston, Tex., reported the following case at the meeting of the Texas Medical Association: Laura O——, fifteen years of age, had been subject for over five years, with occasional intermissions, to deep-seated pain and distressing tinnitus in the left ear, accompanied with deafness and a slight discharge. The girl had acquired the faulty articulation, listless manner, and vacant expression of countenance induced by long-continued deafness in the young. On the left side she could hear the watch only when it was firmly pressed against the ear, and the ordinary voice at a distance of two feet. The tuning-fork placed against the head was heard with very slightly more distinctness on the left side than on the right. The Eustachian tube was completely closed. The drum membrane was of a dusky red color, somewhat thickened and irregularly sunken, with a perforation the size of a large pin-head, through which pus was oozing, a little behind the handle of the malleus. On the right side the watch was heard at two inches, and the voice at six feet. The drum membrane was somewhat depressed, the light spot was indistinct, and the Eustachian tube was partially open. There was catarrh of the posterior nares. Treatment appropriate for catarrhal otitis media was adopted, with decided benefit to the right ear, but without any noticeable effect upon the left. A more careful examination now revealed a slight and uniform bulging of the postero-inferior portion of the drum, and a smooth, pale, red body could be seen and felt by the probe through the perforation. The opening having been enlarged, a fibroid tumor of cartilaginous hardness was seen, attached by a broad base to the inner wall and filling up the postero-inferior half of the tympanic cavity. An attempt was made to remove it by the snare, but after cutting half or two-thirds of the way through the base the wire broke. The tumor was afterward seized with the toothed forceps and twisted off. The base was then repeatedly cauterized with fuming nitric acid every two to five days until the last vestige of the tumor had disappeared. An attempt was now made to secure the closure of the membrana tympani by touching the edges frequently with mitigated nitrate of silver fused on the end of a fine silver probe. This was successful beyond expectation, and the membrane was finally restored to its integrity. At the end of three and a half months the patient returned to her home much improved in general health, expression of countenance, and articulation. On the right side the watch was heard at fourteen inches, and on the left at eighteen, while the hearing for the voice was normal, and the tinnitus had entirely ceased.

Progress of Medical Science.

Recovery from Malignant Pustule.—Dr. W. E. Buck records this case (*British Medical Journal*): Mr. F——, aged thirty-one, a veterinary surgeon, experienced on October 6th a stinging sensation at the back of the right wrist. A small bleb was formed, which he scratched off, and there was some tenderness of the elbow and armpit. He had a slight rigor. On October 8th he was seen by Dr. Meadows, who prescribed some salicylate of soda and tincture of aconite, in frequent doses, as his temperature was 104°, and the rigors continued almost the whole of the day. A black eschar began to form on the afternoon of the 8th, and on the 9th it became about the size of a sixpence; its base was red and œdematous, and surrounded by some vesicles in a circular shape. The temperature was nearly 104°; the patient felt cold, and the tongue was foul. I visited the case with Dr. Meadows, and we injected pure carbolic acid under the eschar, using an ordinary hypodermic syringe. Unfortunately we could only introduce a small quantity, as it oozed out in the withdrawal of the syringe, and with it a serous-looking fluid. I dried some of this fluid on a cover-glass, stained it with methyl-violet, and found the well-known bacilli of anthrax. We prescribed large and frequent doses of soda-hyposulphite, and ordered also a large quantity of meat. Under this treatment he rapidly improved. On October 12th we again injected carbolic acid. The temperature came down, and, as the patient said he felt all right, the hyposulphite of soda was reduced to three times a day. The eschar did not finally separate for nearly six weeks, and the ulcer then soon healed. I believe that the main remedy in this case was the injection of pure carbolic acid, a mode of treatment which does not seem very painful. There was a clear history of the disease, which was contracted exactly twelve days before its first appearance, Mr. F—— having examined the flesh of an animal that had died from anthrax.

A Case of Vaso-motor Neurosis of a Rare Form Occurring in a Child.—In the *American Journal of Obstetrics* Dr. Johnston reports the following case: Mary H—— was a healthy infant until she was three months old, when she had recurrent attacks of swelling and redness of the hands and feet, which lasted during a period of three months. When five years old, and in apparent health, she had a return of attacks of the same character. The first indication of them was noticed while she was

at play in the house. The hands became suddenly red, the fingers soon turning white, then livid, and almost black. There was a sensation of pain in the parts involved, with increased sensibility to touch. The swelling lasted some minutes, and gradually passed off. While the child was out the next day the hands and ears became swollen and discolored as before. The color of the hands was bright red, but near the fingers this changed to white, while the fingers were dark purple, or almost black. The temperature of the hands was low, the fingers being very cold. From this date such attacks returned every day in the hands and feet, and in a day or two the end of the nose and the ears were also involved, being swollen, red, then white and cold. She was kept in the house for some time after this, but as she improved she began to go out. The cold air would almost invariably bring on an attack. The treatment at first consisted of warmth to the extremities by cotton-wool and bandages, lead-water compresses covered with oiled silk, and attention to diet. Hot water gave more relief to pain than anything else. Belladonna and ergot were afterward employed. In about three months there was a sudden cessation of attacks, with no return. The diagnosis of implication of the vaso-motor system is based upon the fact that only changes in the calibre of the blood-vessels could bring about the phenomena of sudden swelling, redness, and finally arrest of circulation in the part, with lividity and great coldness; and nothing could so suddenly change the calibre of the vessels except marked and sudden variations in the state of the nerves regulating their contraction and dilatation.

Malarial Urticaria.—Dr. R. De Luca, in a monograph upon the affections of the skin, due to the action of the malarial poison, relates three cases of urticaria in which there was no fever present, but which were evidently due to malaria, and which were promptly cured by the exhibition of quinine.

Large Lympho sarcomatous Tumor of the Tongue.—At a recent meeting of the Royal Medical and Chirurgical Society Dr. Jonathan Hutchinson narrated a case in which a tumor, beginning in early life in the substance of the tongue, had required removal on account of its large size. It had grown until it completely filled the mouth and obstructed deglutition and respiration. It weighed, after removal, several ounces, and was probably the largest tumor of the tongue on record. The operation had necessitated a preliminary tracheotomy and section of the lower jaw at the symphysis, since it was quite impossible to get at the mass from the mouth. The patient was a medical student, aged twenty-two, and the tumor had been growing for twelve years, or possibly much longer; it was painless, and of almost stony hardness. Its surface at one part was covered with papillary outgrowths, but there was not the least tendency to ulceration. There was no gland-disease. The patient was in good health, and the inconvenience caused by the size of the tumor was the only reason for its removal. Careful microscopic examination had been made by Mr. Eve, Dr. Klein, and others, with the result that the tumor was declared to be of a sarcomatous or lympho-sarcomatous nature. This verdict had unfortunately been supported by the final result, for, after about two years of good health, without the slightest symptom of recurrence, a new growth had suddenly developed in the scar, and, increasing very rapidly, had brought about the patient's death. The author, while admitting that the tumor, in its final development, was of a malignant or sarcomatous character, drew attention to certain clinical features which were different from those common to such growths. If not actually congenital, it had begun in very early life, and its growth had been very slow and absolutely painless. The development of coarse papillæ on its surface, without any tendency to ulcerate or fungate, was another feature of peculiarity. He had not been able to find on record any case which corresponded with his own in all its characters, but had met with several which resembled it in its early stages. In one of these, of which a portrait was shown, the appearances on the surface were exactly similar; but in this no tendency to persistent growth was shown, and the patient, a railway porter, aged twenty-three, was still free from any material inconvenience. This, and some other cases, had led the author to believe that the starting-point had been of the nature of a congenital mole, in which other morbid tendencies had been developed later on.

Circumcision a Cause of Reflex Irritation of the Genito-urinary Organs.—For some years Dr. Mastin's attention has been called to the frequency with which he is consulted by persons of the Jewish faith, on account of chronic urethral discharges, irritable urethra, and other affections of the genito-urinary organs. The main factor in these cases is a preternaturally small meatus urinarius externus, which results from the early removal, by circumcision, of the prepuce. The glans penis in a child, being covered by muco-cutaneous tissue, remains in this condition just so long as the same is protected by its natural covering, the prepuce. If, however, the prepuce is cut away at an early age, eight days or even longer, the glans becomes exposed to the rough contact of the child's napkin and other articles of clothing, and the consequence is it soon changes its muco-cutaneous condition, and becomes converted into almost true dermoid tissue; this being the condition in which we find the glans penis of every Jewish youth, as may be easily verified by examination. Since nature has wisely protected the various outlets of the body by a muco-cutaneous surface between the mucous canal and the true skin, we find these orifices remain in a normal and healthy state just so long as the muco-cutaneous tissue is preserved in its integrity. Otherwise, irritation soon runs into inflammation, followed by a deposit of retractile tissue around the orifice, which in time produces a permanent contraction. We see this to be the case in those contractions of the lachrymal puncta, after long-continued inflammation of the tarsal edge of the eyelids; in the mouth after burns or ulceration of the lips; in the anus after ulceration around its verge, and more noticeably true in a contracted meatus which follows a balanitis associated with a long-standing blennorrhagia. In children whose prepuce has been removed there is likewise a deposit of retractile tissue, that results in a contracted meatus. It has been clearly demonstrated that irritation of peripheral nerves produces centric disturbances in the spinal cord through the excito-motor system, which are thence reflected back. Histories of several cases are given in which diverse symptoms, such as incontinence of urine, sexual weakness, and painful micturition were caused by a condition of contracted meatus, and relieved by dividing and enlarging the opening.— *Gaillard's Medical Journal.*

Anisic Acid.—The already long list of new antipyretic remedies has been increased by the addition of anisic acid, a substance obtained from the oil of anise seed. It exists under the form of colorless prismatic crystals, soluble in alcohol and ether. It possesses antipyretic and antiseptic properties similar to those of salicylic acid. It also increases arterial tension. It has, however, a mild toxic effect in large doses, for when it was injected in large quantities into the veins of animals, epileptiform convulsions were caused. It has been employed with success as an antiseptic in the treatment of wounds, and seems, when employed in this way, to exert no poisonous effect.—*Gazzetta Medica Italiana Lombardia.*

Hysterical Sneezing.—Dr. Souza Leite reports a case of hysteria in which the attacks were ushered in by a fit of coughing followed by continuous sneezing. There were about forty sternutations in the minute, and the attacks lasted for several minutes.—*Centralblatt für Klinische Medicin*, August 15, 1885.

Addison's Disease in a Boy Ten Years of Age.—Professor Monti, of Vienna, has reported the following case: The boy in question was strong and healthy, with the exception of a slight attack of measles, until the age of six; the skin was quite normal in color. In July, 1880, he fell suddenly ill without any apparent cause. He had fever, with morning remissions, pain in the stomach, abdomen, and head, occasional vomiting, diarrhœa, alternating with constipation, and drowsiness, culminating in heavy sleeps which lasted two or three days, and during which no nourishment was taken; on awaking the child was very weak and was excessively emotional. At the end of fourteen days the mother noticed a peculiar yellowish-brown discoloration of the skin of the hands, and this within a few weeks spread to other parts of the body. After about five weeks the fever ceased, and the digestive and nervous disturbances gradually disappeared, but the discoloration remained. In the course of the summer the child had attacks, lasting two or three days, of headache, with vomiting, abdominal pain, and diarrhœa. In October, 1880, the boy had another illness resembling that described, and lasting from three to six weeks, during which the brownish color became darker. The child recovered and remained fairly well until the end of March, 1881, when the mother first noticed that the cervical glands were more or less swollen, and that there was a slight swelling on one of the knuckles. During 1882 the child was much the same; the muscular system was weak, but he was able to go to school. He had two more feverish attacks, one in the spring, the other in the autumn, each lasting about four weeks. The attack reappeared in April, 1883, and Professor Monti first saw the case on May 10th. The child was tall, thin, and weakly built. The hair was silky, a dark blond. The skin of the face, neck, and hands was of a dark grayish-brown color; the sclerotics were of a dirty white; the iris was light gray; the nails white. The skin of the thorax, back, and abdomen was grayish-yellow; the lower extremities were yellowish, the buttocks and perinæum darker. There were several brown spots on the external ears. The mucous membrane of the mouth was of a pale red; that of the lips and cheeks presented several brownish-black spots arranged in groups. The tonsils were enlarged. The mucous membrane of the nose and of the prepuce was pale. The epidermis was everywhere smooth. The glands of the neck were swollen; the tongue was clean; pulse, 80; respiration, 24. The thorax and its organs were normal. The abdomen was prominent; palpation painful, and especially so in the umbilical and ileo-cæcal regions. The liver was normal, the spleen somewhat enlarged. The inguinal glands were normal. The urine was light yellow, acid, of specific gravity 1.017; no albumen or other abnormal constituents; quantity natural. The blood was pale, but there was no apparent increase of white corpuscles. The temperature was normal. The patient appeared in a state of mild nervous excitement; sometimes crying, sometimes laughing. The bowels regular; he slept and ate well. On June 25, 1883, the boy had one of his usual feverish attacks, and was attended at his own home by Professor Monti's assistant. He slept almost continuously the first four days, and was quite undisturbed by the numerous flies that settled on his face. When roused, he gave his answers slowly but correctly. The pupils were equal, reacting normally to light; there was no strabismus. On sitting up the patient swooned. The glands of the neck were more enlarged. The abdomen was retracted; both hypochondria, but especially the right, were tender on pressure. The urine was normal. Within fourteen days the symptoms had subsided, and the child returned to school. On March 7, 1884, the headache, dulness, and weakness reappeared, and were followed in the night by excitement, delirium, and occasional loss of consciousness. Soon after midnight the child became somnolent, and toward morning death ensued upon an eclamptic fit. At the post-mortem examination the dura mater was found tense, thin, and hyperæmic, its inner surface shiny and smooth. The longitudinal fissure was filled with fibrinous masses. The brain-substance was soft, not congested. The posterior horns of both lateral ventricles were distended with serum. The heart was flabby, and of a dark brown color; the valves were healthy. The right lung was partly solid at the apex. The liver was enlarged and softened. The spleen was enlarged. The mesenteric glands were as large as hazel-nuts. The right suprarenal capsule was completely wanting, as well as its artery and vein. The left suprarenal capsule was very small; the greater part of its substance appeared to consist of rather vascular connective tissue. The kidneys were correspondingly large and somewhat softened.—*London Medical Record*, August 15, 1885.

Orchitis of Gouty and of Malarial Origin.—Dr. Guyot recently read at the Société Médicale des Hôpitaux of Paris, the history of a peculiar case of orchitis. The patient was an arthritic, whom he had previously treated for a rheumatic affection and a diathetic gastralgia. There were no syphilitic antecedents. The patient was placed upon an anti-arthritic treatment, under which the testicle greatly diminished in size, but at the same time the great toes of both feet and the wrist became the seat of a well-marked gouty arthritis. Dr. Guyot does not hesitate to consider the affection of the testicle as a gouty orchitis, but he has failed to mention the occurrence of rheumatic orchitis, instances of which are not rare and which bear a strong analogy to his observation. Dr. A. Zacco reported, in a number of the *Centralblatt für Klin. Med.*, 1884, the case of a man, aged thirty-five years, previously in good health, who had an attack of orchitis on the right side, with a complicating epididymitis, without having had any venereal disease or any affection of the urinary organs. After this the patient had intermittent fever for three months, complicated with tertian, and later with quotidian, and finally a continuous fever set in with orchitis. Every method of treatment was used without resulting favorably. But after it was discovered that the continuous fever reached its acme about noon, large doses of quinine were administered on the fourth day, and in two days the patient was very much better. It was observed that at the height of the fever there were slight swelling and pain of the testicles, which, however, completely disappeared with the fever. Zacco believes that the orchitis was due to the direct action of the malarial poison upon the testicles.

Benzoate of Soda in the Summer Diarrhœa of Infants.—Dr. Gnasta regards this disease as a zymotic affection, due to the presence of a special microbe. The predisposing causes are a defective hygiene and excessive heat, and the exciting cause, indigestible food. He has used benzoate of soda with success, giving about one drachm dissolved in three ounces of water in the twenty-four hours. A dose of calomel or jalap is given at the commencement of the treatment, and on the third day a slight purgative action is again obtained by the administration of magnesia. Fasting is enjoined during the treatment, no milk nor beef-tea being allowed, but only a few spoonfuls from time to time of lemonade, or good wine. Nursing children must, however, be given the breast, but not more than four times in the twenty-four hours.—*Journal de Médecine de Paris*, August 23, 1885.

The Micrococcus of Infectious Vulvo-vaginitis in Children.—In a paper read before the Society of Physicians, in Buda-Pesth, Dr. Cseri reported the results of his investigations in this disease. He had examined the vaginal secretion in upwards of thirty cases occurring in girls between three and ten years of age, and found constantly a micro-organism which seemed, both in its microscopical appearance and in its action in cultures, to be identical with the gonococcus of Neisser. The following were the author's conclusions (*Centralblatt für Klinische Medicin*, August 8, 1885): 1. A large porportion

of cases of so-called catarrhal vulvo-vaginitis, especially the chronic forms, are distinctly infectious. Whether those cases occurring after the exanthemata are also infectious cannot yet be definitely asserted. 2. In the secretion in the infectious form there is always present a characteristic coccus, which in its form, size, and action in culture fluids, is not to be distinguished from the gonococcus. As regards the question of its pathogenic nature and its identity with this specific coccus, further investigations with pure cultures are necessary. 3. Vulvo-vaginitis is exceedingly contagious, and there is great danger to the eyes if any of the secretion is brought in contact with the conjunctiva. 4. Infection is carried through clothing and bed-linen, public bath-tubs, etc. Prophylaxis consists in isolation of children affected with vulvo-vaginitis and in disinfection of the underwear.

Intratracheal Injections.—Some experiments made by Dr. Pernice show that liquids injected into the trachea drop by drop, or in little jets, run down the posterior surface and are thence evenly distributed throughout all the bronchial twigs. They are then absorbed by the pulmonary veins or by the lymphatic vessels, and thus exert both a local and a systemic action. When the animal was placed in the supine position, with the head elevated a little, no cough was excited by the operation. Dr. Pernice used in his experiments distilled water, milk, and defibrinated blood. Absorption was complete, and no respiratory trouble of any sort resulted. He also employed solutions of tannin, borax, benzoate of soda, quinine, morphine, and nux vomica and lime-water, without exciting any reaction in the respiratory mucous membrane.—*Il Movimento*, No. 12, 1885.

Malarial Colic.—Dr. F. Sancho relates the case of a woman, aged twenty-seven, of good health, married, and the mother of two children, who became pregnant for the third time. She complained first of loss of appetite and of a bad taste in the mouth, and later suffered from colicky pains and vomiting. These came on every evening between four and six o'clock, lasted for a few hours and then subsided, and were succeeded by profound and tranquil sleep. The tongue gave no evidences of catarrh of the digestive tract, and indeed there were no dyspeptic symptoms of any kind except during the times mentioned. The symptoms were referred to the woman's condition, and it was thought that they would disappear after the birth of the child. However, after a time the patient was taken with a heavy chill, accompanied with intense abdominal pains, and soon abortion occurred. That same evening the gastric pains and vomiting returned just as before. Anti-dyspeptic treatment was tried, but without any improvement resulting. Then, thinking that malaria might be the cause of the trouble, Dr. Sancho prescribed quinine, and the patient was speedily cured.—*Revista de Medicina y Cirurgia Prácticas*, July 7, 1885.

Sunlight as a Disinfectant.—At a recent meeting of the Academy of Science of Paris, M. Duclaux detailed the results of some experiments which he had made to determine the effect of sunlight upon the vitality of microbes. He found that a few hours of exposure to the direct rays of the sun were sufficient to weaken, and finally to destroy, the pathogenic micrococci used in the experiments. He argued, therefore, that the sun was the best disinfectant which we possess, the most universal, the most economical, and the most active.—*Le Progrès Médical*, August 15, 1885.

Retention of Urine in a Child Six Months Old.—M. Arnozan relates in the *Journal de Médecine de Bordeaux* the case of an infant, six months old, in apparent good health, who was suddenly seized with retention of urine. Previous to this time he had always passed water without difficulty and in sufficient quantity. No urine passed for thirty-six hours, although the child made ineffectual straining efforts. The bladder could be felt as a tense ball in the hypogastrium. The testicles were drawn up into the abdomen and could not be felt in the scrotum, but nothing abnormal could be discovered to account for the retention of urine. The water was drawn without difficulty through a filiform elastic catheter. There were about four ounces of clear though dark-colored urine. The child was put upon small doses of potassium bromide, and after the water had been drawn for about twelve days, it began to flow normally, and has since continued to do so, though the child has always a temporary difficulty in urinating whenever he is a little indisposed.

Nasal Polypus in an Infant.—M. Krakaver exhibited before the Belgian Academy of Medicine a child who when only four and a half months old was brought to him on account of a trouble of the nose. He removed twelve polypi from the right nasal fossa, cauterizing the mucous membrane with nitrate of silver. Mackenzie states that the youngest child whom he had seen affected with nasal polypi was sixteen years old, and Semon mentions having observed one twelve years of age. The case reported by M. Krakaver would therefore seem to be exceptional as regards the age at which the disease appeared.—*Revue Médicale*, August 22, 1885.

The Relations between Diseases of the Abdomen and those of the Right Heart.—Since the work of Potain in 1878, and the researches of Tessier and Franck in 1879 and 1880, this question has received little attention. Passerini now cites three cases of tricuspid insufficiency consecutive to a peritoneal effusion. Auscultation showed a prolongation of the first sound and a murmur; the second sound being found strengthened toward the pulmonary orifice. The disappearance of the effusion was accompanied by the disappearance of these sounds. Passerini believes the cause of these cardiac alterations to be purely mechanical; the compression of the abdominal viscera provokes venous anæmia, and engorgement and hyperæmia of the thoracic organs. In favor of this explanation we have the observations of Larcher and of Depaul in pregnancy. These writers have noted the accentuation of the first sound toward the pulmonary orifice, at the same time that it is prolonged at the level of the base of the xyphoid cartilage. The same observation has been made in two cases of ovarian cyst, and in another of large abdominal tumors; and finally, this same modification of the first sound at the pulmonary orifice can be produced by simple compression of the abdominal wall.—*Revue Bibliog. des Scien. Méd.*, July 31, 1885.

Hydræmia and Hydræmic Œdema.—The relation of œdema to diminished concentration of the blood is a subject that is still open to debate. Professor Salvioli has recently made an experimental study of the question (*Archive delle Scienze Mediche*) which goes to show anew that dropsy depends upon a variety of conditions. It is connected firstly with the hypo-albuminotic state of the blood, conjoined with hydræmic plethora; then with the physiological or morbid constitution of the vessel-walls; lastly, with the degree of pressure and tension of the blood in the vessels. This last factor has great importance in the production of hydræmic œdema, and regulates its degree and disposition according as in simple plethora, or in hydræmic plethora, the energy of the cardiac contractions is augmented or enfeebled. Only in hydræmia consecutive to acute nephritis there is observed constant elevation of the blood-pressure, which is maintained by the hypertrophy of the left ventricle. In this first stage œdema occurs, which may be called active, localized especially in the skin, that is, in the point where in man there exists the greatest permeability of the walls of the vessels. In the later stage, common so-called passive œdema occurs instead, which resembles in its disposition the œdema of heart disease, and is dependent on altered nutrition of the myocardium, and consequent lowering of the arterial pressure and increased tension in the venous system.

Jaundice and Pain in Biliary Colic.—Dr. Lawson Tait, in the *Lancet*, discusses the reason why, during the passage of gall-stones, there is frequently no jaundice. In fifteen cases of cholecystotomy he found no history of jaundice, and Dr. Tait has found that the occurrence of jaundice, either in the skin or in the urine, during and after the passage of gall-stones, is of extreme rarity, and not, as has been believed, common. Dr. Tait seeks for an explanation of this fact in the following anatomical conditions of the cystic and common ducts. The common duct is not so long (three inches) as most text-books assert, and is much less rigid and more easily dilatable than the cystic duct, which is larger than most of the text-books describe it, viz., one inch. Hence we can understand how a stone, if not of very great size, will cause intolerable agony while passing through the unyielding cystic duct, and without a trace of jaundice ensuing, the gall-bladder alone being its propellent force; but the moment it enters the common duct the extending impulse will be increased by the influence of the whole excreting force of the liver, so that its passage through the common duct is more rapid. The chief symptom, then, that of pain, is due to the slow passage of the calculus through the unyielding cystic duct, while its rapid passage through the easily distended and much larger common duct gives no time, in the majority of instances, for the production of jaundice, which only takes place after long-continued obstruction of this, the common duct.

Epidemic Purpura.—Dr. Guelliot (*Annales de Dermatologie et de Syphiligraphie*), observed, in infants between the ages of seven months and three years, three cases of purpura. The eruption was preceded by convulsions, vomiting, and intense dyspnœa, then coma, and, in one case, acute pain in the lumbar region. After a few hours purpuric spots appeared symmetrically on the anterior and inner surfaces of the thighs, at first dull in color, then turning successively a bright red, purple, and finally black. In the three cases the course was rapid, death occurring after fourteen, fifteen, and twenty hours from the onset. The illnesses were attributed to unhealthy conditions of the street in which the children lived.

Deep Massage of the Abdomen in Intestinal Obstruction.—Dr. Kriviakin (*London Medical Record*, August 15, 1885) warmly recommends deep massage of the belly as a powerful curative in cases of intestinal obstruction. The procedure, as practised by him, "requires only one assistant, the name of which is Patience," and consists in the following: The operator anoints his hands with oil, separates the thumbs as much as possible from the first fingers, puts the thumbs in juxtaposition, places the hands at the lower part of the belly (the patient lying on his back), and, while producing steady and strong pressure, passes his hand first from downward upward, then *vice versâ*, then from the right to the left, and so on, repeating the manipulations for twenty minutes, by the end of which time "a regular peristaltic storm is set up within the abdomen." Then the patient (who at the beginning of a sitting feels rather uncomfortable, but in about ten minutes commences to experience distinct relief) is left alone for the next hour and a half, when another sitting of deep massage for about fifteen minutes may be tried. As a rule, however, one sitting is sufficient for producing stools. It happens very often that in the course of the manipulations a distinct, usually elongated, sausage-like tumor may be felt in the belly. If this be the case, fairly strong tapping at the spot of the tumour should be added to the shampooing, each stroke being finished by a strong localized pressure. According to the author, deep massage is indicated in intestinal obstruction of every kind and description. He adduces the details of four cases of the affection met by him lately among Dagestanese, and treated after this energetic plan (very energetic, indeed, especially in comparison with foul eggs or a cock's excrements, with which obstructed patients are usually treated by numberless native medical men, so-called *khakims*). One of the cases was that of a strongly built man, aged twenty-four, with constipation of ten days' duration, agonizing paroxysmal abdominal pain, fetid vomiting, obstinate hiccough, offensive eructation, and moderate distention of the belly. A volvulus (caused by severe physical exertions soon after a liberal meal) was diagnosed, and deep massage was resorted to after a large enema made of a weak infusion of tobacco-leaves. In about ten minutes, after a sitting of twenty minutes' duration, very profuse and extremely offensive defecation followed; later on, the patient's bowels were moved five times more. In another case, where constipation of eight days' duration and fecal vomiting were present, deep massage was performed twice, with an interval of one hour, defecation ensuing during the second sitting. In the third case, with eight days' obstruction and obstinate hiccough, recovery followed after the simultaneous use of deep massage, large enemata, and cold compresses. Less fortunate was the issue in a fourth case, that of a weak, decrepit man, aged fifty-five, with constipation of twelve days' standing, filiform pulse, fetid vomiting and eructations, cold viscid perspiration, and a semi-comatose state. Though regarding the case as a hopeless one, the author still decided to try massage, after the previous administration of two grains of camphor and a high effervescent enema. In about half an hour after the manipulations, a free discharge of hard fecal lumps, suspended in fluid, ensued. But collapse became worse, and five hours later the old man died. No necropsy was allowed.

The Distribution of the Blood in the System.—Dr. Spehl has instituted a series of investigations having for their object an inquiry into the amount of blood contained in some of the principal organs during life, also to establish experimentally the invariableness of these quantities or their fluctuation in correspondence to varying states of these organs; in the latter case to ascertain when and how they vary within physiological limits; and finally to draw certain practical deductions from his observations. The results obtained by the author may be briefly given as follows: (*London Medical Record*, August 15, 1885) *Lungs.*—1. During inspiration these contain about one-thirteenth of the total amount of blood. 2. During expiration about one-eighteenth. (These experiments were made on rabbits.) 3. These values are not influenced by varying pressure in the heart during normal respiration. 4. An insufflation of compressed air in the trachea, the external pressure remaining the same, drives the blood contained in the lungs out, so as to reduce its ratio to one-sixtieth. In connection with his study of these organs, the author has also investigated the effect upon the pulmonary circulation of residence in and ascent to high altitudes, and has come to the following conclusions: (*a*) During a sojourn in a rarefied atmosphere the division of the blood is physiological, and consequently the same as at the sea-level. (*b*) During ascent there is a tendency to congestion of the lungs, and, *cæteris paribus*, this congestion is the more marked and persistent the more rapid the ascent may be. *Brain.*—During the waking state this organ contains on an average one-eighth of the total mass of blood, during sleep the one-twelfth. *Muscles.*—These contain more blood during contraction than during repose. One-sixth to one-tenth of the total mass are the extreme figures found.

The Pharmacopœias of Different Countries.—According to Robert, the French pharmacopœia contains the names of two thousand different preparations, while that of Norway has but five hundred and thirty. The United States come seventh on the list of sixteen. Russia and the Latin races would appear to have the greatest fondness for, or faith in, drugs; while the German and Scandinavian peoples, to judge from the comparatively small number of articles in their pharmacopœias, are much less given to dosing.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, October 10, 1885.

THE CHOLERA CONFERENCE IN BERLIN.

THE report of the second conference upon cholera, held in Berlin in May of the present year, has been published. The discussion was almost interminable (the report of it fills seventy-seven closely printed pages, somewhat larger than a page of THE MEDICAL RECORD, and is issued as a supplement to the *Berliner Klinische Wochenschrift* for September 14 and 21, 1885), but it lacked the interest of the one of last year, as there was little of novelty developed during its progress. The first subject for discussion was the new discoveries made since the last session regarding the cholera bacteria, especially as to the forms under which they preserve their vitality. Koch spoke at great length, and defended his position against the attacks which had been made on him by Klein, Finkler and Prior, and others. He endeavored to show that their methods of investigation were faulty, or that they had not been able to distinguish between his bacillus and other forms of microbes. As to the claim of priority made for Pacini, he thought it very doubtful whether this observer had really seen the true cholera bacillus, and said that he himself had never heard of the alleged discovery until long after he had published the report of his own investigations. In discussing the question of disinfection, he expressed his decided preference for carbolic acid over any of the metallic salts. The speaker said that a permanent form of the cholera bacillus had not yet been discovered, and perhaps there was none. But such a form was unnecessary, since the bacillus would live in moist earth for five months or longer when the conditions were otherwise favorable. A discussion then ensued between Koch and von Pettenkofer, the latter maintaining that the characteristics of the different cholera epidemics furnished conclusive evidence that the cause of the disease could not reside in a specific bacillus. He thought that cholera was no more contagious than was malaria. The question of experiments upon animals was also discussed, but without developing any points of especial interest.

The second and third points proposed for discussion were that of the spread of the disease through pilgrimages and by ships, and the influence of the soil, air, and water upon this spread. Koch said that the facts in support of the view that the disease was spread by human intercourse were incontrovertible, and he thought that there lay a danger to Europe in the railways now being built in Central Asia, on the completion of which India and England would be separated by a journey of only eleven days. He expressed himself further as of the belief that one attack of cholera confers immunity against subsequent attacks, at least temporarily. He explained in this way the fact that cholera is spread in waves along the paths of human travel from its endemic seat toward Northwest India. Each epidemic in these parts, he said, left behind it an immunity which existed for three or four years. At the end of that time the communities were no longer protected, and another invasion of the disease occurred. Bryden had called attention to this periodic overflow of the cholera, but had wrongly attributed it to the influence of the monsoon. Koch thought that the history of an epidemic on the ship Matteo Bruzzo was a sufficient answer to von Pettenkofer's theory. In this case the disease appeared on the thirty-fourth day, and the last case declared itself on the fifty-second day after the vessel had left port. If now the contagium could exist only in the ground, the ship not having touched land since starting, it was necessary to believe that the incubation period of the disease was from thirty-four to fifty-two days in length. The speaker thought that immediate contagion was rare, but the intervention of clothing or some other suitable soil for the development of the bacillus was necessary. Virchow said that, as far as he was aware, no facts were in existence in proof of the theory that cholera germs could be carried directly to man from the soil, as could the malarial poison. He thought, however, that the opposing sides in this controversy could reach some agreement if one would admit that cholera bacilli could grow in the earth and the other that they could grow in agar-agar and in soiled clothing.

Then Koch spoke at great length against the assertion that the rise or fall in the level of the sub-soil water bore any relation to the severity of an existing cholera epidemic. Von Pettenkofer defended his views on this point at equal length, but no new arguments were brought forward on either side.

The last question brought forward for discussion was that of the measures proper to be taken against the cholera, but here, as elsewhere in the conference, nothing new was developed. Koch enumerated various measures of disinfection, cleanliness, thorough cooking of food, etc., and repeated that he considered carbolic acid as the most practicable disinfectant which we have at our disposal. Virchow remarked that if a strict quarantine were possible, as, for example, on an island, he would be in favor of it, but he regarded a land quarantine as wholly impracticable. Von Pettenkofer said that when the cholera visited Bavaria in 1836, it was universally regarded as non-contagious, and people acted upon this belief. Of course there was no disinfection, but further than that no especial efforts were made in the direction of cleanliness, and no attempt was made to isolate the sick. Yet, notwithstanding all this, Bavaria, and especially its chief city, Munich, had never been visited by so mild an epidemic as this. He thought that even if measures of thorough disinfection and isolation could not be carried out, there was no occasion for alarm or special anxiety. The question of the diet of individuals in time of an epidemic was broached, but Koch said that as yet no special rules could be laid down.

In the course of his remarks Koch took occasion

several times to attack Cunningham's views, and said that these were not held by many of the other medical men in India, but that they were afraid to express their real convictions if opposed to those of Cunningham, as they would be in danger of losing their positions. Von Pettenkofer defended Cunningham's character, but Koch repeated his assertions several times. If these charges be true, their public statement may lead to a reform in the Indian Medical Service, and then the second cholera conference will have accomplished something after all.

After an exchange of compliments and of apologies for any acrimonious remarks dropped in the heat of debate, the members bade adieu one to the other, and the conference was at an end.

Besides those mentioned, Kersandt, Fränkel, Pistor, Günther, and others participated in the debates.

A WORD OF ADVICE.

At this season of the year our city receives a material addition to its population, classified under genus, student —species, medical. We trust that all the gentlemen included in this category have come to the metropolis with a zeal for study, with habits of perseverance, and with a desire to do creditable work. This new body will contain many recent college graduates as well as those whose previous scholastic privileges have been more scanty. May we offer to both classes alike a word of advice, which we hope they will heed? To both alike it may not come amiss, for the evil against which we would warn them is rife in undergraduate as well as professional schools. Many acquire it early in their course of study, and despite their efforts to emancipate themselves, they remain in perpetual bondage. We would name this evil —lack of independence in study.

By a man of independent scholarship we understand one who relies on text-books and lecture notes for only an outline of what to study, who regards them as only a means to an end. He may not be a genius. He may be below the average. He does not accept facts, however, unless he understands their relation to other facts; in short, he assimilates what he studies. Hence his armamentarium, small though it may be, is yet brightly polished and ready for instant use. He may graduate at the foot of his class, but he has learned to think readily and accurately. Such thought leads to decisive action. He has within himself the elements of assured success.

Contrast with him the man who relies wholly on text-books and lecture notes, who does not develop a single independent sturdy idea.

He may stand high at the final examinations, but he lacks real mental vitality. He has not developed that "emergency" element so prominent in action in the life of a physician. He has laid narrow foundations and has not a warranted self-confidence. Many men are now about to begin their course of medical study. Hundreds have come to New York for the first time. To all of them we would give this exhortation, "think for yourselves." Be no man's servile imitator. To do independent work requires courage. There are many difficulties to be overcome. Many apparent contradictions will require reconciliation. If these ends cannot be attained after reasonable exertion, let a clue be given by the instructor. It is his business to aid the student by the development of the latter's mental resources. Then when the student lays aside any work as finished, he is able to give a reason for the hope that is within him. "That's right, why?" is a frequent class-room expression of a professor of mathematics, in one of our leading universities. The phrase illustrates the spirit in which all true study should be conducted.

Most men make the mistake of attempting too much the first year. Anatomy, physiology, chemistry, and physics alone are a sufficient task for the majority, especially if laboratory work in these branches be followed in addition to the lectures. Of course the amount of work which can profitably be undertaken depends on a man's previous experience, but we would earnestly advise that all the spare time of the first year be devoted to anatomy. This subject is at examination time the student's bugbear, primarily because he did not at the outset recognize its relative importance and did not govern himself accordingly. It is a difficult subject to learn and an easy one to forget, because from its very nature the greater part of it is purely arbitrary and has to be learned by rote.

One word more in regard to clinical instruction. There is a fascination about attending clinics, but it is simply a waste of time until a man has by study fitted himself to appreciate them. Otherwise, having eyes, he sees not; having ears, he hears not. Clinical instruction will come in due time, but it is strong meat not adapted to the milk age.

A most praiseworthy aim it is to shape one's course as to compete for a hospital position upon the attainment of a degree. The competitive examinations for these positions are free from many restrictions which cluster about college examinations. The best man wins, and he is rightly adjudged best who can answer practical as well as theoretical questions; who is, to use a common phrase, the best "all-round" man. This status of scholarship is not attained by servile study, but by fearless, independent thought. One need not despair of success. There are, we believe, more good hospital positions offered here every year than there are thoroughly first-class men to fill them. Thus, with such a combination of theory and practice will a man go forth into the world conscious of his own mental integrity, confident in his own powers, and bound to do well. He has laid a firm corner-stone, the superstructure will be solid and permanent.

THE REUNION OF THE PROFESSION ON THE MATTER OF CODES.

In an address delivered before the New York Academy of Medicine, and published in the Medical Record of October 3d, the learned President takes occasion to offer congratulations upon the prospective reuniting of the profession on ethical issues. He refers to the explanatory declaration of the American Medical Association made at its last meeting.

This declaration sets forth that, no emergencies or circumstances can make it necessary or proper to *enter into formal consultation*, with those "who assume a name indicating to the public a sectarian or exclusive practice, or belong to an association or party antagonistic to the

general medical profession." The declaration also states that the National Code "does not exclude from professional fellowship on the ground of differences in doctrine or belief;" nor is there any article "of said Code of Ethics *that interferes with the most perfect liberty of individual opinion and practice.*"

Dr. Jacobi shows with natural satisfaction the close resemblance between the principles set forth in this declaration and those of the Code of Ethics of the Medical Society of the State of New York. He says:

"After these resolutions had been passed in New Orleans, many of the professional men who always persisted in adhering to the Code of the American Medical Association, were of the honest opinion that they had, by accepting them, removed every discrepancy of opinion or difference of action on the part of those adhering to either the Old or New Code. For it is true that the explanatory declaration of Chap. II., Art. IV., Sec. I., exhibits a great resemblance to the New York Code of 1882. For the Medical Society of the State of New York it must be a source of intense gratification to be convinced, by the passing of that declaration, that a few years have sufficed to so change public opinion as to oblige even the American Medical Association to recognize the justness of most of the New York proceedings. Upon this result the New York State Society can but be sincerely congratulated, and the spirit of equity and justice, as displayed by the Committee drafting the explanatory declaration, must be commended."

We trust that Dr. Jacobi interprets rightly the spirit exhibited by the framers of the declaratory resolution. It certainly seems that under its provisions regular physicians can meet in formal consultation many who hold to the doctrine of homœopathy, and can meet in cases of emergency, though not "in formal consultation," any legal physician who seeks their services. In other words, the hard and fast rule—which has been tacitly if not formally upheld—forbidding consultations with all homœopaths, is set aside. There is, in fact, given "the most perfect liberty of individual opinion and practice" to the members of the American Medical Association.

There can be no doubt that the medical profession is gradually reaching complete harmony on the subject of its relations to irregular practitioners. No one will again be punished simply for consulting with a homœopath, or eclectic; but the whole drift of professional feeling will be more strongly than ever set against associating with men who are believed to be dishonest, ill-educated, or quacks.

THE HEALTH AND FERTILITY OF EDUCATED WOMEN.

An instructive report upon the health of college alumnæ has recently been published. It is based upon statistics collected by a Special Committee of the Association of College Alumnæ, of whom Miss Annie G. Howes is Chairman. Circulars of inquiry were issued to one thousand two hundred and ninety alumnæ, and answers from seven hundred and five of these were obtained. The colleges in which the higher education was bestowed were twelve in number, and included Vassar, Smith, Wellesley, Cornell, Oberlin, and Wisconsin. The history of the seven hundred and five is briefly given as follows: The average age at which they began to study was 5.64 years, at entering college 18.35 years, and the average present age is 28.58 years. During college life the majority studied but moderately, and only forty-four per cent. did not worry over their studies or affairs. Since graduation all seem to have found congenial occupation, a great many as teachers, while eight only are occupied with social duties to the exclusion of other occupations. Somewhat over one-fourth have married, and of the whole number of children borne by them the greater part are living and in good health. On entering college 78.16 per cent. were in good, 1.98 per cent. in fair, and 19.86 in poor health. Since graduation the percentages are 77.89, 5.11, and 17.02, respectively. In other words, 138 report a deterioration in health, 418 have had no change, and 149 show an improvement in health. The most prevalent cause of disorders is constitutional weakness. The present health of graduates seems to have been affected according as their parents have enjoyed either good or poor health, the figures showing three per cent. increase in health for those whose parents were both in good health, and a decline in health of over seventeen per cent. for those whose parents were both in poor health. For those who entered college at sixteen years of age or under, an increased deterioration in health of between ten and eleven per cent., as compared with those who entered at a later age, is observed.

The conclusion from the above is that which any observant physician would independently have drawn, viz., that the health of women is not much affected either one way or the other by an American college education. We know no especial reason why any deterioration should be expected, and we confess that, so far as this point is concerned, the statistics will have their chief value in the relief of lay prejudices.

It may as well be borne in mind, however, that out of some ten millions of women in this country, there are less than two thousand who have received a classical education, and it is very safe to say that those who have won this distinction are not exactly types of the average woman. Even if they were, however, it is rather straining a point to speak of our college alumnæ as "highly educated," simply because they have gone through an American college for women. It is the later and harder struggle for technical and professional learning that breaks down the aspirant for a real education. This later struggle our college alumna rarely enters, but she becomes a school-teacher, and that ends her.

Some interesting facts are brought out with regard to marriage and fertility. Of the 705, only 196 or 27.8 per cent. are married. Of those married, 66, or over one-third, have had no children. The remaining 130 have had 263 children, of whom 232 are living. This gives an average of two children per family, the parties having been married on the average six to seven years. It will be seen that the college education of women does not as yet promote connubiality or fecundity.

Some interesting facts are given regarding the establishment of the menstrual function. The average age at which this was established in 705 women, was 13.62 years. There were 169, or 23.97 per cent. only, who

reported having experienced no trouble during the menstrual period.

Nervousness appears to be quite common (in 333 out of 705), although in the great majority of cases it had nothing to do with education. Indeed, education properly conducted tends to lessen nervousness.

One more fact of interest, if not of significance, and we conclude our review. It appears from the tables that the 361 who began study at or under five years of age, give about the same report as to health as do the 328 who did not begin study until later.

DECLINE THE INVITATION.

The month of grace allowed for the return of the gentlemen who withdrew from the organization of the Ninth International Congress has passed. There are no signs, yet of the hoped-for return.

The possibility, as suggested by us last week, of affecting in some way the ruinous course of the present Committee, is now destroyed by the recent action of the Executive Committee, which has formally assumed dictatorial powers.

We think, therefore, that it would be better, for the credit and harmony of the profession, that the acceptance of the invitation to hold the Ninth International Medical Congress in this country be withdrawn.

CHEAP DYING.

The cost of cremation by the new company in this city, it is said, will be only twenty-five dollars. The fact that a person dying in New York can have suitable mortuary rites performed for the comparatively small sum of twenty-five dollars is most interesting, and will, we feel sure, do much to rob death of its terrors. The company, indeed, promises to open up a new era in municipal mortuary history; for while there has been a great deal said and written here about cheap living, we have heard but very little of a serious and practical nature about cheap dying. Dying in New York is a luxury, and one about which most people show a strange amount of thoughtlessness and inconsideration. A citizen can live three years in Arkansas for the price of a conventionally respectable interment in New York. Yet few take such a fact as this into the slightest consideration in consenting to a demise. We are, indeed, acquainted with one conscientious old Irish woman, with a complication of diseases, who faithfully attends her Dispensary, because she is "on her relations," and she knows and admits that they cannot afford to bury her.

Such a spirit deserves a historical record and wide emulation. The fact is, we are much in need of a Society for the Cultivation, not of plain living, but of Plain Dying. In these hard times it is often little less than criminal that a man subject his estate to the prolific expenditure of a funeral. We have heard of a gentleman who, at the solicitation of his wife, gave up tobacco and thereby, in the next fifteen years, saved over five hundred dollars, which all went at last for his burial expenses. Here was certainly a disproportion between effort and its result that is most painful to well-balanced minds, and very disheartening to the anti-tobacco propaganda.

We do not advocate extremes, however. It appears quite possible that if a person can die respectably for $25, not only is final dissolution within the reach of all, but it may even be a positive temptation, and lead to the cutting off of a large amount of agreeable, not to say lucrative, invalidism. The whole matter of cheap dying, in fact, needs much further discussion. At present the subject is in a state of painful confusion, reminding one, in this respect, of the Germ Theory, and of the Ninth International Congress.

News of the Week.

The First Meeting of the Executive Committee of the possibly International Medical Congress, was held in this city, on September 24th, ten of the twenty-one members being present. Dr. Henry H. Smith, was elected Chairman; Dr. F. S. Dennis, Secretary. The latter gentleman was also elected Associate Secretary-General.

The Committee does not seem to have done anything except to pass a declaratory resolution emancipating itself from the authority of the American Medical Association, as follows:

"*Resolved*, That this Executive Committee enters upon the management of the affairs of the Ninth International Medical Congress, with the understanding that, in accordance with Rule No. 10, its powers are not restricted, except by the rules and regulations adopted September 3, 1885, by the Committee of Arrangements appointed by the American Medical Association in April, 1885; and that the actions of this Executive Committee are final, not being subject to revision, amendment, or alteration by either the Committee of Arrangements or the American Medical Association.

It is rather unfortunate that the original committee did not think to adopt some such resolution as the foregoing.

A New Journal.—The *Cincinnati Medical and Dental Journal*, is the title of a new monthly journal, published in Cincinnati. It is edited by Dr. Sage and Dr. Thrasher; and so we expect that it will show wisdom and concussive vigor.

The Origin of the Montreal Epidemic is believed by many to be as follows: In the month of March, 1885, the city having been free from the disease for three years, a conductor in the employ of the Pullman Palace Car Company arrived from Chicago and was taken to the Hospital Hotel Dieu with an eruptive disease. He was placed in a ward with other patients, and, as it afterward was ascertained, passed through the stages of a mild case of variola. A nurse, who took care of this conductor, contracted small-pox and died. In this manner the present epidemic had its origin, according to the statements of the Board of Health. It is quite possible, however, that the disease existed in Montreal previously and was unknown to the Board of Health. In the month of April, 1885, the pest-house of St. Roch was opened and there were 6 deaths. In May, 10 died of the disease; in June, 13; in July, 46, and in August there were 241 deaths. In the early summer the venerable Bishop of Montreal, M. Borget, was gathered to

his fathers, and his public funeral was attended by thousands of the faithful. Coming as many of them did from tenements reeking with pestilence, the contagion was disseminated among the immense concourse of those who were in the church, and a marked increase in the death-rate was at once apparent. Since September was ushered in the death-rate has climbed to its present proportions, and the returns for the month will show a mortality of upward of 1,200 from the grisly destroyer. The seat of the pestilence is in what is known as the East End. Montreal, like most other cities, has its court end and its poorer section. The English-speaking population inhabit the western portion of the town, with the mountain for a background, while the French inhabitants almost exclusively reside in the immense district lying east of the big stone municipal palace on the Champs des Armes.

The Preventive Inoculation of Yellow Fever seems to be suffering from the same marasmus as does the preventive inoculation of cholera. In a session of the Imperial Academy of Medicine on September 14th, at Rio de Janeiro, Dr. Araujo Goes claimed to have shown Dr. Freire microscopic preparations of earth taken from his yard, on the Praia de Flamengo, in which was the bacillus discovered by Dr. Freire. Dr. Goes further states that Dr. Freire having failed to discover the sporuliferous cells (*cellulas sporadulas*) in the preparation, he sought for these and in a short time showed them to his colleague. He kept the matter quiet with the intention of not discrediting Dr. Freire, but he now regretted his action. On the 17th, the emperor is said to have examined microscopic preparations made by Dr. Vieira de Mello, who claims to have discovered a bacillus in the excretions of patients suffering from acute and chronic malaria, exactly similar to that discovered by Dr. Freire in the excretions of yellow fever patients.

The Cost of the Plymouth Epidemic, according to the Philadelphia *Ledger*, is about as follows: The price in human lives was 107. There is no way to equate that in terms of money. The cost in dollars was nearly sixty thousand in extra expenditure, and about the same sum in loss of wages from enforced idleness among the sick and those who had to wait upon and nurse the sick —in all about one hundred and twenty thousand dollars. Costly experience that for a little town like Plymouth, but the remaining consideration is, Will the people there profit by it?

The Montreal Epidemic.—It is difficult to get the exact truth with regard to the amount of small-pox now in Montreal. For the week ending September 23d, there were 235 cases officially reported. Since then the number of deaths daily from the disease has ranged between twenty and sixty. Estimates as to the present number of cases reach nearly to 4,000. There is some evidence that the epidemic is declining. The Board of Health has not had very much authority—and, perhaps, less inclination—to deal vigorously with the epidemic. It has perhaps been too severely criticised, however, for not doing what it really had no power to do. The prejudice against vaccination among the French Canadians is still very strong, but is yielding a little to necessity, and spiritual and municipal authority. It would be less difficult to overcome traditional prejudice on this subject in the city but for the frightful examples set by those to whom the ignorant look up as guides. A correspondent of *The Times* writes: "Dr. Legault, a physician practising in St. Jean Baptiste, had small-pox in his own family without isolating it or reporting it to the authorities, nor did he let that circumstance deter him from going daily rounds among his patients, thus making himself no doubt an agent for spreading contagion." It is stated also that another physician, one of the staff of the French Medical College, a very influential man among his people, is a fanatic on this subject. He not only publicly denounces the method of Jenner, but he teaches non-vaccination to the students at the Victoria College. It is reported that there are several other "cranks" of his kind in the list of the French medical profession, and the result of their open prejudice against scientific repression of the small-pox is that the ignorant masses have become thoroughly imbued with the fatal error. There is another story to the effect that, a number of years ago, owing to the use of impure virus, many people, especially children, became impregnated with scrofula and other noxious disorders. Politics also entered into the question. There are many small demagogues among the French who are always striving to stimulate race prejudices.

Dr. Charles F. Withington was the author of the paper to which reference was made in the editorial of September 26th.

New York College of Veterinary Surgeons.—The opening lecture before the New York College of Veterinary Surgeons was delivered on Saturday evening, October 3d, by Professor James Law, F.R.C.V.S., of Cornell University. The regular session of the college commenced on Monday, October 5th.

The International Medical Congress.—"It will also be noticed that the opinions of certain distinguished foreigners with reference to the committee's office and work were ignored *in toto*, not being accorded even the courtesy of a polite remonstrance. The committee has doubtless done just the work its manipulators set to its hands; but, whether its policy be voted wise or foolish, the denouement will show that the breach between the opposing parties is widened beyond repair, and that the contending voices are dissonant beyond the hope of harmony."—*Louisville Medical News.*

A Doctor and His Spiders.—The daily papers announce the death of Dr. Francis A. Daeumer, one of the oldest physicians in Paterson. He had been for many years one of the remarkable characters in Paterson. His father was a prominent government officer in Bohemia, where the doctor was born nearly seventy-seven years ago. He was liberally educated in Saxony, studying medicine at the Universities of Bonn and Magdeburg. The doctor was licensed in 1840, and served for six years in the Prussian army, as Surgeon of the Eighth Brigade and Seventh Regiment of Lancers. In 1848 he took part in the revolution, was arrested for high treason, and sent to prison, where he spent four years in the dungeons of Rastadt, Ehrenbreitstein, and Julich. While in these prisons, often doomed to solitary confinement, his only companions were the spiders that festooned the walls of his dungeon. He conceived a strange attachment for

these repulsive creatures which he never forgot. The doctor came to America in 1857, and has lived in Paterson ever since, enjoying a moderate practice, and the general esteem of the German-Americans, with whom he almost exclusively associated. He owned a house in Ellison Street, renting out part of it, and occupying two or three rooms himself, and living entirely alone. From his love for spiders he would allow no repairs to be made to the rooms, while house-cleaning was out of the question. The dust of many years was allowed to accumulate undisturbed, and his beloved spiders multiplied apace. If a parcel of drugs or an instrument left overnight had a spider's web on it in the morning, the doctor would patiently sally out and buy articles to replace them rather than disturb the spiders.

The Cost of the Epidemic of Small-pox at Montreal is likely to reach $5,000,000.

Congress of Naturalists and Physicians.—The fifty-eighth annual meeting of the Congress of Naturalists took place at Strassburg (September 18th to 23d). The number of communications presented to the various medical sections was very large.

An International Congress of Physicians Engaged in the Cure of Mental Diseases was opened at Antwerp on the 11th ult., under the presidency of M. Victor Desguin, President of the Belgian Society for Mental Diseases. The scope of the Congress comprises: 1. The bases of good International statistics concerning the mentally diseased; and 2, the relation between criminality and mental disease. An International Committee has been charged with the duty of determining the headings for the first of these subjects.

Photography in Medical Jurisprudence. — M. Gosse, at the recent French Congress, read a few notes on the importance of photography in medical jurisprudence. By placing a few drops of glycerine and water on the cornea of a dead man, the living expression is, he declares, reproduced, the exact position at the moment of death being represented in the photograph. This remarkable discovery at least deserves cautious consideration. It is hardly in accordance with current theories on the eye as an optical instrument, yet has been already suggested by other writers.

The New "Cancer Cure."—M. Landowsky, of Paris, has studied the Brazilian plant called by the natives alveloz, and believed by them to cure cancer. M. Landowsky believes this plant to be an euphorbia, discovered by Martin, and described by Muller under the name of *Euphorbia heterodoxa*. A preparation of its juice possesses the combined properties of a caustic and of papaïne. It promptly destroys the affected tissues layer by layer. At Pernambuco, after it has been well painted on the tumor, it is covered with a tobacco-leaf. M. Landowsky, in his communication at the Grenoble Congress, stated that, after applying it, he places over it a sublimate of vaseline and borax dressing.

M. Pasteur.—It is reported that M. Pasteur, who is now in the Jura, will, on his return to Paris, organize a system for protecting animals from rabies. He has arrived at a prophylactic method applicable to man and beast. Before leaving Paris, M. Pasteur applied the process to a boy who had been bitten on both thighs, both legs, and hands. The child is as yet in perfect health.

Rush Medical College, Chicago.—Rush College, of Chicago, by a recent action of its faculty, is to have, after the present college year, an additional condition of graduation. This consists of a course of practical instruction in the laboratory of physiology and pathology. The details of the course are not fully arranged, but it will include instruction in the management of the microscope, study of the histology of the simple tissues, and study of the urinary sediment.

A Library Lost by a Flaw in the Will.—By his will, made on October 27, 1881, the day before his death, Robert R. McIlvaine, of this city, bequeathed his collection of books and pamphlets to the Mayor of the city of New York, and the Presidents of the New York Academy of Medicine and the College of Physicians and Surgeons, as his trustees, for the purpose of establishing and maintaining an institution to be known as the McIlvaine Library. To maintain it he bequeathed to his Trustees all the residue of his estate—estimated at about $60,000—after the payment of certain legacies. The heirs have brought suit for the purpose of breaking the will, and the Court has decided that the provisions with regard to the library were invalid.

The Congress of Russian Physicians and Naturalists, which was to have been held this year at Kharkoff, has been postponed until August, 1886.

The International Congress of Pharmacy.—The sixth meeting of this Congress was held during the first week in September at Brussels. Measures were taken looking to the establishment in every country of a uniform course of study for pharmacological candidates, the graduates to receive a diploma, without which no one would be allowed to practise pharmacy. It was suggested also that the successful candidates should be entitled to the degree of Doctor of Pharmacy. The discussion of the question of an international pharmacopœia was postponed to the next Congress, in 1888.

Treatment of Mastitis by Rest.—Dr. W. F. Milroy, of Omaha, Neb., writes: "The issue of The Medical Record of August 22d contains a letter from Dr. P. A. Harris, entitled 'The Treatment of Mastitis by Rest and Compression.' That gentleman states that it is his object to 'review certain assertions' made by myself in an article published in The Record of August 8th. In the beginning of his letter he makes an unmistakable insinuation which is very damaging to my personal character. In The Record of September 5th Dr. Paul F. Mundé, very kindly and wholly unsolicited, comes to my aid, and I am released from the uncomfortable position in which Dr. Harris placed me. In order that the conclusion of Dr. Harris might be true, it was necessary that the case which I related in my paper should have been the first in which I used the treatment by rest, etc. In drawing this conclusion Dr. Harris says: 'It will be seen that Dr. Mundé's acceptance of my paper is dated June 11, 1884, and Dr. Milroy first employed his compression and rest under the service of Dr. Mundé, June 23d, of the same year.' The assertion that this was the

first case in which I made use of this plan of treatment, Dr. Harris has made entirely on his own responsibility. I have carefully re-read my paper and I find in it no trace of a clue as to whether the case in question was the first or last one of the thirteen to which I referred. In point of fact it was the eleventh. There are other points in the work of my 'reviewer,' upon which additional light is needed, but in consideration of the spirit in which he writes, I prefer to pursue the matter no further."

Complete List of Withdrawals from the Organization of the International Congress.—Out of the forty-two members of the Original Committee on Organization, there now remain only the following eight: Drs. Austin Flint, H. F. Campbell, R. A. Kinloch, N. S. Davis, Robert Battey, L. A. Sayre, Surgeon-General U. S. A., Surgeon-General U. S. N.

After the meeting of the American Medical Association in New Orleans, it was directed that the original committee of seven be enlarged by adding representatives from each State, Territory, etc., so as to make the total number forty-seven. This, known as the New Committee, met and organized permanently at Chicago. From this committee seven gentlemen have withdrawn: Drs. John S. Billings, John M. Browne, U. S. N.; Geo. J. Engelmann, I. Minis Hays, Christopher Johnson, *N. Senn, *T. F. Wood. From the rest of the general organization the following have withdrawn: Drs. A. Stillé, *H. H. Skillman, *John L. Atlee. *Oliver Wendell Holmes, Vice-Presidents; John H. Packard, Secretary-General.

The following is a list of the gentlemen who have withdrawn from the organization, in Sections, of the Congress as first planned at Chicago. The names marked thus * are of gentlemen appointed to fill vacancies, but who have declined the honor.

Section on Medical Education, Legislation, and Registration: Drs. S. E. Chaillé, President; Wm. Pepper, L. McL. Tiffany, Professor D. C. Gilman.

Section on Anatomy: Drs. Joseph Leidy, President; W. W. Keen, *G. E. De Schweinitz, Secretaries; Harrison Allen, Frank Baker, Thomas Dwight, F. L. Parker, C. T. Parks, T. L. Sabine, R. W. Shufeldt.

Physiology: Drs. John C. Dalton, President; H. P. Bowditch, J. F. Hibberd, M. Michel, H. G. Beyer, Wm. Lee, Henry Sewell, *J. H. Wythe, Vice-Presidents; John J. Mason, Council.

Pathology: Drs. F. Delafield, President; Wm. Pepper, Vice-President; Wm. H. Welch, Secretary; C. Fenger, R. H. Fitz, G. M. Sternberg, W. F. Whitney, *M. Longstreth.

Medicine: Drs. J. M. Da Costa, President; J. B. McCann, R. McSherry, *S. Weir Mitchell, Vice Presidents; Wm. Ogler, Secretary; S. C. Chew, T. F. Rochester, W. H. Geddings, W. W. Johnston, F. Minot, Beverley Robinson, J. T. Whittaker, *C. F. Folsom, *R. Bartholow, *F. T. Miles, *S. G. Webber.

Surgery: Drs. David W. Yandell, President; D. Hays Agnew, S. W. Gross, R. A. Kinloch, Vice-Presidents; John Ashhurst, Jr., D. W. Cheever, P. S. Connor, F. H. Gerrish, C. Johnston, T. M. Markoe, A. P. Smith, T. A. McGraw, J. R. Weist.

Gynecology: Drs. *Wm. T. Howard, *J. C. Reeve, *Albert H. Smith, *T. A. Reamy, H. P. C. Wilson, Vice-Presidents; Jas. R. Chadwick, Secretary; *Robt. P. Harris, *A. F. A. King, Theophilus Parvin, *E. S. Dunster, W. H. Baker, Wm. Goodell, A. R. Jackson, J. Taber Johnson, E. Van de Warker.

Ophthalmology: Drs. *E. Williams, President; H. D. Noyes, Wm. Thompson, Vice-Presidents; Swan M. Burnett, Secretary; H. Derby, E. G. Loring, W. W. Seely, Samuel Theobald, O. F. Wadsworth, H. F. Williams, *J. J. Chisolm, *B. E. Freyer.

Otology: Drs. Clarence J. Blake, President; H. N. Spencer, Vice-President; S. O. Richey, Secretary; J. O. Greene, G. Strawbridge, C. H. Burnett, E. H. Hazen

Dermatology and Syphilis: Drs. W. A Hardaway, President; L. A. Duhring, J. N. Hyde, I. C. White, Vice-Presidents; J. E. Atkinson, E. O. Wigglesworth, H. C. Yarrow, L. N. Denslow.

Laryngology (combined with Otology): Drs. John N. Mackenzie, President; F. I. Knight, Vice-President; D. Bryson Delavan, Secretary; E. C. Morgan, E. L. Shurley, *R. P. Lincoln.

Public and International Hygiene: Drs. Hosmer A. Johnson, President; A. L. Carroll, Vice-President; G. P. Conn, William H. Ford, J. H. Kidder, J. R. Smith, H. P. Wolcott.

Collective Investigation, etc.: Drs. E. M. Snow, Vice-President; Nathan Allen, James Tyson, *E. P. Hurd.

Military and Naval Surgery and Medicine: Drs. D. L. Huntington, President; Hunter McGuire, Vice-President; S. P. Moore, D. Bloodgood, J. H. Brinton, C. H. Martin, J. R. Tryon, A. A. Woodhull.

Practical and Experimental Therapeutics: Drs. Horatio C. Wood, President; Robert T. Edes, Vice-President; E. T. Reichert, Robert Meade Smith, Secretaries; R. Amory, H. M. Lyman, S. Nickols, D. Webster Prentiss, C. H. White, T. F. Wood, *G. M. Garland, *J. M. Flint.

Diseases of Children: Drs. Samuel C. Busey, President; F. Forcheimer, J. M. Keating, William Lee.

This makes a total of one hundred and forty-three vacancies made by the withdrawals.

In The Medical Record of July 11th, we gave a list of twenty-seven leading physicians of this city who were forced out of the organization by the introduction of an ethical issue. This makes a total of over one hundred and sixty.

The Florida Medical Association is to be congratulated upon displaying the good sense and self-denial illustrated in the following resolution, which was adopted at the last annual meeting: "*Resolved*, That it is the sense of the Florida Medical Association that it does not consist with the promotion of medical education and the best interests of the profession that any medical college should be instituted or encouraged in Florida at this time, and that the members of this Association will use their influence toward directing students of medicine to some of the many colleges of established reputation and reliability beyond the limits of this State."

Death of Professor Robin.—A cablegram from Paris announces the death of Charles Philippe Robin, a well-known physician and scientist, and member of the French Senate. He was sixty-four years of age.

Evolution and Obstetrics.—Dr. H. G. Anderson, of La Moure, Dakota, reports that out of eighteen births in his practice this summer seventeen have been girls. The doctor, says the St. Paul *Globe*, is a scientist and insists that it is not an accident, but the intelligent provision of nature to satisfy local demand. That is a very new region, in which the male settlers greatly predominate. Such disparity, it is alleged, is never found in the older towns, where the sexes are nearly equal. The La Moure instance is not an isolated one.

The Results of the Sanitary Inspection of Food in this city during the past three months are given as follows: During that time there were 1,169 milk inspections made, 1,356 specimens of milk examined, 617 quarts of impure milk were destroyed, and 22 persons were arrested for selling adulterated milk. The fruit, fish, and meat inspectors inspected 353 vessels, 2,402 stores, 1,895 licensed vendors' wagons, 168 markets, and 2,399 stands, and seized and condemned 37,905 pounds of canned goods, 109,144 pounds of meat, 43,981 pounds of fish, 7,169 pounds of cheese, 472 barrels, 197 crates, 387 bushels, and 187 baskets of apples, 1,740 pineapples, 9,000 bananas, 2,651 cocoanuts, 311 egg-plants, 20 boxes of lemons, 408 barrels of musk-melons, 13,706 water-melons, 5 crates of oranges, 1,000 barrels of pears, 900 baskets of peaches, 30 bushels of plums, 23 barrels of potatoes, 100 crates of tomatoes, 1 barrel of turnips, 21 tons of miscellaneous fruits and vegetables, 4 tubs of butter, 5 boxes of eggs, and 2 barrels of pickles. The total number of fruit inspections was 7,313; 1,289 violations of the sanitary code were discovered, and 483 inspections of offensive trades were made. The entire number of inspections of all kinds was 15,112. Dr. Cyrus Edson is entitled to much credit for his energetic and successful work.

The American Public Health Association will hold its thirteenth annual meeting in Washington, D. C., beginning December 8th. It is rare that a national organization so soon achieves the membership and strength of the Association in question. There is every prospect of a large and useful meeting. Dr. Smith Townsend is chairman of the Committee on Arrrangements. The headquarters of the Association will be at Willard's Hotel.

The Results of creating "Legal Doctors" in Indiana are given in the *Indiana Medical Journal*. In Marion County 275 out of the 470 physicians have registered. Of those registered, 195 have diplomas from regular medical colleges, 78 are graduates of irregular institutions or take advantage of the ten or three years' clause. The law has shown up the educational history of the quacks; it has, on the other hand, put these quacks on a legal footing.

Longevity of German Professors.—It is said that there are at present at the various German universities no fewer than 157 professors between the ages of seventy and ninety. Of these 122 deliver their lectures as usual. The oldest is the veteran Von Ranke, the historian, who is now in his ninetieth year, but is not considered fully equal in vigor, memory, and other faculties to Professor Elvenich, who is thirty-nine days his junior.

Obituary.

DR. JOHN LIGHT ATLEE.,

LANCASTER, PA.

The death of Dr. John Light Atlee, at the venerable age of eighty-six, removes one of America's most distinguished surgeons, and one who assisted to create a new epoch in surgery.

Dr. Atlee was born in Lancaster on November 2, 1799, and was the son of Colonel William Pitt Atlee, a Revolutionary officer. He was educated in Lancaster and Philadelphia, studied medicine under Dr. Samuel Humes; and graduated from the University of Pennsylvania in Philadelphia in 1820. After graduating he returned to Lancaster and began the practice of medicine. He soon became very successful in surgical operations, and in this branch of his profession his reputation was very high. Dr. Atlee's operation for double ovariotomy in 1843 was the first in the history of medicine, and the patient is still living in Lancaster in good health. He was one of the founders of the Lancaster City and County Medical Society and twice served as its President. In 1848 he assisted in organizing the Pennsylvania State Medical Society, and became its President in 1857. He was also one of the organizers of the American Medical Association in Philadelphia in 1857, was elected Vice-President in 1865, and President in 1882. He was Professor of Anatomy and Physiology in Franklin and Marshall College for many years; was School Director for forty years; was President of the Board of Trustees of the Pennsylvania State Lunatic Asylum at Harrisburg; was Associate Member of the College of Physicians of Philadelphia; was elected Honorary Fellow of the American Gynecological Society in 1877, and was trustee of numerous public institutions. He was a contributor to many medicial periodicals.

Reviews and Notices.

The Use of the Microscope in Clinical and Pathological Examinations. By Dr. Carl Friedlander; translated by Henry C. Coe, M.D. 8vo., pp. 195. New York: D. Appleton & Co. 1885.

Much good has been done in placing this little work in the hands of the profession. The technique of preparing, cutting, and staining specimens is given at some length; also rules for the examination of the various bodily fluids in both health and disease. The use of the microscope with high powers, immersion lenses, and other accessories, is explained very clearly. It is a very readable volume, even for those not engaged in actual laboratory work. A chromo-lithograph shows the various forms of disease-germs which have been definitely isolated.

Reports of State Boards of Health: Of New Hampshire for the year ending April 30, 1885; of Tennessee, October, 1880, to December, 1884.

Both of these volumes are published in an attractive form, and though primarily of interest to physicians residing in the States named, they yet contain articles relating to epidemics, etc., that cannot fail to be of interest to those interested in our national medical history.

Mind-reading and Beyond. By William A. Hovey. Boston: Lea & Shepard. New York: Charles T. Dillingham. 1885. Pp. 201.

Mr. Hovey presents to us in a succinct form the work of the Society of Psychical Research (London), regarding the subjects of mind-reading, thought-transference, etc. Mr. Hovey and his school are well intentioned, but are, we fear, in pursuit of a will-o'-wisp. However, those who like such sport will be interested in his book.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 1, 1885.

A. Jacobi, M.D., President, in the Chair.

The Library Committee, Dr. John C. Peters, Secretary, reported that since the last meeting there had been donated to the library seven hundred and one bound volumes.

The Statistical Secretary, Dr. Francis V. White, announced the death of William C. Hunter, M.D., and the President appointed Dr. E. H. Janes memorialist.

The President then delivered an address, which appeared in The Record for October 3d.

OBSCURE CASES OF WEAK HEART.

Dr. R. Van Santvoord read a paper on the above subject, which will be published in The Record.

Dr. J. C. Peters referred to a case of weak heart occurring in a man, sixty years of age, of regular habits, and in apparent health, and brought on, probably, by the error in diet, consisting of the use of prepared foods and condensed milk. He was a bachelor. The result was indigestion and deficient supply of nutrition. When he first saw the man, there was evidence of slight congestion of both lungs, exceedingly weak pulse and action of the heart, dyspnœa, albumen in the urine, evidently of recent occurrence, and for ten or twelve days he was in a desperate condition.

With reference to remedies for feeble cardiac action, Dr. Peters had found nux vomica to be more reliable than digitalis. He had seen several cases of death with weak heart in pneumonia, and formerly thought the fatal termination was due to the formation of blood-clot in the right ventricle, but he had come to regard overstrain of the heart as the real cause of death.

Dr. L. Weber spoke of weak heart, with or without organic disease, where there may be some dilatation and sometimes more or less fatty degeneration. In these rather chronic cases, as stated by the author of the paper, he had not seen any good effect from the use of caffeine (hydrobromate). He had, however, seen the usual results from the use of digitalis—infusion of the English leaves or Squibb's fluid extract.

In the acute cases, such as met with after typhoid fever, scarlet fever, etc., he had given from two to six grains of hydrobromate of caffeine, three times daily, in addition to the usual tonics, and he had thought that the patients did much better than with the use of tonics alone.

Dr. E. Darwin Hudson said that the proper recognition of the nervous connections and conditions of normal cardiac action, associated with a proper knowledge of what might exert a toxic influence on the nervous centres, gave the physician landmarks from which to start in the differential diagnosis of cardiac diseases and conditions. The careful physician first eliminates organic diseases, and then all the disturbing influences, such as those which come from disorders of the kidneys, the liver, the stomach, etc. Failing in all these directions to detect any cause, he suspected the existence of some obscure organic change not readily recognizable.

Dr. J. P. Garrish mentioned a remedy used by the late Dr. Valentine Mott in cases of feeble cardiac action; that is, tincture of digitalis and tincture of stramonium, equal parts, administered in ten-drop doses three times a day.

Dr. Andrew H. Smith referred to the double function of digitalis: *first*, to affect cardiac action, and, *second* to promote cardiac nutrition. Small doses are administered with the hope of improving the nutrition of the muscular structure.

Dr. J. H. Fruitnight referred to cases in which he had used digitalis, convallaria, etc., without benefit, and in which the use of the tincture of the night-blooming cereus, in doses of from three to ten minums, had served an excellent purpose.

Dr. Van Santvoord regarded Dr. Peters' case as instructive and one to which he had referred in a general way, namely, the development of general cardiac failure, but not manifesting itself until some special strain is placed on the organ. In the case mentioned, there was a condition of the lungs which gave rise to strain on the right side of the heart, but probably not sufficient to be serious if the heart had not already been affected.

With Dr. Hudson he agreed that all these cases could be analyzed by careful study and exclusion; but in two of the cases which he had reported the patients were examined by exceedingly competent men, who had said that the heart was entirely healthy, and by one who examined again after the sphygmographic tracings had been taken, and still said that the organ was not diseased.

AN OLD CLINICAL THERMOMETER.

The President presented a clinical thermometer, received through Dr. George F. Shrady, from Dr. Samuel Francis, of Newport, R. I., it having been used by his father, Dr. John W. Francis, one of the founders of the New York Academy of Medicine. It seemed quite probable that the instrument was made as early as 1830.

On motion by Dr. Agnew, the gift was accepted, with the thanks of the Academy to the donor.

The President also presented a beautiful portrait of

THE LATE CHARLES M. ALLIN,

donated by the widow of the deceased.

On motion by Dr. E. Eliot, it was accepted, with the thanks of the Academy.

The Academy then adjourned.

THE SURGICAL SOCIETY OF PARIS.

Stated Meeting, July 22, 1885.

M. Horteloup, President, in the Chair.

(Special Report for The Medical Record.)

M. Segond read a short communication upon the

TREATMENT OF ABSCESSES OF THE PROSTATE.

He maintained that the incision of abscesses of this gland through the rectum was attended with many disadvantages. It was, in the first place, usually insufficient to permit of thorough drainage and evacuation of the pus; there was the danger of hemorrhage; if an opening into the urethra should also occur there would result an urethro-rectal fistula, a very difficult matter to cure; and finally, in this mode of operating, it was impossible to obtain antisepsis. All these difficulties, the writer maintained, were obviated by opening the abscess through a perineal section.

M. Reclus agreed with the author of the paper in his preference for the external operation.

M. Pozzi related a case of

ENCYSTED CALCULUS

of the bladder. The stone was carried for a long time without discomfort, but becoming dislodged, gave rise very suddenly to acute symptoms. The speaker exhibited the calculus to the members of the Society.

M. Lucas-Championnière related a case of

HYDATID CYST OF THE ANTERIOR BORDER OF THE LIVER.

The patient was a young woman, aged twenty-two, who presented a tumor of rapid growth situated in the right side. It was apparently a tumor of the kidney, but was accompanied by no urinary troubles, and was painless. An incision was made in the median line of the abdomen, when the tumor was found to be attached by a pedicle, about two inches in thickness, to the anterior border of the liver; it had also formed adhesions to the

omentum and to a fold of intestine. The kidney was small but healthy, and pushed back behind the liver. The tumor was seen to be a hydatid cyst with very thick walls, in several parts of which were small points of suppuration. It was removed after a somewhat laborious dissection.

The same speaker also reported a case of

TOTAL EXTIRPATION OF THE RIGHT KIDNEY.

The patient was a woman, aged forty, who was suffering from severe pain and vomiting, and presented a large tumor in the right side. This had grown very rapidly, and, when punctured, gave exit to about twenty-four ounces of pus. An exploratory incision showed that the kidney was the seat of the lesion. Pus now began to be passed in the urine. A few days later the diseased organ was removed through an incision, made from the false ribs obliquely toward the iliac fossa, avoiding the peritoneum. The operation was tedious and difficult, but was followed by excellent results. The wound healed by first intention, and the patient was able to get up on the ninth day. The kidney was of an enormous size, with greatly thinned cortex, but with a thickened capsule.

M. GILLETTE then read a paper on

TUMORS OF THE KIDNEY IN THE MALE.

These were not common, the speaker said, yet through the labors of MM. Horteloup and Poirier, who had chosen this as the subject of their theses, we were now in possession of quite a number of facts of this nature. The author exhibited the cast of a fibrous carcinoma of the kidney, which he had recently removed from a man. The tumor had existed for six years, but the patient would not have thought of having it removed, so little annoyance did it give him, were it not for an oozing of blood and serum which took place from it. Fibrous carcinoma, the author stated, was one of the most common varieties of renal tumor in the male subject. The disease was apt to return, indeed, in man as it was in woman, but it was of a less malignant nature. The characters which distinguished renal tumors in man from those in women were less tenderness, less radiation of the pain, and less tendency to glandular involvement. But, although the symptoms were often apparently of such little moment, the tumors should be removed as early as possible, for they were undeniably malignant.

M. GUERMONPREZ related a case of

TUMOR OF THE ANTITRAGUS

which he had removed from a patient not long before.

M. DUBAR sent a communication concerning a

CONGENITAL CYST OF THE NECK.

The patient was a little girl, nine years of age, who had had a small tumor, the size of a hazel-nut, removed from the neck by means of an injection of chloride of zinc. Six months later the tumor reappeared and was extirpated, and three months afterward it again appeared and was again removed by the knife. This time the cure seemed to be permanent. Microscopical examination showed that the tumor was formed of a sac-wall covered with epithelium, from the under surface of which epithelial prolongations passed down into the subjacent layers of the cutis.

M. RECLUS said that he had had a similar case, in which, however, a fourth relapse had occurred.

M. ANGER thought that the insuccess of cauterizations with chloride of zinc was due to the presence of a membrane lining the sac, and similar to the mucous membrane.

M. TILLAUX said that it was often very difficult to cure these cysts, and attempts at cure were not infrequently followed by the formation of fistulous tracts.

M. POZZI said that these fistulous tracts should be dissected out with great care, and he thought the operation might be facilitated by the injection of some coagulable substance into the sinuses.

M. MONOD thought that the introduction of a fine sound would make the operation less difficult.

The Society then adjourned.

ACADEMY OF MEDICINE OF PARIS.

Stated Meeting, August 18, 1885.

M. BERGERON, PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

M. LE ROY DE MÉRICOURT read a letter which Dr. Solari, of Marseilles, had written to him in regard to the

CHOLERA EPIDEMICS OF 1884 AND 1885.

The writer said that gastro-intestinal troubles had not existed in any notable degree in Marseilles and Toulon prior to the arrival of the ship Sarthe in the latter place, in June, 1884, but since that time they had been prevalent, even during the winter months, and had increased in proportion as the weather became warmer in the spring. The cholera had been imported from the Tonquin delta, where it was endemic, as it was in all the deltas of Southern Asia. It was true that the sanitary condition of these two cities was bad, but it had been so for many years, yet cholera was not known there until it was imported from the East. It could not originate there, but found a ready field for its development upon its arrival. Now that there was to be ready communication between France and Tonquin, there was no doubt that cholera would be a frequent visitor unless the authorities should institute efficacious sanitary measures.

M. BROUARDEL maintained that Dr. Solari's statements were incorrect in nearly every particular. He denied that the disease had been imported by the transport Sarthe and said that it was not endemic in the Tonquin delta. The municipal authorities of Marseilles were not to blame for the insalubrity of the city, for they had done all they could, but the law was defective in not giving sufficient powers to the health commissioners.

M. FÉRÉOL related a case of

CHROMIDROSIS,

which had been seen in consultation with Dr. Sabourin. The patient was a young woman, about twenty years of age, who had had several violent hysterical attacks. She had convulsions and neuralgia, and almost incessant vomiting. One of the ovaries was tender on pressure. A cure was obtained in the course of time by the application of ice over the ovary and the internal administration of ice and brandy. About two months later, while the patient was in M. Féréol's office, and sitting in a strong light, he noticed on her lower eyelids a bluish tint which gradually became more pronounced. On being spoken to about it she said that she had noticed it for the past two months, and that it was a great annoyance to her. Taking her handkerchief she rubbed the skin briskly for a few seconds, transferring the color from her face to the linen. The patient remained about twenty minutes in the office talking about her trouble, and, as she left, Dr. Féréol noticed that the blue tint was again becoming visible. There was no perspiration, nor could any granules be seen, even with a magnifying-glass, but it seemed to be a uniform staining of the skin. The same phenomenon was present on the chest in the intermammary groove and in the axillæ.

M. JULES GUÉRIN then read a paper upon

SUBCUTANEOUS SYNDESMOTOMY IN THE TREATMENT OF CLUB-FOOT.

He said that in a case of talipes in an infant or an adolescent which had resisted tenotomy, success might be attained by the division of certain of the ligaments.

In over a thousand cases of club-foot he had not met with one which was not amenable to treatment by tenotomy and syndesmotomy, combined with manipulation and the adjustment of suitable mechanical apparatus. For the correction of equino-varus he practised division of the internal lateral ligament of the tibio-tarsal articulation and of the internal calcaneo-scaphoid ligament; and in talipes varus the inferior calcaneo-cuboid ligament. There was no danger if the subcutaneous operation was performed, and if the cutaneous wound was made as far as possible from the point of division of the ligament. The subsequent manipulations, without which no cure could be effected, were not to be attempted until cicatrization of the external wound had taken place. The speaker exhibited some plaster casts showing the good results obtained by this method.

M. Bouley said that he had had an opportunity of witnessing the success of M. Guérin's operation. A boy, who before the operation could scarcely walk, and who stepped upon the dorsum of the foot, was able, a few weeks after syndesmotomy was performed, to walk naturally and easily with the sole of the foot resting squarely upon the ground.

M. Gibier then read a paper entitled

EXPERIMENTAL RESEARCHES ON CHOLERA,

which embodied an account of the labors undertaken by himself and Dr. Van Ermengen, of Brussels.

M. De Villiers communicated the results of observations upon the

PRESENT EPIDEMIC OF CHOLERA

in the South of France, which he had made during a recent tour of the infected districts. This present epidemic, unlike that of last year, had been preceded for some time —the entire winter indeed—by numerous gastro-intestinal disorders.

M. Léon Lallemand, member of the Society of Political Economy, read a paper entitled

A CHAPTER IN THE HISTORY OF INFANT ABANDONMENT.

The paper dealt principally with the statistics of mortality of the foundlings in the *maison de la couche*, at Paris, during the seventeenth and eighteenth centuries.

The Academy then adjourned.

THE BERLIN SOCIETY OF INTERNAL MEDICINE.

Stated Meeting, June 15, 1885.

Herr Leyden, President, in the Chair.

(Special Report for The Medical Record.)

The President announced that the Imperial Normal-Standard Commission had been asked to undertake the work of testing thermometers, and at his suggestion it was voted to send a delegate from the Society to attend the next meeting, at which this subject would be considered.

Herr Becher presented a case of

ECHINOCOCCUS OF THE LIVER.

The patient, a boy, nine years old, had always been healthy, with the exception of a severe attack of pleurisy through which he passed three years ago. Five weeks ago a tumor was noticed over the liver in the right mamillary line. It was about the size of half a Borsdorfer apple, with tense walls through which fluctuation was distinctly perceptible, and painless on pressure. The boy was in the habit of playing with dogs, and allowed them to lick his face and hands, and it was probable that the tape-worm eggs were transported by the dogs' tongues to the boy's hand, and thence gained admittance into the stomach. The principal interest in the case centred upon the question of treatment. Formerly surgeons were loath to operate in such cases, and treated them more on an expectant plan. In many instances a spontaneous cure took place, but not infrequently also death resulted from peritonitis or rupture of the cysts. The present tumor had increased one-quarter in size in the past five weeks, and it therefore seemed inadvisable to delay. The speaker had determined to operate, and he would inform the Society of the result at some subsequent meeting.

Herr G. Behrend asked whether the urticaria wheals, which were visible here and there on the boy's body, were there before, and whether they had been more numerous than they were now. He said that urticaria was not uncommonly seen with hydatids, especially after rupture of the sac and absorption of its contents.

Herr Becher replied that he thought the wheals were the effect of the cold water compresses which the patient had worn.

Herr Litten bore witness to the truth of the fact alleged by Herr Behrend. He had himself observed a similar occurrence in Frerich's clinic.

Herr Köbner exhibited a case of

RHINO-PHARYNGEAL SCLEROMA.

The patient was a strongly-built man, forty-six years of age, a Polish wheelwright. His nose was enlarged, of a deep-red color, hard to the touch, and the nostrils were stopped up with a dark-red, lumpy, scabby looking mass. When this was removed the nasal cavities were seen to be completely filled, to such an extent that even air could not pass through, with an immense number of small growths attached to the septum, alæ, and floor. These growths were comparatively soft, and when cut were painful and bled freely. The velum of the palate was covered with erosions, and some deep, but small ulcers, and in some parts, especially on the right side, were little tumors of an almost ivory consistence. The posterior portion of the velum was contracted by cicatricial tissue, and attached to the posterior wall of the pharynx. Where the velum passed to the anterior palatine arches there was a shining, yellowish, white growth. The hard palate was normal, as were also the gums and the tongue. The larynx and trachea were not involved, and the patient was perfectly well in every other respect, and gave no evidence of syphilis. He said that when twenty years old he had had gonorrhœa and epididymitis, and later a chancre which had healed rapidly without any subsequent symptoms of constitutional trouble. He had always been subject, as a boy, to nose-bleed. He first noticed that something was wrong ten years ago, when he began to be troubled with the accumulation of large quantities of dried mucus in the left nostril. Six months later there was a profuse secretion of mucus, and he noticed that his voice had a nasal twang. At the same time he felt a burning in the palate when drinking spirituous liquors or smoking. Two years after this the right nostril was affected in the same way. The patient had taken iodide of potassium, and had had inunctions of mercury, but with no result.

Herr Jarowitz related a case of

TUMOR OF THE CEREBRUM.

The growth was the size of a hen's egg, situated in the right frontal convolution. The first symptoms had appeared suddenly five weeks before death, and were those of meningitis, dizziness, intense headache and vomiting. The paralytic symptoms were an indication for the diagnosis, as regards location of the tumor, which was confirmed at the autopsy. The patient died suddenly in coma.

Herr Lassar exhibited a case of

ERYTHEMA EXUDATIVUM.

The patient was a man, sixty-five years of age, who had previously been in good health. His body was covered with bright red, in some portions livid spots, with more or less elevated base, which showed a slight tendency to symmetry on the two sides of the body. In many parts there were sub-epidermal exudations of fluid,

sometimes going on to the formation of large blisters. The case was one of exudative erythema, or

EXUDATIVE PHLYCTENOID HERPES.

The speaker had now five similar cases under treatment, not all, however, as severe as this. This patient had no fever, but in one of the cases there was a considerable elevation of temperature. The origin of the inflammation was to be referred to irritation from a plaster containing turpentine which the patient had applied for the relief of a severe colic.

HERR A. FRÄNKEL then read an exhaustive paper on

DUODENAL ANCHYLOSTOMA.

The disease, which had been known for a long time, was thought, until very recently, to be confined to the tropical regions of Asia, Africa, and America, the only exception being its existence in Italy. Griesinger was the first to recognize the parasitic nature of the affection, having discovered the anchylostoma during his study of the disease in Egypt. Professor Perroncito found the same parasite to be the cause of the anæmia from which the laborers in the St. Gotthard Tunnel suffered, and also of miners' anæmia. There is still another affection,

BRICK-MAKERS' ANÆMIA,

which has long been recognized, and which was supposed to be a form of essential anæmia. This has now been shown to be due to the presence of the peculiar parasite, and the speaker thought it not improbable that the same cause might be concerned in the production of pernicious anæmia.

The parasite is a round worm, varying in length from six to eighteen millimetres (one-fourth to three-fourths of an inch), the females being the longer. The mouth is characteristic; it is provided with strong teeth, by means of which the parasite attaches itself to the wall of the intestine and opens a blood-vessel. The eggs of the worm are found in great numbers in the intestine and pass off with the fæces. They are not further developed in the intestine; but outside, if kept in a hatching-oven at a temperature of 76° to 82° F., the larva is hatched out in forty-eight hours. The process is again arrested and the larva develops into the anchylostoma only when in the body of its host. The larvæ are usually taken in with the drinking-water.

This disease is manifested, clinically, by severe gastric disturbances and by anæmia. The latter is caused partly by the direct loss of blood and partly by the interference with normal digestion. The patients become gradually paler and suffer from colic, vomiting, and diarrhœa. Examination of the blood shows a decrease in the proportion of red globules to the extent even of one-fifth of their entire number.

THE TREATMENT OF ANCHYLOSTOMA DUODENALE

consists, of course, in the removal of the parasite. The most effective means, though not always a perfectly safe one, is the administration of one-half to one ounce doses of the ethereal extract of male fern. Thymol in powder, in doses of one-half to two and a half drachms per diem, is also effective. A safer drug, which has found favor in Brazil, is doliarina. This is a mixture of the juice of the *ficus doliaria* with iron and aromatic powder. The daily dose is one drachm. After the expulsion of the worms, tonics and a nourishing diet are necessary.

The Society then adjourned.

TEN CENTS' WORTH.—We have rarely seen a more striking illustration of dewy freshness, or of fine appreciation of the value of medical services than is shown in the following letter, forwarded to us by Dr. E. H. Greene, of Atlanta, Ga.: "Dr E. H. Greene Dear Sir Please send me a medicine that will cured my diseas: send .10ct worth and as soon as possible. my diseas is the "Clap.' send carfully to S. F. F——." Five two-cent stamps were enclosed.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE SHORTCOMINGS IN LONDON MEDICAL TEACHING—FACILITIES FOR MEDICAL STUDY TO MEDICAL VISITORS—GENERAL AND SPECIAL HOSPITALS.

LONDON, September 22, 1885.

A GREAT deal has been said about the shortcomings of London as a medical centre. I must confess there is a good deal of truth in much of what has been said. Considering the vast size of this metropolis and the enormous amount of clinical material available, London medical teaching is not what it ought to be—not what it might be. This is partly due to the size of London and the indiscriminate way, so to speak, in which its medical institutions are scattered over it. A foreigner visiting London will find no such concentration of clinical material as at Vienna, where in the vast Krankenhaus he will find a conglomeration of almost all the diseases under the sun—at any rate of those under the sun of Austria. I may also add, parenthetically, that he will also not find in London such absolute disregard of patients' feelings and modesty as he will see displayed at Vienna. In London he will have to rush about from hospital to hospital if he wishes to see all there is to see, and see some of the practice of different schools. As elsewhere, he will also find that not every man who holds an important hospital appointment makes the best use of it for teaching purposes. Some cannot teach; others will not. Of those who both can and will, many are too busy with private practice to give much time to clinical teaching. They pay a hurried visit to their wards, and perhaps when they have seen half their patients a glance at the clock shows them that they are due at some private appointment, and, with just a glance at the more important of the remaining patients, off they go. Private practice is much more lucrative than teaching, and when it begins to come apace it is not to be wondered at that it should be set first. Many men, too, who would make excellent teachers in the wards have to drudge for years in the out-patient department before they get charge of beds. They spend their best energies and the best years of their lives in prescribing for chronic bronchitis, ulcerated legs, and so forth. If a man is a good teacher and naturally fond of teaching, ten years among out-patients is likely to dampen his zest a little. Then, again, the rule which requires a physician or surgeon to retire from his hospital appointment after twenty years, although a good rule on the whole, yet sometimes deprives our medical schools of some of their best teachers. Jenner, Walshe, and Hutchinson may be instanced as examples.

Still there is something to be seen in London, and a medical visitor may see a good deal if he uses his time aright. I will give a few hints which may be useful to American medical men visiting London.

First of all, as to the general hospitals, and more particularly those with medical schools attached. In all of these there is regular clinical teaching in medicine, surgery, and the various specialties, though for the latter some of the special hospitals may with advantage be visited. The best way of seeing the working arrangements of a London hospital is to make an early morning call, and for the medical visitor to send in his card to the house-surgeon or house-physician on duty. They will usually be pleased to give him any information in their power, and will probably allow him to accompany them a few times in their morning visit to the wards. He will thus see much more of the hospital than if he only accompanies the physician or surgeon in his rounds. In the surgical wards he will see the dressers at work, and if the house-surgeon is not very busy he will generally find him both able and willing to give him information about

the cases and the various methods of treatment employed. He can then accompany the physicians and surgeons in their rounds. At the London Hospital an American graduate can hold a dressership or clerkship for a few months, if he wishes, on payment of a small fee.

Antiseptic practice may now be seen at all the general hospitals, but a visit should certainly be paid to Sir Joseph Lister's clinic at King's College Hospital.

It is in studying the various specialties that the greatest drawback is felt. Although almost all our general hospitals now have special departments—in many of which there is excellent teaching—yet a specialist visiting London would naturally wish also to visit some of the special hospitals. Then will he find his troubles commence, and he will sigh for the centralization met with in Vienna. If he is interested in more than one specialty —or even if he wish to attend two or more institutions devoted to the same specialty—he will find a good deal of time consumed in getting from one part of London to another. He will often also be disappointed by finding that two clinics which he wishes to attend are both held at the same hour. Still, by a judicious planning out of the day's work it is quite possible to go about and see a good deal, and the expenditure of a few shillings a day in hansom cabs will enable the visitor to get over the ground very quickly. I may remark *en passant* that for short distances a hansom cab is by far the most rapid means of transit, even more so than the Metropolitan Railway, unless the traveller is close to a station of the latter. For eye diseases the practice of the Royal Ophthalmic Hospital in Moorfields (City) should be watched. It is decidedly the largest ophthalmic clinic in London, and systematic instruction is given. Patients are seen early in the morning, so it can be attended without missing the afternoon clinics elsewhere. Those who are located at the West End will find a good deal to see at the Westminster Ophthalmic Hospital (Charing Cross), where the clinic is in the afternoon. The largest clinic in skin diseases is at the Blackfriars Hospital (Stamford Street), though there are several others. Laryngeal diseases may be studied at the Golden Square Hospital (which is the oldest), also at the Central Throat and Ear Hospital (Gray's Inn Road). There is an ear hospital in Soho. There are two orthopædic hospitals at the West End and one in the city. Dental practice can be well seen at the Dental Hospital in Leicester Square. There are several hospitals for women, of which those in Soho Square and at Chelsea are the most worthy of a visit. The gynecologist would do well also to visit Dr. Mathews Duncan's clinic at St. Bartholomew's Hospital, and Dr. Playfair's at King's College Hospital, the latter being near the Law Courts. Antiseptic midwifery may be seen in operation at some lying-in hospitals, viz., Queen Charlotte's (in the Marylebone Road), the British (in Endell Street, Long Acre), and the General (York Road, Lambeth). At either of these he will find the resident medical officer or matron ready to give him any information he may desire. We have, however, in London no institution resembling the Rotunda Hospital in Dublin, where clinical midwifery may be studied fully and systematically. We have also no clinics where venereal diseases are systematically considered, though there is a small Lock Hospital for men in Soho, and a much larger one for women at Westbourne Green (Harrow Road). As the Contagious Diseases Acts are not now in force the syphilographer will not find much of a field for study, even in those towns to which they applied, and to the hospitals of which lock wards are attached. It is perhaps needful to remark that the acts never were in force in London.

The medical visitor who wishes to see something of British practice, and has not much time to spare, will do well not to be too ambitious. By confining his attention mainly to one or two hospitals he will see a great deal more in a short time than by frittering away his time between half-a-dozen. He may, it is true, find time to pay a flying visit to a good many of our medical institutions, but to gain a real insight into British practice he will do well to confine his attention mainly to a few. Which these should be must depend on his tastes and partly on his location in London. If he is not a specialist he will do well not to devote too much time in going the round of the special hospitals, but to content himself with attending the special departments of one of the general hospitals. In many of them he will see good practice and find the physician or surgeon in charge both able and eager to teach. The neurologist, though, should scarcely omit to pay a few visits to the National Hospital for the Paralyzed and Epileptic in Queen Square. The Brompton Hospital for Consumptives, too, is well worthy of being inspected, whether the visitor be interested in chest diseases or not. (So is that at Ventnor, Isle of Wight, where every patient has a separate bedroom.) The Cancer Hospital and the Chelsea Hospital for Women are both near, and might be seen on the same day. No medical visitor to London should fail to visit St. Thomas' Hospital. Architecturally, if for nothing else, it should command attention. I need scarcely say it is also an important centre of clinical study. Guy's, The London (which has the largest number of beds of any hospital in Great Britain), and St. Bartholomew's should all be seen once at least. As specimens of model parochial infirmaries those of St. George's, Hanover Square (at Fulham), and of Marylebone (at Notting Hill) may be visited.

I presume no medical visitor to London would fail to visit the College of Surgeons and inspect its library and museum. Many hours might be spent in the latter. The museums, too, of many of the hospitals are well deserving of attention. Guy's Hospital Museum contains a very valuable and unique collection of wax models.

THE GRAPE AS A FOOD AND MEDICINE.

To the Editor of The Medical Record.

Sir: In view of the fact that the administration of drugs is becoming every day more and more the opprobrium of medicine, and now that the grape season is at hand, I desire, through the medium of your excellent journal, to call the attention of the profession to the physiological and curative virtues of grapes when employed as a medicament.

I may remark, at the outset, that I have, in connection with the subject, figured several times in the somewhat anomalous character of a physician taking his own prescription, and have, moreover, never felt the force of the Gallic facetiousness that objects to taking wine in the form of pills.

The grape cure is a therapeutic means that seems to be very little known, not only in the United States, but among English-speaking people generally. As far as my limited time will allow inquiring into the literature of the subject, the English references appear to be extremely scanty. Nevertheless, the subject has a history and a bibliography of its own, ancient, mediæval, and modern, extending from the time of Dioscorides and Pliny to recent Spanish, Italian, French, and even modern Greek memoirs on ampelotherapeutics. It is, however, to German literature that one must look for the most intelligent and interesting accounts, which are to be found in the numerous monographs published in the last few decades. Some years ago my attention having been directed to the subject through one of the latter sources of information, I shortly afterward had an opportunity to prove some of the results of the grape cure by personal experience. Arriving in Cadiz after a long voyage and the monotonous diet of a sailing ship, and my system being considerably below par, I determined to try for a time a diet consisting almost exclusively of grapes, which at the time were plentiful in the sherry region of Andalusia. The result was rapid re-establishment of all the bodily functions, with a sense of well-being, and a feeling of more

than ordinary strength and agility. Here, however, arose a difficulty in distinguishing the results of the effect of the grapes from the results of the regimen, the other dietetic adjuncts of the cure, and the change of surroundings.

But the advocates of the grape cure having made satisfactory observations on the action of grapes, independently of the dietetic and hygienic adjuncts of the cure, and having studied the grapes chemically as well as clinically, I was prompted, while in San Francisco, to resort to the grape cure for the second time and under circumstances almost analagous to those detailed in the first instance. The result being highly satisfactory, I recommended the cure to several other persons who were much run down from overwork and bad diet, and I soon had the satisfaction to see a rapid gain both in their weight and appetite.

The quantity of grapes that one may eat with impunity is something astonishing. Most persons at the European uval stations consume from three to six kilos. daily. I have, however, greatly exceeded this quantity while sojourning on a California grape ranche. Grapes constitute a perfect nutriment which encloses in remarkable proportions the nitrogenous, albuminoid, and respiratory principles indispensable to a good alimentation; and the grape cure is an essentially alimentary regimen in which the principles of a vegetable nature predominate over those of an animal nature. Doubtless the knowledge of the alimentary properties of grapes derived from the fact that certain migratory birds fatten on them, and that the flesh of young foxes after a grape diet becomes palatable, may have had more to do with the employment of grapes as a medicament than any knowledge deduced from their chemical study. According to the analysis of Henry and Chevallier, a striking anology exists between the juice of grapes and woman's milk. These chemists find in 100 parts as follows:

	Human milk.	Grape juice.
Albuminoid and nitrogenous matters	1.5	1.7
Sugar, gum, etc.	11.0	12 to 20.0
Mineral substances	0.4	1.3
Water	87.0	75 to 83.0

It is further consistent with the chemical deductions of the properties of grapes that cures analogous to those obtained by natural mineral waters may be accomplished with great success. In Germany, the grape cure is looked upon as a necessary and indispensable complement to the thermo-mineral treatment, and it is customary to send patients after such treatment to places like Bingen, Durkheim, Vevay, Aigle, and Celles-les-Bains. At certain of these uval stations patients are recommended to drink two or three glasses of the freshly expressed juice; and they are also provided with baths for persons who want to be plunged into the mash of the grapes while it is in a state of fermentation. These baths, much in vogue at some of the stations, are highly recommended against rheumatic pains.

Some of the affections for which the grape cure may be used as a reparative medicinal agent of great value are those arising from troubles in the functions of the organs of digestion, diseases of the liver and spleen, suppression of the hemorrhoidal discharge, menstrual derangement, etc. The cure is especially recommended by its partisans to persons of irregular digestion who have deluded themselves into the habit of taking purgatives. In simple opposition to this, the capital virtue of grapes has been demonstrated in the cure of inveterate diarrhœa — the *rationale* of which is that diarrhœa is rather a symptom of several diseases than a distinct morbid entity. The cure is also advised in catarrhs of the air passages, and to remedy the state of general exhaustion that keeps up all troubles of the respiratory apparatus. Alkaline and sweet grapes are used to relieve the vomiting of acid dyspepsia, or when it is desirable to liquefy the materials of the blood or bile; in hypertrophy of the liver or spleen, grapes containing large quantities of sulphates and phosphates are preferable. Treatment by the more astringent grapes along with general analeptic measures always gives good results when the object is to reconstruct the blood of anæmics, chlorotics, and convalescents. The grape diet is said to augment the urinary secretion and to diminish the formation of acids and salts of the urine, as in gravel and gout. Some German physicians, however, consider its indication as problematical in the uric acid diathesis. The uval cure may likewise be used as an adjunct or as a complementary cure in the treatment of impotency, since grapes taken in large quantities are decidedly aphrodisiacal.

But it is in certain neuroses, especially those in which there is great psychical depression, as hypochondria, melancholia, and hysteria, or in nervous states less cerebral than abdominal, that the virtues of the grape cure are brilliantly demonstrated. Relative to this subject, a confirmatory and most interesting case has occurred in my own practice. In February, 1884, I was consulted by a prominent business man of Washington, of middle age, who had suffered from obstinate insomnia and its train of evil consequences for eleven years, and during that time he had contracted the bromide habit. In addition to treatment by local physicians, he had successively been under the care of eminent neurologists in Philadelphia, New York, London, and Paris, with but indifferent results. His atavistic antecedents were not entirely satisfactory; but his venereal history was fairly good; he had stopped the use of tobacco, and his habits were temperate, though he was not a teetotaler. The patient complained of general languor and debility; of a clawing pain within the head; of inability to concentrate his thoughts, and of loss of will-power. He had, moreover, many of the symptoms peculiar to agoraphobia, the most prominent of which was the fear of an impulse to commit suicide. The patient stated that he had taken the bromides of potassium and sodium in almost incredible doses since 1873. From 1874 to 1876—a period of two years—he took daily one hundred and thirty-five grains, without missing a day. The quantity was gradually decreased in 1878 to eighty grains a day, and to fifty grains in 1883, during a visit to the "Healing Springs" of Virginia. He subsequently took ninety grains daily. The patient was cachectic in appearance; but there were no sensory, motor, or mental symptoms indicative of organic lesion. Examination with the differential calorimeter, however, revealed the existence of a considerable degree of cerebral hyperæmia. Under treatment my patient made but indifferent progress toward improvement, and having nearly exhausted my efforts to break up the bromide habit, I wrote to my friend, Dr. William A. Hammond, who informed me in reply that he had cured several cases of this habit by prescribing a solution of chloride of sodium, the dose of which is gradually increased, the bromide, at the same time, being correspondingly decreased until a few minims is reached, when the patient breaks off the habit on being told that he is taking nothing but table salt. This plan did well for several weeks, but during my summer absence in Europe, the patient accidentally learned from his druggist what he was taking, and immediately discontinued the prescription. On my return in autumn, I at once directed the patient to eat large quantities of grapes, the object of which was explained to him, and within a week I had the extreme satisfaction to see an important and salutary change in the symptoms. The languor and debility had left; the sleep was improved; there was not so much psychical depression, and the craving for the bromides was lessened. The habit is now entirely broken up; the patient sleeps fairly, is rid of melancholia, has regained his virility, to his great delight; and is in every respect improved and reconstructed.

As a matter of course, it is not pretended that positive deductions are to be made from the foregoing hasty out-

lines without the concurrent testimony of other observers and a more profound study of this subject. In view of the effects obtained by the grape cure in Germany, Switzerland, and Italy, it is regretable not to see it also common in America, notably in such regions as California, whose pure air, beautiful climate, and great abundance of excellent grapes, make it best adapted for the experiment of a uval station. With a view to farther comment on the subject, I take the liberty to solicit from those who may be prompted to try the grape cure a communication of the results of their observations. Since it is sufficiently demonstrated that the methodical and rational use of grapes suddenly breaks up all habits of nutrition, rapidly reconstructs the blood, and exercises a salutary action upon the nervous system, the grape-cure would apply to many persons in our large cities, who, in consequence of extreme heat and improperly cooked food, suffer from congested livers and intestinal catarrh, which they miscall malaria. Overworked clerks and newspaper men, who keep late hours and live on boarding-house fare, may derive from the vegetable milk of the luscious but inoffensive grape a rational means to re establish the physiological conditions of clear thought and correct expression; scrofulous subjects, lately under treatment at the Hot Springs, may complete the cure by means of the grape regimen, and ailing humanity of various grades may be benefited in many instances if they would replace the nasty drugs of the apothecary by the excellent fruit that graces the table and brings to pass so many delights.

IRVING C. ROSSE, M.D.

WASHINGTON, D. C.

"THE DUTY OF THE CONSULTING TO THE ATTENDING PHYSICIAN."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: After reading the article in THE MEDICAL RECORD of September 26, 1885, bearing the above heading, I thought I would relate a case that occurred in my own practice, if you will kindly allow it.

Soon after graduating I settled at U——, a country village, about two miles from Dr. H——, who had previously had nearly the entire practice at U——. My practice was good from the first, a fact more pleasant to me than to Dr. H——, doubtless.

About six months after my settlement I was called to attend I. T——, a boy of eight or nine years, the only son of an influential merchant of this town, and an acknowledged leader of his "circle." The case was one of bronchitis, quite severe, but with no unfavorable symptoms or complications.

About the fifth day I fancied I noticed a growing dissatisfaction, and I proposed a consultation, which was accepted with such alacrity as to confirm my fancies, They proposed Dr. H——, but I overruled them with the plea of not being acquainted, and they agreed to my sending for Dr. B——, whom I knew to be friendly. He came, saw the patient, agreed with me in diagnosis and treatment, gave a good prognosis, not only to me but to the friends.

I then believed everything to be satisfactory, until two days afterward, when, on returning home from a short trip of less than two hours, I was informed that Dr. H—— had been in to see my patient. On making my evening call the father excused Dr. H——'s call; said the boy grew worse; I was out of town; saw Dr. H—— drive by; called him in; looked at child; refused to say or do anything during my absence; had finally agreed to come and consult with me, if I wished, and as the father wished him to, I consented. He came; the patient was duly examined; we retired to a private room; I gave him all the facts in the case as I understood them; *he perfectly agreed with me in diagnosis, with me gave a good prognosis, and volunteered the statement that he did not see where my treatment could be bettered, unless it should be by the use of the atomizer, which he advised.* I accepted the suggestion and everything seemed amicable.

At my next visit I was startled with the information that as Dr. H—— had agreed to take the case, my services would no longer be required! That they presumed I had done as well as I knew how (!!), but they thought it better to have a doctor of longer experience.

I have since learned that Dr. H—— went back and told them that if the treatment was not changed the boy would die!! and with the anxiety that only parents can feel on contemplating the loss of an only child they made the change.

I shall always feel that I was cruelly treated by this doctor; but, as "Justice" says, "What remedy have we?"

Probably none. Cathell says, "Never expect justice from a rival."

JUSTICE, No. 2.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 27, 1885, to October 3, 1885.

MCPARLIN, T. A., Colonel and Surgeon. Directed to transfer his duties and the public funds for which he is accountable, as Assistant Medical Purveyor, to Captain Henry Johnson, Medical Storekeeper, who will, in addition to his present duties, temporarily perform the duties of Assistant Medical Purveyor, New York City. S. O. 223, A. G. O., September 29, 1885.

CALDWELL, D. G., Major and Surgeon. Ordered from Fort Laramie, Wyo., to Fort D. A. Russell, Wyo. S. O. 97, Department of the Platte, September 28, 1885.

BARTHOLF, J. H., Captain and Assistant Surgeon. Ordered from Fort Ringgold, Tex., to Fort McIntosh, Tex., for duty as Post Surgeon. S. O. 125, Department of Texas, September 28, 1885.

BRECHEMIN, LOUIS, Captain and Assistant Surgeon. Ordered from Fort D. A. Russell, Wyo., to Fort Laramie, Wyo. S. O. 97, Department of the Platte, September 28, 1885.

MACAULEY, C. N. B., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort A. Lincoln, Dak. Ter., and ordered for duty at Camp Poplar River, Mont. Ter. S. O. 105, Department of Dakota, September 21, 1885.

KNUDLER, WILLIAM L., First Lieutenant and Assistant Surgeon. When relieved from duty at Camp Poplar River, Mont. Ter., by Assistant Surgeon Macauley, to report to Commanding Officer, Fort Snelling, Minn., for duty. S. O. 105, Department of Dakota, September 21, 1885.

WALES, P. G., First Lieutenant and Assistant Surgeon. Relieved from temporary duty at Boisé Barracks, and ordered for duty at Fort Cœur d'Alene, Idaho. S. O. 160, Department of Colorado, September 21, 1885.

EWING, C. B., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Stanton, N. M., and ordered for duty at Fort Leavenworth, Kan. S. O. 147, Department of Missouri, September 25, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending October 3, 1885.

JONES, WILLIAM H., Surgeon. To Navy Yard, League Island, Pa., October 15th, as the relief of Medical Inspector M. Bradley.

BRADLEY, MICHAEL, Medical Inspector. Detached from Navy Yard, League Island, Pa., October 15th, and placed on waiting orders.

OWENS, THOMAS, Assistant Surgeon. To Naval Station, New London, Conn., as the relief of Surgeon William A. Corwin.

Corwin, William A., Surgeon. Detached from Naval Station, New London, Conn., and ordered to the U. S. S. Adams, October 31st.

Magruder, A. F., Surgeon. Ordered to the U. S. S. Yantic, without delay, as the relief of Surgeon H. L. Law.

Law, H. L., Surgeon. Detached from the U. S. S. Yantic, and wait orders.

Simon, W. J., Surgeon. Detached from the Naval Academy, October 1st, and wait orders.

Drennan, M. C., Surgeon. Detached from the Naval Academy, October 1st, and wait orders.

Cabell, Arthur G., Passed Assistant Surgeon. To the U. S. S. Adams, October 31st.

Medical Items.

Nickel-Plated Corpses.—An ingenious Frenchman has conceived the thoroughly Parisian idea of preserving bodies by covering them with a metal skin. Burying, he says, has been condemned by experience, cremation is bad, as it destroys all evidence of crime in case murder has been committed, and embalming is expensive. But galvanizing is safe and cheap. The poor can be zinc-plated, well-to-do individuals may acquire a copper coat, and the millionnaires can enjoy the luxury of silver or gold plate. M. Kergovaty, the inventor of this method, says he has already used it successfully eleven times in the case of human beings, and over a hundred times for animals.

International Congress of Otology.—The Fourth Otological Congress will be held at Brussels in September, 1888. At the Congress of Basle this year, it was announced that Baron Leon de Lenval, of Nice, had offered a prize of three thousand francs to the author of "the best application of microphonic principles in the construction of an easily portable apparatus for improving the hearing." The instruments, complete and ready for use, should be sent to one of the members of the Committee prior to December 31, 1887. In the examination of instruments regard will be had to the excellence of mechanical construction, to the proper observance of the laws of physics, but chiefly to the amelioration of hearing produced by the instrument. The prize will be awarded during the sessions of the Fourth Congress. If no instrument shall be deemed worthy of the prize, the Committee may extend the period of competition up to the date of the opening of the Congress. The members of the jury of award are Dr. E. Hagenbach-Bischoff, President, Missionsstrasse, 20, Basle; Dr. Benni, 16 Bracka, Warsaw; Dr. Burckhardt-Merian, 42 Albanvorstadt, Basle; Dr. Gellé, 20 Avenue de la l'Opéra, Paris; Dr. Adam Politzer, 1 Gonzagagasse, 19, Vienna.

Artificial Conception.—Not long ago a candidate presented to the Faculté de Médecine, of Paris, a thesis upon artificial conception, but after a long and somewhat heated discussion, it was determined to reject the thesis, and to destroy all the printed copies. The grounds given for this decision was, that if the thesis were approved, it might give an opportunity to certain unscrupulous physicians to carry on an unclean business, dangerous to the family and to the State. It is not often that Paris gives evidence of the possession of many scruples in such matters.

Operations in Mission Hospital in Cashmere.—Cashmere contains, in addition to its numerous shawl manufactories and papier maché and silver industries, an admirably conducted hospital attached to the mission of the Church Missionary Society, the present medical officers of which are Messrs. Arthur Neve, F.R.C.S.E., and H. D. McCulloch, M.B., C.M. In the report of last year's work, just issued, they say: "Although the number of out-patients is not larger than last year, the wards have been much fuller, and the operations more numerous and more severe. There have been 5,366 out-patients who paid 13,700 visits to the hospital. About 1,000 other patients were treated when itinerating in the valley or on a journey to Ladak; 1,054 operations were performed, of which 339 were major. Only 6 deaths occurred. During 1883, with 800 operations, we had only 1 death. Last year growing experience and the increasing confidence of patients has allowed bolder measures. No cases in which operative relief seemed possible were turned away. Many patients have come over 200 miles for treatment. One man totally blind was brought 250 miles and over snow passes. Both his eyes were successfully operated on. He walked back seeing." In the detailed list of operations there are mentioned 32 successful cases of nerve-stretching for leprosy, 3 excisions of the hip, 344 minor eye operations, and 3 lithotomies. The Maharajah has shown his appreciation of the work done for his subjects by giving substantial help in repairing and adding to the Mission Hospital.

Personal Medical Nomenclature.—A correspondent writes: "From your excellent editorial in last week's Record, I have more fully realized what has always seemed a great blunder in medical literature. I refer to the 'Personal Medical Nomenclature.' I trust you will keep up the hammering at this subject." By another correspondent we are reminded that we failed to mention Menière's disease, or labyrinthine vertigo. Sciatica has gone, in times past fortunately, by the name of Cotugno's disease. French writers speak of Parrot's disease, or syphilitic pseudo-paralysis of children. Recently nosology has been in labor again, and we have Gillis de la Tourette's disease, a peculiar form of chorea, described sometimes as latah, and myriachit.

Western Medical Colleges and Instruction in Mental Disease.—Dr. G. F. Harvey, of Parsons, Kans., criticizes a statement of Dr. John W. Wood, of the Trenton Insane Asylum (Medical Record, June 20, 1885, p. 694), to the effect that "general paresis" is a disease not mentioned in lectures at medical colleges. Dr. Harvey sends us excellent notes of a lecture on this disease by Dr. Walter Hays, delivered at Rush Medical College, January 19, 1876.

Some Lay Advice to Doctors.—Avoid the society of your patients. Physicians should have no familiars; to be thoroughly respected they must stand aloof from the gaze of society. A prophet has no power in his own country, neither has a physician in his own circle. Without skill it is impossible to become a flourishing physician, but without good manners all the skill of the most eminent physicians will not avail you in a large capital. A good address is everything to a doctor. Never refuse a fee from any person who is able to give one, in order that you may never have occasion to take one from a man who is too poor to well afford one. It matters not how mercenary you may be accounted by the rich, so long as you are merciful to the poor. If you cannot get fees without depriving them of bread, it were better you had never been a doctor.—*Brooklyn Eagle.*

Chloroform and Tapeworms.—Dr. A. T. Boder, of Grand Rapids, Mich., writes that he has successfully treated a patient suffering from tapeworm by administering chloroform, ol. fil. mas, āā ℥ ss.; olei ricini, ℥ jss.

Performing the Operation for Strabismus on a Hypnotized Patient.—Dr. S. L. McCurdy, of Dennison, O., writes that he has recently performed the operation for strabismus successfully on a mesmerized patient, a young man of eighteen. The patient showed no signs of pain, and was brought out from his mesmeric state at once, when he showed none of the disagreeable after-effects that result from the use of ether.

OBSCURE CASES OF WEAK HEART.[1]

BY R. VAN SANTVOORD, M.D.,

NEW YORK.

WEAKNESS of the cardiac muscle, occurring independently of valvular lesion, is recognized as an important pathological factor in a large number of morbid conditions. It is one of the chief sources of danger in most acute febrile diseases, and it remains as a residual disorder after many of them, particularly after typhoid fever. It occurs as a result of long-standing anæmia, and of various toxic conditions, among which alcoholism is prominent. Failing cardiac compensation is frequently the cause of death in chronic renal disease. The right ventricle is often affected in pulmonary diseases involving obstruction to the lesser circulation. Degeneration may result from inflammation of the cardiac muscle occurring in the course of various general diseases, or as the secondary result of lesions of the coronary vessels. The heart may give out as the result of repeated strain. The heart-muscle itself after death may be in a state of granular, fatty, fibroid, or waxy degeneration, as the result of one or other of these conditions; or its histological structure may be apparently normal, although the ante-mortem history and the dilated cavities of the organ point to cardiac failure as the cause of death.

It is not my intention to attempt the impossible task of covering this wide field in a single paper. Many of these cardiac conditions are among the best recognized features of the general morbid states with which they are associated. In others, again, the connection between symptoms and the underlying cardiac lesion is obscure and easily overlooked, from the absence of striking physical signs of cardiac disease. It is my purpose to confine my attention to this latter class of cases, considered from a clinical point of view. As a positive diagnosis can frequently be made *only* after careful study of the individual case and balancing of the various symptoms and physical signs observed, it has seemed to me that my not very easily circumscribed subject could be most suggestively presented by the relation in brief of a few cases which have come under my personal observation, with comments upon the special points of interest which they present.

I.—My first case was that of a fresh-looking, slightly corpulent man, aged forty-two, who was apparently the picture of robust health. He was a dry-goods salesman by occupation, and beyond occasional drinking with a customer, and too rapid eating, his habits were in every way good. His indulgence in alcohol was never excessive. He complained of sleeplessness. It was difficult to rouse him in the morning after a full night's rest. He would frequently fall asleep at any time during the day when not actively occupied. He suffered from frequent headache, which glasses prescribed by an oculist to correct hypermetropia relieved but little. He was forgetful and not able to attend to his business as well as formerly. On being questioned he recalled that he was somewhat short of breath on going up stairs, but had not been much annoyed by this symptom. He suffered also at times from slight disturbances of digestion. His urine was normal. The only evidence of organic derangement discovered was that the heart-sounds, especially the first, were rather weak, and reduplication of the second sound was audible at the base. The pulse was 75. The patient's symptoms dated from a severe attack of pneumonia, two years previous to any attendance, his health having been good prior to that time. A diagnosis of weak heart following pneumonia was made, and ten minims each of the tincture of digitalis and tincture of nux vomica t. i. d. were prescribed, the latter being given to correct existing derangement of digestion. After two weeks of this treatment the heart-sounds were louder, but the patient's condition was not materially improved. A single sphygmographic tracing showed no obvious abnormality and was not preserved. Five grains of the citrate of caffeine after meals was now substituted for the digitalis, and one-thirtieth grain of strychnine for the nux vomica. Owing to a misunderstanding the caffeine was at first taken before meals and caused much gastric irritation. When the mistake was corrected the good effect of the drug at once became manifest. His heart-sounds became louder and his disagreeable symptoms disappeared. At first, if he forgot a powder, the sleepiness would return. After two or three weeks the dose was reduced to three grains, and was continued for a week or two longer. Ten weeks after commencing the caffeine treatment he had retained his gain, but had to take an occasional three-grain powder after breakfast, to avoid sleepiness. His weight had been slightly reduced, and a tendency to flatulence was controlled by abstinence from sugar and potatoes. When last seen, twenty-three weeks after the commencement of treatment, he was in a comfortable condition, though still slightly short of breath, and flatulent from dietary indiscretions. His sleepy attacks had recurred two or three times under strain, but had quickly yielded to caffeine, taken without consulting me. The only abnormality noticed about the heart was the persistence of the reduplication of the second sound, which was heard at the end of inspiration and beginning of expiration over the left of third intercostal space near the sternum.

II.—My second case was that of a stock-broker, aged thirty-eight. Several relatives had been gouty, and one had been asthmatic. He had had several slight attacks of gout, and had been much worried about business losses and had been drinking freely, chiefly spirits, for three or four years. He had been short of breath for years on going up-stairs. A former medical attendant had found albumen in his urine. His ankles would become puffy from time to time, especially after drinking brandy. He had been rejected by a life insurance examiner some months before on account of the rapidity of his pulse. He had for some time vomited every morning on rising, the matter vomited being usually mucus, but twice it contained blood. His custom had been to take from twelve to fourteen drinks of whiskey a day, and to eat only one meal, that being in the afternoon. I was called to see him on account of attacks of dyspnœa and wheezing, which had been coming on every night for some time.

I found him to be a pale, worried-looking man, gray, and appearing much older than he was. At my first examination, the dyspnœa was slight. The lungs were normal. The first sound of the heart was weak, the second hard, metallic, and not quite clear. His tongue was coated, and he complained of flying pains in his muscles.

[1] Read before the New York Academy of Medicine, October, 1885.

The urine contained a small amount of albumen, had a specific gravity of 1.024, and one fatty cast was seen after considerable searching. Six days later, after appropriate treatment of the stomach, the stopping of alcohol, administration of food, and the use of morphia and Hoffman's anodyne at night, great improvement followed. He passed something over a quart of urine, of a specific gravity of 1.014, in twenty-four hours, containing no albumen. As soon, however, as he began to go about again, dyspnœa and inability to lie down without distress recurred. The first sound and the apex-beat of the heart were feeble, the pulse 102. His appetite began to fail again. He had occasional shooting pains from the apex of the heart to the scapula.

Ten minims of the tincture of digitalis t.i.d., combined with a bitter tonic, were given—as were also other remedies rendered necessary by the condition of the stomach and bowels. In two days he was able to sleep flat on his back through the night. His pulse dropped from 102 to 84. Its tension, which, as shown by the sphygmograph, was very low before the digitalis was given (Fig. 1),

Fig. 1.

Fig. 2.

increased considerably (Fig. 2), but did not become normal. He succeeded in abstaining from alcohol and, when examined six months later, had gained markedly in flesh, no longer suffered from dyspnœa, and, in spite of constant business worry, was in a very comfortable general condition. The first sound was still short and valvular, the second metallic and sharp, the arterial tension low, the pulse 82. The urine showed a faint trace of albumen, by the mercuric iodide test, and a considerable number of hyaline casts.

In this case the patient's abuse of alcohol and underfeeding had undoubtedly caused a pretty general degeneration or state of malnutrition of all his organs. Reform of these habits was the *sine qua non* of his recovery. His rapid and persistent improvement after a course of digitalis, with corresponding improvement in his cardiac action, is proof, however, that his heart was the organ predominantly affected. The normal quantity of his urine, the small amount and inconstancy of the albumen which it contained, the absence of elements in the deposit pointing to active kidney trouble, the persistent low tension of his pulse, and his rapid improvement, go to prove that the albuminuria was probably not associated with grave organic changes in the kidneys. The lesion in this case is conjectural. From the association with abuse of alcohol it may be assumed that the heart was fatty, but the very rapid response to digitalis seemed to indicate that a less grave state of malnutrition probably predominated. There was also a persistent irritability of the heart, due apparently to his mental worry, and analogous to the irritability noted by Da Costa[1] as the result of the physical and moral hardships of campaign life, the abuse of tobacco, etc. It is, I believe, customary to regard these cases of irritable heart as of little gravity. Da Costa, however, has recorded a case of dilatation and hypertrophy following irritable heart due to worry and uterine disease, and also a case of dilatation and hypertrophy, with mitral regurgitation, following irritability from the abuse of tobacco and worry. Similar cases have been recorded by other authorities.

III.—My third case is that of a gentleman, aged fifty-four, who had always been much addicted to outdoor sports. His health had been good until his present trouble began, except that he had always suffered from constipation. Some months before consulting me, he began to suffer from lassitude, drowsiness, indisposition to exert himself physically or mentally, and a constant distressing headache felt chiefly at the vertex. He had been treated for hæmorrhoids by ligature a few months before. His eyes had been recently examined by Dr. Knapp, who told him that they presented the lesions usually associated with myopia, but nothing to explain his general symptoms. For a long time he had been obliged to get up at night to urinate. The immediate occasion of his consulting me was an unusually severe attack of pain in the vertex and back of the head, in part shooting in character, but not following any definite nerve distribution.

The patient was a thin, sallow, anxious-looking man. His tongue was slightly coated. His appetite was good. The apex of his heart was in the sixth interspace in the nipple line, and a very faint systolic murmur was heard at that point. The cardiac sounds, especially the second, were weak. The lungs were normal. He passed about ninety-six ounces of urine in twenty-four hours, the specific gravity of the specimen measured being 1.010½; it contained no albumen. A mixture containing bicarbonate of soda and gentian given for two days, with the idea that the head symptoms might be reflex from the stomach, produced no effect. Of various remedies used for the bowels, faradization only had any effect. Ten minims of the tincture of digitalis and twenty of the tincture of the chloride of iron t.i.d. were now prescribed. During the twelve days that the patient remained under observation, the heart-sounds increased markedly in force, the pulse became stronger, and his general condition improved remarkably. The urine fluctuated in specific gravity between 1.010½ and 1.019½ in four examinations. Its frequency of passage, and presumably its quantity, did not diminish. No albumen or sugar was found. On one occasion a few hyaline casts with adherent renal epithelial cells were seen; spermatozoa were observed in three of the four examinations, and a few pus-globules were always present. It was then ascertained that the patient had been treated for urethral stricture, originating in the usual way, thirty years before. A No. 14 English sound was the largest that could be passed through a constriction two and a half inches back of the meatus. Seminal emissions had occurred, and ejaculation had been painful of late years. From the enlarged heart, and the large amount of urine passed, it was concluded that the patient was suffering from contracted kidneys with secondary cardiac failure, although the specific gravity of the urine was usually normal, and no albumen was at any time found. The patient spent the winter in a southern climate, and remained in a fair state of health, taking no treatment during most of the time, but avoiding exposure and muscular strain. A year after his first course of treatment he presented himself, stating that he was a little short of breath on going up-stairs, that he had no pain but only a sensation of something not quite right in his head, which he could not define, and occasional shooting pains in his arms and legs. His condition was somewhat aggravated by recent unusual exertion. The apex of the heart was in its former situation; the sounds, especially the second, were weak; a distinct reduplication of the first sound was heard to the left of the sternum at the level of the fourth rib, but not at the apex, where the muscular element seemed to cover it. There was no murmur. The sphygmographic tracing (Fig. 3) was of very large amplitude, but the tidal wave was more marked, the aortic notch much higher in the tracing, and the dicrotic wave far less developed than in the second case narrated. The pulse was 75. Digitalis in ten-minim doses t.i.d., first alone and after five days with half a drachm of fluid extract of ergot, continued for ten days, caused a diminution in the amplitude of the pulse, a lessening of the dicrotic wave, and a lowering of the pulse to 64. The sphygmogram, after this treatment, differed from the most common healthy type only in being a little below the average tension. The shooting pains became somewhat less under treatment, but there was no great

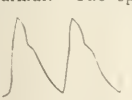

Fig. 3.

[1] Toner Lectures on Heart Strain, 1874.

change in his, at this time, not very markedly disagreeable symptoms, owing probably to unusual exertion and the temporary discomfort of an acute coryza. The urine, examined once, had a specific gravity of 1.015, contained no albumen, and the microscope showed only a few pus- and red blood-globules. He passed seventy ounces in the twenty-four hours.

The facts that the patient had held his own for a year, that the specific gravity of the urine was normal (considering the amount passed), and that the sphygmographic tracing taken on four different occasions showed low arterial tension, even after the heart had been strengthened by appropriate treatment, led me to conclude that the polyuria was due to some cause other than contracted kidney, it being possibly a reflex result of the urethral lesion such as was observed by Masson[1] in four per cent. of the cases of stricture studied by him. Masson found polyuria, especially in patients with stricture of long standing. After treatment of the strictures the polyuria disappeared or lessened. My patient did not remain under observation long enough at any one time to enable me to test this question by treating the stricture.

The cardiac failure, therefore, seemed to be an independent matter. The age of the patient (fifty-four years) points to an early stage of one of the chronic degenerative processes. His addiction to athletic sports suggests the weak, dilated heart without recognizable histological change, such as has been noticed by Münziner[2] among the Tübingen vine-dressers, who are accustomed to carry heavy loads on their backs in a hilly country, or the cardiac dilatation observed after Alpine climbing;[3] but any absolute conclusion on this point seems impossible.

IV.—My fourth and last case can hardly be classed as one of obscure cardiac weakness, as the symptoms were very striking. I introduce it on account of certain features of especial interest which it presents. The patient was a boy aged fourteen, who had a severe attack of measles last May, he having been previously in good health. After his convalescence, he suffered from dyspnœa and lancinating pain in the cardiac region on running. He was admitted into the Randall's Island Hospital on July 30th. The boy was thin and pale. Cardiac pulsation was marked over the apex, in the epigastrium, and in the second left intercostal space. Both ventricular areas were enlarged. The heart-sounds were loud. Distinct reduplication of the second sound was audible in the third left interspace near the sternum. A loud blowing systolic murmur was heard over arteries at the base of the neck, and was transmitted into the brachials and femorals. Under iron, strychnia, and rest the boy's general condition improved; the dilatation of the heart had diminished; the arterial murmur had disappeared, the venous hum had lessened, and the reduplication of the second sound still persisted at my last examination.

Although endocarditis and pericarditis occur as occasional complications of measles, the absence of cardiac murmurs and the rapid improvement, both local and general, point to the condition as one of cardiac dilatation, with perhaps some fatty degeneration such as has long been recognized as occurring in long-standing anæmia, especially in chlorosis; the dilatation sometimes proceeding so far as to cause relative incompetence of the mitral valve and consequent regurgitation.

On reviewing this little group of cases, attention is arrested by the fact that reduplication of one or other of the cardiac sounds was present in three of them. The etiology of this phenomenon has been much discussed. The simplest explanation is, that the reduplication of the first sound is due to asynchronism in the contraction of the ventricles; that of the second to asynchronism in the closing of the outer and pulmonary semilunar valves. Bramwell is of the opinion that this is the explanation in at least the great majority of cases. Other high authorities have invented a number of ingenious hypotheses to meet certain cases in which there are apparent objections to this simple theory. These alternative explanations, being apparently incapable of *experimental* proof or disproof, must be accepted or rejected on purely theoretical grounds. None that I have met with seem to my mind mechanically possible. Dr. Bramwell[1] states that he has seen, felt, and heard asynchronous action of the ventricles. "Each side" of the heart, he says, "has more or less independently its own nerve-supply, its own peristaltic action; and notwithstanding that both sides are set to the same time, and that there is a complex interlacement of fibres, yet it is quite possible, nay, it is an experimental fact, that one side may begin or end contraction before the other." It therefore seems to me that Bramwell's opinion is correct. Both forms of reduplication are said to occur physiologically as temporary phenomena, owing to the effect of the respiratory movements on the circulation, especially when those movements are forcible. Reduplication of the first sound occurs at the end of ex- and beginning of in-spiration. Reduplication of the second sound, at the opposite point of the circle, *i.e.*, at the end of in- and beginning of expiration. The physiological stimulus to contraction of the ventricles is recognized to be the distention of their cavities with blood. One ventricle may therefore contract before the other, according to Bramwell, when either the blood-pressure in one is greater than in the other, or when, the blood-pressure being the same, one ventricle is more irritable than the other, owing either to a relatively greater derangement of its nerve-apparatus, or to structural changes in its muscular wall. The lack of synchronism caused by the influence of respiration is due probably to the fact, that at the end of expiration more blood is actually delivered to one ventricle than to the other. Usually during tranquil respiration the lack of synchronism, though probably present, is not sufficient to be appreciable. In the case above cited of the patient with a dilated left ventricle resulting possibly from heart strain, the reduplication of the first sound was heard during tranquil respiration on two different occasions, and was therefore probably not of the physiological type.[2] There existed manifest dilatation of the left, but not of the right, ventricle. Now the amount of blood delivered to each ventricle at a given cardiac contraction is about the same, the variations caused by respiration being probably unimportant so long as that act is tranquil. The undilated right ventricle would therefore be more distended than its dilated fellow by a given quantity of blood, and would consequently contract sooner, thus giving rise to a reduplication of the first sound. The contraction of a weak ventricle is, however, less sustained than that of a normal one, so that, in spite of a later start, the left ventricular contraction might terminate synchronously with the right. It must be borne clearly in mind that it is here a question of intra-ventricular pressure during ventricular *diastole*. In other pathological cases, as above stated, it may be a question of a disturbed balance of the relative irritability of the ventricles. Marked degeneration or nervous derangement may exist, but as long as both ventricles are equally affected no reduplication would be produced. Apart, however, from purely theoretical speculations, which some unknown or unconsidered factor may entirely vitiate, persistent reduplication of the first sound has been found clinically associated with functional disorders of the heart, and with grave organic changes of the cardiac muscle with or without valvular disease. It is at least within the limits of our present knowledge of the subject to say that its presence in a given case is presumptive evidence of some cardiac lesion, the character and gravity of which must be determined by the other factors of the case.

[3] Overstrain of Heart and Aorta (with discussion). Allbutt: Brit. Med. Jour., March 15, 1873.

[1] Bramwell: Diseases of the Heart, 1st ed., p. 160 (note).
[2] My recollection is that it was also continuous, *i.e.*, not depending on respiratory influences, but my notes of the case are not specific on this point. Such reduplication would of course be entirely unphysiological.

In the case of the second sound, reduplication may be due either to derangement of the nerve-apparatus, or lesions of the muscular fibres of the heart, which cause the contraction of one ventricle to be shorter than that of the other, or to disturbances in the relative amount of resistance to be overcome by the respective ventricles. The semilunar valves must close the moment that the arterial tension is greater than the pressure from behind. Increased resistance, however, is met by increased vigor of contraction on the part of the ventricle upon which the strain comes. This increased vigor of contraction involves a lengthening of the ventricular systole. It is this increase which, according to some authorities, gives rise to the reduplication of the second sound, which is observed in a large percentage of cases of mitral stenosis, the right ventricle in this case being called upon to make so prolonged an effort in the performance of its work that the closure of the pulmonary valve is later than that of the aortic. There are objections to this theory advanced by high authorities, such as Guttmann and Sansom. My limited time will not permit me to consider these objections in this place. I must content myself with remarking that to me the objections offered seem to admit of plausible answers, but the alternative explanations seem improbable. The reduplicated second sound in the case of dilated heart in an anæmic boy, above cited, was probably one in which the high tension of the greater circulation, shown by the sphygmograph, together with a factor to be mentioned later, caused a prolongation of the left ventricular systole, thus causing a reduplication, in which the aortic element was the last (Fig. 4).[1]

Fig. 4.

When the peripheral resistance in both circulations is normal, reduplication of the second sound may be supposed to occur from unequal length of contraction in the ventricles, due to a preponderance of muscular degeneration or nervous derangement in one as compared to the other. Possibly the reduplicated second sound in the case of weak heart following pneumonia, cited above, was due to enduring predominant weakness of the right heart, upon which the greater strain comes in that disease. Its shorter contraction would, in that case, make the pulmonic the first element of the double sound.

It is theoretically conceivable that in mitral stenosis, for example, a time would arrive at which the ventricle upon which the extra strain was thrown would lose its power of prolonged contraction owing to advancing degeneration, and that a reduplication which was present earlier in the case would disappear. This seems to me to be the answer to Guttmann's most formidable objection to the above-accepted explanation of reduplication of the second sound in these cases, his objection being that the reduplication is often absent in the most marked examples of the lesion. Now, it is in precisely those cases in which we would expect secondary failure of the right ventricle.

Again, it is conceivable that an obstruction to either circulation which would not produce a sensible prolongation of the systole of the affected ventricle in health, might have that effect when *both* ventricles were somewhat weakened. In such a case the contraction of the unobstructed ventricle would be shorter than normal. The systole of the affected side would be longer than that of the other, but still not as long as the contraction of a healthy organ would be in parallel circumstances, *i.e.*, when acting against an obstruction which bore the same proportion to its strength. These considerations may explain why, in the case of the anæmic boy, the increased arterial resistance was able to cause a perceptible reduplication of the second sound. In the case of weak heart resulting from the abuse of alcohol and general malnutrition, the cause being a general one, both ventricles may be supposed to have been equally affected. The absence of a reduplication of the second sound in this case may have depended on the low arterial tension.

Apart, however, from all theory, as a matter of clinical observation, reduplicated second sound is so frequently associated with obstructions to the greater or lesser circulations, with lesions of the cardiac muscle, or with a combination of both, that its occurrence, as in the case of reduplication of the first sound, should lead to a careful study of the case, with a view to determining the presence or absence of important cardiac disease. In my case of weak heart following pneumonia, the reduplication of the second sound was heard, when last listened to, only at the end of inspiration and beginning of expiration, *i.e.*, it was of the normal type. The patient's condition at the time was comfortable, and an observer knowing nothing of his former history might readily have concluded that the sign was without significance. The facts that he was still slightly short of breath on exertion, that his morbid symptoms had returned under strain on two or three occasions, and that the reduplication was heard during quiet respiration, go to prove that such a conclusion would be incorrect.

Weakness of the first sound of the heart, accepted generally as an indication of cardiac debility, was present in three out of the four cases. In the case of dilated heart in an anæmic boy, however, the first sound was sharp and ringing. Reference to the sphygmographic tracing (Fig. 4) shows that the condition of high arterial tension common in anæmia was present. Recalling the fact that during ventricular systole the cavities of the ventricle and aorta are continuous, and that vascular tension is produced by the *resistance* to the flow of blood, it is at once evident why weak cardiac contraction may yet be accompanied by a loud cardiac sound.

A striking feature, however, of Cases II. and III. was that even when after treatment the ventricles were acting fairly well, as indicated by the improvement in the symptoms of the patients, yet the first sound of the heart, though stronger than before, was still noticeably weak, and there was no extra-cardiac factor, such as thickness of the chest-walls or emphysema of the lungs, to explain that weakness. On referring to the sphygmograms (Figs. 2 and 3), the explanation is obvious.

In both these cases persistent low mean arterial pressure was present, a condition due obviously to persistent dilatation of the small arteries. At the moment of the ventricular systole, therefore, the blood met with very little resistance on entering the aorta. Consequently the intracardiac pressure and the reverberation of the valves thereon depending, remained below normal in spite of the more vigorous contraction of the ventricles. It is obvious, therefore, that in interpreting the meaning of a short, weak valvular first sound, the peripheral resistance to the circulation is quite as important a factor as the strength of the ventricular contractions.[1]

Another striking point of contrast between these cases was, that in the weak irritable heart following the abuse of alcohol the second sound was loud and metallic, while that in the case of dilated heart following muscular strain was markedly weak.

Referring again to the sphygmographic tracings, in the former it will be observed that the pulse wave is pointed and the tension falls off without interruption (Figs. 1 and 2), showing a quick, sudden ventricular contraction. The semilunar valves close, of course, at the moment that the pressure in the aorta becomes greater than that in the ventricle. In this case, from the form of the ventricular contraction, it seems obvious that the valves were

[1] In the interpretation of this tracing, it is to be remembered that the patient was young (fourteen years), and his arteries therefore elastic. The rapid falling off of the primary wave is the result of this factor. The high tension of the vessel is shown by the gradual descent of the pulse wave from the "tidal wave" onward.

[1] I do not know that this condition of permanent relaxation of the peripheral arteries has been or can be regarded as a distinct pathological entity. I have somewhere seen the statement, though I have not been able to recall the reference, that persons in whom this condition exists show very little power of resistance when attacked by serious acute disease.

closed by the full force of the retraction of the aorta, unresisted by any pressure from behind. In the second case, however (Fig. 3), the presence of the tidal wave and the higher position of the aortic notch in the tracing show that the ventricle contracted more gradually, and that the aortic valves were probably closed in the face of a still advancing column of blood, their vibration being consequently weaker than in the former case. In interpreting, therefore, the meaning of a strong or a weak second sound, it is necessary to consider not only arterial tension, but also the form of the ventricular contraction. It must be remembered, however, as Cohnheim insists, that many degenerated hearts functionate in an absolutely normal manner, so long as the demands upon them are within their ability to respond. In such cases diagnosis can be made only on such evidence of cardiac distress *under strain* as the history of the patients may furnish. I am convinced, however, that closer observation and analysis of the less striking evidences of deranged cardiac action would greatly lessen the number of cases of grave cardiac lesion which remain totally unsuspected during life, with which most physicians, who have opportunities for comparing their ante-mortem diagnoses with the revelations of the autopsy room, are probably only too familiar.

In conclusion I desire to say a few words about the contrasted action of the two cardiac tonics, digitalis and caffeine, suggested by the above cases. According to the careful experiments of Riegel,[1] caffeine, like digitalis, slows the action of the heart and increases the amplitude and tension of the pulse, both in health and disease. In cardiac failure, like digitalis, it renders the heart contractions more regular, increases the amount of urine, and decreases the amount of albumen and the specific gravity. The slowing of the normal pulse by caffeine is spoken of as moderate. It differs from digitalis in its more rapid action and in the absence of cumulative effect. In some cases of failing heart caffeine was efficient after digitalis was found useless. In the above-cited case of weak heart following pneumonia, digitalis, given in doses which are ordinarily efficient, produced little or no good effect, but improvement followed at once on using caffeine. In Cases II. and III. marked improvement followed the use of digitalis. In the first case the sphygmograph showed no abnormality of the pulse tension. In the other two a permanent relaxation of the peripheral arteries was shown to exist. It is an old theoretical objection to digitalis that in a patient with degenerated heart the contraction of the peripheral arteries which it causes may more than offset its tonic effect on the cardiac muscle, the heart being unable to respond to the stimulus by virtue of its degeneration. Bramwell cautions against its use in fibroid heart on this ground. Trousseau[2] states that certain cases of dilated heart are made worse by it. It is suggestive that in the two cases cited above, that were benefited by digitalis, the tension of the pulse was only slightly increased by its administration. There seemed to exist a permanent dilatation of the peripheral arteries, upon which digitalis produced little or no effect. In the case which was not benefited, as far as could be judged from a single tracing, arterial tension was normal. It seems plausible to suppose that the contrasted effects of the two remedies may lie in the slighter influence of caffeine on the vaso-motor apparatus. This suggested explanation requires, of course, further study.

The fact remains nevertheless, that caffeine sometimes is efficient when digitalis fails. In Riegel's experience the contrary was the case in only a single instance, and in that the caffeine could not be tolerated on account of the gastric irritability and cerebral excitement which it caused. These symptoms are, however, not often produced. The greater safety and more rapid action of the drug point to it as preferable to digitalis as a cardiac tonic in heart failure occurring in acute diseases or primary degenerative processes of the cardiac muscle. The soluble and stable combinations of the drug with salicylate or benzoate of soda are to be preferred to the insoluble and unstable so-called citrate which has been long in use. It should be given in divided doses, at first small, but pushed as high as two grammes daily, according to Dujardin-Beaumetz,[1] if smaller doses are not efficient.

In my narration of cases and my comments I have probably said little that is not already known to many of my hearers. I believe, however, that cases of the kind under discussion do not, in practice, receive the recognition which their frequency and importance deserve. It has *not* been my aim to treat my subject exhaustively, but to call attention to the fact that conclusions of the greatest practical importance can be arrived at, not by rule-of-thumb diagnosis, but by careful study of the symptoms and less striking physical signs present in *individual* obscure cases of weak heart.

NOTE ON THE THERAPEUTICS OF HAY-FEVER (SO-CALLED).

By BEVERLEY ROBINSON, M.D.,

NEW YORK.

The proper season for a contribution on this subject, be it never so brief, has in the opinion of many come to an end. To my mind this is not true. Of course, if I were willing to admit that "cocaine" is the panacea for this troublesome disease, as the daily press and a few of our prominent medical brethren believe, I should be willing to await the advent of another summer, or autumn, before I felt called upon to "mark time" with other observers.

But this is not my conviction. Neither cocaine nor the relative severe means of the electro-cautery appears to me essential in redeeming our hay fever victims from actual or future attacks. Within a period of a few weeks, I have been called upon to treat three sufferers from hay fever. In the first case, that of a young lady of a neighboring city, the attack of hay fever was *evidently* occasioned by a sudden and considerable fall of temperature, and had nothing to do with the *pernicious pollen*, or a *derangement of the nerve-centres*. To this patient, and in anticipation of an attack, her physician had given a four per cent. solution of hydrochlorate of cocaine. When the periodical attack of hay fever took severe hold of her, when sneezing was repeated and violent; when the conjunctivæ were red and swollen, when rest at night was impossible, on account of the severity of dyspnœa due to asthma, cocaine was repeatedly and faithfully tried. At first it was dropped into the nasal passages; later it was used in the form of a fine spray. During two days partial relief was afforded, so far as the symptoms of *sneezing* and *nasal obstruction* were concerned. Subsequently the sneezing was stopped for a short time, but the obstruction was more marked, and the asthma was not at all relieved. Thereupon I made a very thorough and complete application of carbolic acid, one part, glycerine, three parts, to the nasal mucous membrane and gave very great temporary relief, which, indeed, lasted almost twenty-four hours. The following day I repeated the local application and had no further occasion to make use of it. The sneezing, nasal obstruction, and bronchitic asthma had nearly disappeared, and a few days later my patient was entirely well.

Since the time I treated the case just reported I have had two others under my care, marked, however, by more or less continued nasal occlusion, but having already passed beyond the period of paroxysmal sneezing. In neither of these cases was there any asthma, or nota-

[1] Bull. gén. de Thérap., 1884, cvii., 97-111.

ble ocular suffusion. Cocaine had been used freely and often. It had relieved during the first few days in a temporary manner; subsequently it had increased nasal obstruction. What I have noticed in this place in regard to hay fever, I have already seen several times, where cocaine had been used frequently in the nasal passages, for other diseases, viz.; that it causes secondary occlusion of the nasal passages, due, as I believe, to a paralytic condition of the turbinated structures caused by its action. In my two late cases of hay fever I obtained notable relief by two or more applications of carbolic acid, one part, glycerine, two parts, but not to the remarkable degree that I did in my first case. I explained this by the fact that these were very different as regards the pathological conditions present. In one case there was considerable thickening of the septum, and a small bony exostosis situated posteriorly in the nasal passages; in the second case there was septal deviation and marked posterior turbinated hypertrophies with bands of membranous tissue going from the right inferior turbinated body to the posterior border of the septum. These cases were much benefited for the while by alterative ointments and applications of compound tincture of iodine. Subsequently, they may both require the use of the cautery, or that of the saw and rougene forceps. These patients' general condition was unimpaired; at all events there was no satisfactory evidence of a hyper-sensitive state of the "cervico-occipital sympathetic."

I spoke two years ago, at a meeting of the Laryngological Association, in the city of New York, of a case of hay fever much benefited by applications of carbolic acid. I again wish to direct attention to its use at the present time. I presume it does good, when it is of any use, mainly by modifying or destroying "sensitive areas of mucous membrane." I do not yet know whether it will accomplish its purpose as well as the galvano-cautery, but I have, at least, some ground for this belief.

Certainly, the cautery is not applicable to *all organic diseases* of the nasal passages, and I am, also, *now* of the belief that in the majority of cases, hay fever is quite *independent* of any morbid condition of the *nerve-centres*. It seems to me apropos to make this statement, in view of Dr. J. H. Mackenzie's elaborate, but somewhat speculative articles, all pointing to an omnipresent "rhinitis sympathetica," or of Dr. Morell Mackenzie's remarkable apology for the nearly discredited *pollen theory* of hay-fever among scientific observers.

Eating Glass for a Living.—Dr. C. C. Burke, of Texarkana, Tex., sends us the following curious account, for the authenticity of which he vouches: "I witnessed on our streets a few days ago what seemed to me to be an impossibility, a human being eating glass, I might say by the wholesale. I had heard of the negro before he reached our town, and I, like all others, disputed his ability to eat the glass without its doing him serious injury. When he arrived in our city I witnessed his exhibition, both in private and public, and I am now thoroughly satisfied, from careful examination of his mouth and throat, before and while eating the glass, that he eats it fairly and squarely. He is not very particular to chew it fine. I saw a piece in his mouth, after he had chewed it, one-quarter by one-half inch long, made into all kinds of shapes and sizes by crushing it with his teeth. He informed me that he had been at it for twenty years, and had never had the least discomfort from its effects. He told me that he has daily passages of glass through the bowels. He eats it in any quantity from a small piece to a whole lamp-chimney at a time, and keeps it up during the day, making his living by exhibiting his extraordinary power of eating glass."

Clinical.—Science is good, Experience is better, Art is best of all.

THE METRIC SYSTEM IN MEDICINE.

By LLEWELLYN ELIOT, M.D.,

WASHINGTON, D. C.

Being one of the pioneers in the introduction of the metric system of weights and measures into general use among physicians and druggists of Washington, I feel, to a certain extent, competent to judge the manner of its reception. When, in 1881, the writer made his first attempt in this direction, there were but few of our druggists able, without the assistance of tables and rules, to compound metric prescriptions. To this day there is an undercurrent of opposition to its adoption. Considered as a system its workings are as simple as are those of the old and familiar one so long in use; as to accuracy there is but little or no appreciable difference. For simplicity of rules for conversion and reconversion of quantities it is unequalled. Still, with all of these advantages, it will be many years before its general adoption. Its scale—deci, centi, milli, deca, hecto, kilo—is as simple of application and as easy to remember as the grains, drachms, and ounces of the old system. With the educators, medical and pharmacal, rests the ultimate success and adoption of this method of prescribing and compounding prescriptions, but compulsory measures will undoubtedly fail.

The table which is given below is one which I prepared some years ago, and has a degree of exactness which the revised or American system lacks. By reference to it we see that it is based upon .067 gm. (sixty-seven milligrammes), and to correctly follow it there must be three decimal figures. In expressing any quantity of grammes the word gramme should be abbreviated and underscored, thus, gm. The terms decigramme, centigramme, milligramme must never be used except in reading the quantity; in this way mistakes will be avoided. A good way to preserve regularity and prevent errors on the part of the prescriber, as well as on the part of the druggist, is to have a line running down the blank used, to take the place of the decimal point.

Table of Metric Equivalents.

Gr. or Min.		Gm. or C.c.	Gr. or Min.		Gm. or C.c.	Gr. or Min.		Gm. or C.c.
1/1000	=	.0001675	1/8	=	.022	22	=	1.466
1/2500	=	.00026	1/2	=	.033	24	=	1.600
1/3000	=	.00033	3/4	=	.050	26	=	1.733
1/1875	=	.00050	1	=	.067	28	=	1.866
1/1000	=	.00067	1 1/2	=	.100	30	=	2.000
1/960	=	.00065	2	=	.133	32	=	2.133
1/800	=	.00083	3	=	.200	33	=	2.200
1/600	=	.0010	4	=	.267	34	=	2.267
1/500	=	.0011	5	=	.333	36	=	2.400
1/375	=	.00134	6	=	.400	38	=	2.533
1/288	=	.0013	7	=	.467	39	=	2.600
1/300	=	.001675	8	=	.533	40	=	2.667
1/272	=	.0020	9	=	.600	42	=	2.800
1/244	=	.0025	10	=	.67	44	=	2.933
1/300	=	.0033	11	=	.733	45	=	3.000
1/256	=	.0041	12	=	.800	46	=	3.067
1/192	=	.0055	13	=	.867	48	=	3.200
1/150	=	.0066	14	=	.963	50	=	3.333
1/128	=	.008	15	=	1.000	56	=	3.733
1/96	=	.011	16	=	1.067	60	=	4.000
1/75	=	.0134	18	=	1.200			
1/64	=	.01675	20	=	1.333			

1 gr. or min.	= .067 gm. or c.c.		1/8 inch	=	.0125 mm.
1 dr.	= 4. gm. or c.c.		1/4 inch	=	.00625 mm.
1 oz.	= 32. gm. or c.c.		1 kilo	=	1,000 gms.
1 inch	= .025 mm.		1 litre	=	32 oz.

The following rules will be found of service in teaching and studying this system:

1. To convert troy grains or minims into grammes or cubic centimetres: Divide the number by 10, and from the quotient subtract one-third.

2. To convert apothecaries' or fluidrachms into

grammes or cubic centimetres: Multiply the number by 4.

3. To convert troy or fluid ounces into grammes or cubic centimetres: Multiply the number by 32.

4. To convert grammes or cubic centimetres into troy grains or minims: Add fifty per cent., or one-half the number, and then multiply by 10.

5. To convert grammes or cubic centimetres into apothecaries' or fluidrachms: Divide by 4.

6. To convert grammes or cubic centimetres into troy or fluid ounces: Divide by 32.

7. To convert inches into metres: Divide by 40.

8. To convert metres into inches: Add ten per cent., or one-tenth the number, and then multiply by 36.

510 E STREET, N. W., September 29, 1885.

THE COMPARATIVE RESULTS OF OPERATIONS IN BELLEVUE HOSPITAL.

By STEPHEN SMITH, M.D.,

SURGEON TO BELLEVUE HOSPITAL, NEW YORK.

As we drift with current events, we but imperfectly estimate the real advance which any art or science, with which we are daily familiar, has made within a limited period. It is only when we considerately pause and deliberately compare, in detail, past methods and results with those now practised and obtained, that we fully appreciate the vast changes which have so insidiously and imperceptibly taken place.

Perhaps there is no better place in which to test the progress of practical and operative surgery than the wards of Bellevue Hospital. This ancient institution has within its walls and its immediate environments all the conditions that in modern times are regarded as unhealthful and unsanitary. It was built between the years 1811–16, on the made lands of a cove of East River, without drainage, or adequate sewerage, and without regard to ventilation. During nearly three-fourths of a century the sluggish tides have ebbed and flowed through the sodden soil of its foundation, depositing far more filth than they have removed. Since its occupation it has been used for a prison, an almshouse, and a hospital. Its wards have, from time to time, been crowded with patients suffering from all forms of contagious and infectious diseases. It has been the common receptacle of typhus and typhoid fevers, small-pox, puerperal fever, cholera, and yellow fever. Although many changes have been made in its interior, yet the great and most serious defects of location and construction have remained unaltered, and may be regarded as permanent.

Bellevue may be regarded as having been a surgical hospital only since 1850, a period of about thirty-five years, during most of which period I have been personally very familiar with the practice in the several surgical divisions. The amount of surgery in the wards of Bellevue has been a gradual increase. With the removal of the New York Hospital, and during the long interval of its non-existence, the surgical practice of Bellevue became large and important, and has remained so to the present time. The surgeons of Bellevue have always ranked among the best in the city, and, as much of their practice in hospital has been public and clinical, it must be assumed that they have endeavored to the best of their ability to illustrate to their classes the highest type and best results of the science and art of surgery of their day. And yet the practice of surgery in Bellevue Hospital has, within the period mentioned, undergone so complete a revolution that one of the older surgeons would scarcely realize that he was in the same hospital where he had practised a decade ago. He would see, with horror, operations fearlessly performed that he had formerly regarded as without the pale of legitimate surgery. He would witness procedures in the after-treatment of operations which would seem to him to be fantastic, and even ludicrous. His astonishment would be extreme on finding that the first week passed without fever, and that no change in the dressings had been made. But, perhaps, the most remarkable feature of modern practice would be the rapid convalescence and final complete recovery without complication or exhaustion of ordinary operations, which formerly gave so much trouble and anxiety. To make more evident the change in practice, we may contrast in detail the several steps of operations in general, and of individual cases, the methods of treatment, and the results.

The older surgeons of Bellevue Hospital had practised in the period anterior to the use of anæsthetics. The most important general principle governing the operator was *celerity*—in order to limit as much as possible the amount of pain. Long after anæsthetics came into general use surgeons dwelt with much emphasis upon the necessity of cultivating the habit of operating rapidly. The preparations for an operation were all made with reference to this one feature. So much did this thought absorb the operator that he often became excited and annoyed by the delay. One surgeon, noted for the rapidity of his operations, was often seen, during the last moments of preparation for an amputation, to seize involuntarily the saw and move it rapidly, as if sawing a bone. Now, while every surgeon aims to diminish the period of anæsthesia, mere haste at an operation is only mentioned to be condemned. No part of the elaborate preparations are designed to render the operation simply more rapid. One thought and purpose occupy the mind of the surgeon, and that is recovery without suppuration. To this end all his preparations are made, and the entire procedure is subordinated. Formerly the surgeon prepared his instruments only by keeping them free from rust, and giving them a fine edge. When he operated the instruments were taken from the case, and, without any cleansing, were so placed that he could most readily select the one required. During the operation he laid them down, or dropped them, and without cleaning applied them again to the wound. Now instruments are not only protected from rust and all soiling and kept sharp, but long before the operation they are placed in a carbolic solution, in order that any possible septic matter on them or their handles may be destroyed.

During the operation one assistant devotes himself entirely to the duty of handing the instruments to the operator, and of receiving them from him and at once submerging them in the disinfectant liquid. To avoid the possibility of laying an instrument down on an unclean surface, and then putting it in the wound soiled, towels wrung out of the antiseptic fluid are spread around the wound.

In preparing a part for an operation, as amputation, the surgeon used to do nothing farther than, perhaps, to have superfluous hair shaved off, and that, too, often without soap and water. Patients brought directly from the street or shop, with limbs begrimed with dirt and filth, were subjected to operations without bathing. Even when there was ample time for preparation little or no thought was given to the immediate condition of the part about to be incised. The accumulated secretions of the skin, and the dead epidermis, charged with poisonous animal matters, became part of the wound and its immediate surroundings. Through this layer of filth the surgeon passed his knife into the living tissues beneath, conveying to the deepest parts of the wound matters of untold septic virulence. In this simple failure to secure ordinary cleanliness of the surface, more wounds were poisoned and induced to suppurate than from any other cause. In the closure of the wound the filthy margins were often brought in direct contact with the cut surfaces, and thus the propagation of the germs of fermentation or putrefaction were implanted in a fertile soil. Now, the greatest pains are taken to cleanse the part about to be operated upon. In addition to a general bath, the entire limb, including the hand or foot,

is washed with soap and water, with a flesh-brush, and all the hairs are shaved cleanly from the part. This washing is followed by a douche of an antiseptic solution, and then all the parts adjacent to the wound are covered with towels, wrung out of bichloride solution.

The personal preparation of the surgeon and his assistants for the operation was limited to self-protection against soiling their clothes or person. No special thought was ever given to the condition of the hands and nails. The assistants came directly from other ward duties, their hands soiled by contact with the thousand impure matters which they must handle, and with slight or no washing, engaged actively in the manipulations of the operation. Now the surgeon and his assistants take infinite pains with their hands. Soap and water and the flesh-brush are brought into active use, to be followed by a douche of bichloride solution. The nails, the most fertile source of filth in the body, are rendered scrupulously clean. Many will recall with a shudder the long claw-like nail of one surgeon, which penetrated, unwashed, every wound where he was present. Not only is no bystander invited to put his finger in the wound, but scarcely an attendant at Bellevue would allow such an intrusion.

The sponges of former times were universally believed to be the carriers of filth to the wounds, and yet little was done to purify them except to cleanse them in water. They may have been boiled at first to free them from sand, but they were not purified by any adequate means when first prepared, nor after their use in suppurating wounds. Now, the process of purification of sponges is elaborate in the extreme, and is so exact in details as to render them positively harmless in wounds.

The ordinary silk ligatures were formerly regarded as necessarily foreign bodies in wounds, and no care was taken of them to improve their condition. They were carried about in any convenient pocket, and at the operation the silk was cut of proper lengths, waxed, and then drawn through a buttonhole of an assistant, or laid on any convenient surface. Now, the ligature thread undergoes a long process of cleansing and disinfection at the hands of a chemist, and is then applied to a reel enclosed in a corked bottle filled with antiseptic fluid. From this bottle it is removed only as it is drawn out at the moment of using it. Considering the well-recognized fact that the ligature, as formerly used, was an intense irritant to wounds, it is not surprising that surgeons applied as few as possible. From time to time they resorted to other methods of closing arteries, as by torsion, or metallic wires, to avoid the use of silk. But all these devices bore no comparison to the simple and efficient antiseptic ligature of to-day. Reeled off from the bottle, clean, strong, and supple, the surgeon applies them without other limit than the complete suppression of hemorrhage.

Recognizing the silk ligature as an irritant, the surgeon always used to cut off but one end, and left the other end depending from the wound, to be removed by traction when it had finally separated from the end of the vessel to which it had been applied. And well and faithfully did the ligature meet its indications, for, during the first week, the most critical period in the history of the wound, it did not fail to induce free, and often profuse, suppuration. But now, not only does the surgeon freely apply the ligature, but he cuts off both ends, and closes the wound as completely as if there was no foreign substance left between its surfaces. Nor is he disappointed. No suppuration follows the presence of the ligatures, and union takes place as promptly as if no ligatures had been used. The operation being completed in the shortest possible time, the operator concluded by exploring all parts of the wound with his unwashed fingers. If it was a hernia, he thrust his fingers as far into the abdominal cavity as possible, and explored it freely. This act completed, it was a very common occurrence, also, for the surgeon to invite any bystander to examine the wound with his fingers, and sometimes several persons would avail themselves of the opportunity to improve their tactual sensibilities.

Many a wound, that may possibly have escaped previous poisoning at the hands of the operator and his instruments, has received its final charge of septic matters from the dirty fingers of a casual looker-on. Now, the most scrupulous care is taken to protect the wound from injury, either at the hands of the surgeon or his assistants. Exploration is cautiously made with fingers cleansed and disinfected, and even that act is completed by a douche, over the entire surface examined, of the bichloride solution. If the finger of a bystander were introduced into the wound unwashed and undisinfected, the surgeon would regard the act as probably fatal to recovery without suppuration. Hence, no one is now invited by courtesy, or to obtain an opinion, to examine the wound by digital exploration unless they have made due preparation for the act.

In closing an ordinary wound the surgeon formerly took great pains to provide for the drainage of pus. The most dependent part of the wound was left open, and all of the ligatures were drawn out at that point. The edges of the skin were brought into apposition by the interrupted suture, at intervals of half an inch, and the intervening skin was approximated by adhesive plaster. The suture and adhesive plaster were alike unprepared by any process that would relieve them of filth, and far too often both contained the germs of putrefaction. Now the surgeon employs sutures that, like the ligatures, have been relieved of all possible elements of poisoning, both in their preparation and in the method of preserving them. In closing the wound he aims to avoid suppuration altogether, and to secure the immediate union of parts. The suture being non-irritating, he freely stitches together all the deeper structures first, wherever they can be approximated, and then the more superficial parts are brought into firm and exact apposition. Instead of the interrupted suture, which leaves the wound gaping at intervals, and necessitates the use of adhesive plaster, he employs the uninterrupted, or glover's suture, which closes the wound throughout, and relieves it of all necessity of additional support. Wherever there is liability of the collection of fluid from the immediate drainage of the surface of the wound, he inserts a drainage-tube, as a temporary expedient to prevent distention of the wound, and possible putrefaction. The advantages of this latter dressing over the former are apparent. No irritant is allowed to enter the wound. The suturing of the deeper structures brings into close and permanent apposition parts that formerly separated.

The continuous suture has great advantages over the interrupted suture, especially when it is taken deeply in the margins of the wound. It not only brings the surfaces into firm apposition at the points where it traverses the wound, but by whipping the edges, in the parlance of the tailor, where it passes over the wound externally, it relieves us of the necessity of any additional supporting dressings. The advantages of this method of dressing, therefore, are great, and, indeed, vital, in the effort to secure immediate union.

The final dressing of the wound formerly was the adhesive plaster and the bandage for support and retention. The plaster was never rendered aseptic, and by its close relations to the wound was dangerous. The bandage was usually of unbleached muslin, and had no special cleansing or preparation for the wound. It may not have been harmful, but it added to the risks of infection. Now, the wound once closed, is protected from external infection by dusting the surfaces with iodoform. Then pads of disinfected materials, with iodoform sprinkled between the layers, are applied; sometimes over a large area around the wound, and in considerable numbers. The whole is retained by bandages of disinfected materials, carefully preserved in a disinfected atmosphere. The

addition of these external dressings, prepared with so much care, and adjusted with so much painstaking, has been very much criticised. It is possible that they are often unduly multiplied, but the results justify the faith which so many surgeons have in them.

In speaking of the closure of wounds, it should be stated that while the older surgeons did not close many wounds, as those of exsection, surgeons now close all such wounds. This difference in treatment is one of the most striking features in the comparison of the surgery of the present time and that of a decade past. The former surgeon prepared the wound for suppuration, the later surgeon dressed it as for union without suppuration. Both uniformly realized their expectation.

If we follow the wounds treated by these two methods from the first to the last dressings, the contrast is remarkable. If the wound were large, on the second or third day the fever formerly began, announcing suppuration, and from this date, for weeks after, the dressings were changed daily, one, two, or three times. The pus-basin, the irrigator, and the dressing-forceps were in constant demand. In many wounds the suppuration was so profuse that vessels were placed under them which received the continuous discharge. The fever generally ran high, with consequent exhaustion and depression of the patient. Septicæmia, as we now understand it, was the intermediary fever of that day, and was regarded as a usual, if not a necessary, sequel of all considerable operations. Following this fever, or rather insidiously engrafted upon it, were chills, fever, and profuse sweatings, now recognized as pyæmia, but then regarded as only another stage of surgical fever. Few indeed survived this fever; and in the diffused or metastatic abscesses revealed at the autopsy the surgeon discovered a cause of death quite beyond his power to prevent, control, or even comprehend. The vast change in the progress of operated cases during the past ten years can scarcely be realized. Surgical fever, with all its disastrous variations, is, in practice, rare in Bellevue Hospital. Pus, as an outcome of surgical operations, is a thing of the past. On one occasion last winter, a teacher in one of the medical colleges sent to the wards of Bellevue for a specimen of pus for exhibition to his class, but none was to be found in the four surgical divisions of the hospital, although there was at that time an unusually large number of wounds and operated cases under active treatment. The wound is now dressed with no expectation that fever will rise, or that suppuration will occur, or that the dressings will require renewal on account of the presence of pus. The patient sleeps and eats well from the first, and the surgeon removes the dressing, often only to find the wound united. This remark is true, not only of incised wounds, but equally of wounds of amputation, excision, ligation of arteries, etc.

If now we turn from this review of the several stages of operations in general to particular operations, we find many curious illustrations of the remarkable progress of practical surgery in this hospital. It must be understood that in every operation all of the general precautionary measures already described are scrupulously taken and carried out, and, therefore, only special differences in treatment will be mentioned.

Compound fractures were formerly regarded as proper cases for amputation, if the local injury exceeded a single fracture, with a simple penetration of the soft tissues. And even the simplest cases of compound fracture were reserved for treatment with many misgivings as to the result. The dictum of Hunter that "compound fractures commonly suppurate" was ever the guiding principle in the mind of the surgeon. If, therefore, the wound was extensive, or the bones comminuted, or a joint involved, amputation was the rule. If it were decided to endeavor to save the limb, the only measures adopted were sealing the external wound with some imperfect substance, and placing the limb in a comfortable position. The old fracture-box for the leg and the fenestrated gypsum bandage were the only measures employed. The fracture-box, with its bed of bran or sawdust, was regarded as a remarkable advance in the treatment of compound fractures of the tibia. Placed in the box, with the foot fixed to the foot-board, the wound was covered with bran, and suppuration allowed to go on *ad libitum* and *ad infinitum*. The contrivance had no merit whatever. On the contrary, it greatly aggravated the suppuration by fixing the lower fragment, while it allowed the upper fragment to move freely upon it every time the patient moved. The gypsum splint and bandage had the merit of keeping, or aiming to keep, both fragments at perfect rest. This method of treating compound fractures was a real step in advance, but it did not prevent suppuration in some measure. To-day compound fractures are welcomed to the wards of Bellevue as a class of cases which give the most satisfactory results.

Amputation is not thought of unless arteries and nerves are so far destroyed that death of the extremity must follow. Even when the wound involves a joint, the question of amputation is not more pressing. The treatment pursued is designed—1, to remove from the wound every particle of matter liable to injure the tissues and induce suppuration; 2, to place in fixed apposition all of the tissues composing the wound; 3, to cleanse and disinfect the wound, and protect it from becoming soiled during recovery; 4, to protect the wound from any movement of the parts entering into it while the process of repair is going on. The procedure, so far as concerns the wound, consists in freely exposing the injured parts by incision, removing all effusions of blood, shreds of injured tissue, fragments of bone, and then wiring the bones together so that fractured parts exactly fit each other, next stitching together all cut or torn tissues with prepared catgut thread, as far as they can be brought together; then the final closure of the wound, except where a drainage-tube may be inserted into a cavity of the deep parts; and, finally, the external antiseptic dressings and a light bandage of plaster-of-Paris, and over all a wire-gauze splint for suspension. This treatment of compound fractures is so uniformly successful that the surgeon has none of that care and anxiety after the final dressings which formerly harassed him. If there should be symptoms indicating suppuration, the dressings are at once removed, and the source of the trouble searched out and destroyed.

Amputation wounds rarely, if ever, recovered at Bellevue, except after long-continued suppuration. From the smaller amputations patients recovered in due time, but often greatly enfeebled by the drain of suppuration. The larger amputations were terribly fatal. A resident surgeon once made the statement that a recovery after amputation of the thigh had not occurred in Bellevue Hospital "since the time that the memory of man runneth not to the contrary." Though this remark was not strictly true, it had a painful significance to the surgeons of that period. Suppuration, with its sequelæ, septicæmic, pyæmic, and hectic fevers, was the scourge of the surgical wards. The open method of treatment of amputation wounds, advocated by Dr. James R. Wood, had only the merit of not confining the pus within the wounds, and of thus diminishing somewhat the liabilities of septicæmia and pyæmia. It did not prevent suppuration, the source of all the evil. The treatment consisted in closing the upper part of the wound, and placing the stump in such position that the pus flowed freely out into a vessel placed to receive it. The period of suppuration was undoubtedly diminished by this free exposure of the wound to the air, and the application of balsam of Peru, a favorite remedy with Dr. Wood. The open method was, therefore, a decided improvement upon the old method of closing wounds, but it came far short of the present method, which prevents suppuration altogether, or reduces it to a minimum. Except for the unfavorable conditions incident to the injury, amputations

are now among the most successful operations at Bellevue. Death, by suppuration and its results, does not occur.

Excision of the larger joints was formerly a most doubtful and dangerous operation. The wounds were flooded with pus for months; and if the patient survived, it was only after the most desperate struggle. The specimens of exsected joints in the Wood Museum, honeycombed with channels through which pus flowed out from the deeper parts of the wound, will be lasting witnesses to the destructive pathological processes which the surgeons of a former period could not avert, and which brought to an untimely issue the best-planned operations. In dressing exsection wounds the older surgeons made ample preparation for suppuration. The wound was left open, and the limb was placed in such position as would allow the pus to escape most freely. For months the patient lay in the same position, wasting under the excessive drain, and often having as a dreaded complication extensive bed-sores. Now the surgeon completes the operation by firmly and accurately closing the wound at all points, except where the drainage-tube emerges. This tube is used only for the temporary purposes of relieving the wound of accumulating serous fluid, and is soon removed. As a rule, excision wounds now do not suppurate; union takes place by rapid and healthy granulation.

During the past year or two we have had under observation many cases of excision of the knee-joint, the hip-joint, the elbow-joint, and the ankle-joint, which have been repaired without suppuration. In one instance of an old and destructive inflammation of the ankle-joint the articular ends of the tibia and fibula, the surfaces of the astragalus and os calces, and all of the surrounding tissues had to be thoroughly scraped to remove the dead bone and fungous granulations. When the cavity was prepared for dressing it was enormous. But as all diseased structures seemed to be removed, and the wound appeared everywhere clean, it was dressed for union without suppuration. The wound did heal without other suppuration than a slight amount of pus, which discharged from a small carious surface. The health of the patient began at once to improve, and in due time she was about the ward, on crutches. We may now say of excisions as of amputations, that they are regarded as simple and very safe operations.

The ligation of large arteries was formerly justly estimated as a very serious operation. The common silk ligature, prepared by unwashed hands, was left depending from the wound. To do its work properly it must in due time sever the strangulated artery by the ulcerative process, and then be removed by traction. With the keenest and often most painful anxiety, the surgeon daily watched the wound to note the amount of suppuration, and gently tested the firmness of the ligature. If after the separation of the ligature the suppuration diminished, and finally ceased, the surgeon was happy and boastful of his success. But far too often the suppuration did not diminish, and to the dismay of the surgeon a slight oozing or gush of blood indicated to his practised eye a fatal issue by secondary hemorrhage.

How desperately yet vainly he struggled against fate, by resorting to pressure, position, styptics, etc., the older surgeons can alone realize. The repeated hemorrhages, or uncontrollable outburst, at length placed the case in the category of unsuccessful operations. Now, how completely are all the conditions of the operation changed! It is no longer necessary to divide the artery by the ligature to accomplish our object, and thus endanger life by hemorrhage; but, on the contrary, we seek, while we interrupt the circulation sufficiently to effect our purpose, to strengthen the artery by our operation. The indications now are the opposite of those which before obtained. The ligature now selected is non-irritating, and preferably absorbable, as catgut. When applied, it may, or may not, divide the internal coats of the artery. In either case the wound is completely closed and no suppuration occurs. In the repair the artery enlarges externally at the seat of the operation by nutritive action, while the coagula organizes internally and closes its calibre. Secondary hemorrhage after the ligation of arteries has, therefore, become an incident of the past. The conditions no longer exist which make it possible. Ligation of the common carotid is a familiar operation at Bellevue, and was often performed with great skill by Dr. Wood, who published an elaborate monograph on that subject. I aided him in the examination and collection of cases, and in the preparation of the text, and was impressed with the destructive effects of the ulcerative process which attends the separation of the ligature. Some time since I had occasion to ligate this artery, and applied the catgut ligature, cutting both ends close to the knot, and closing the wound perfectly. Union promptly followed, and nothing farther was seen of the ligature. The patient died at the end of two months of cancer of the mouth and pharynx, and the autopsy revealed an enlargement of the artery at the seat of the ligature to twice its normal size, by a ring of new tissue completely encircling it. On incising the artery at this point, the remains of the ligature were found in this ring, and the coagula had organized and closed its cavity permanently. It was evident that the ligature had greatly strengthened the artery instead of destroying it, as in the old operation.

It follows that, if the major operations are now performed with so much success, the minor operations are correspondingly successful. If we take as an example the treatment of cold abscesses, the improvement is very noticeable. Formerly a cold abscess unconnected with bone, as in the thigh or on the back, were preferably allowed to open themselves. If the surgeon ventured to operate, he usually made a "valvular incision," and allowed part of the contents to flow out, and then closed the wound. This operation was repeated many times. When aspiration was introduced, it was regarded as a great advance. The fear of the surgeon was that air would enter the abscess cavity, and set up active suppuration. I recall a case of large abscess of the back, in a young woman, which, after consultation and much deliberation, Dr. Van Buren ventured to puncture directly. The interest taken in this bold operation was very great, and the progress of the case was watched with much anxiety by the operator. Profuse suppuration followed, and the patient nearly lost her life. Now these abscesses are promptly cured and without suppuration, by opening them freely, and, with the curette, scraping out all the old granulations and diseased tissues; then thoroughly cleansing the cavity with bichloride solutions, and finally pressing the walls gently together with disinfected sponges and bandages, or other antiseptic dressings. The walls of these abscesses, sometimes of enormous size, and many square feet of surface, promptly unite, and often under the first dressings.

And not less important is the change in the treatment of abscesses connected with carious bone. Abscesses in the lumbar and femoral regions, caused by caries of the spine, were once greatly feared at Bellevue.

Billroth's advice was very rigidly followed, viz.: "If the abscess comes from a bone on which an operation is impossible or undesirable, do not meddle with it, but be thankful for every day that it remains closed, and wait quietly until it opens, for thus there will be relatively the least danger." Now these abscesses are immediately opened and kept thoroughly cleansed, together with their sinuses, by bichloride solutions, with a marked diminution, and in some cases, a complete suppression of suppuration. In several instances of both lumbar and femoral abscess from spinal caries incisions have been freely made, the pus evacuated, and by means of the soft rubber catheter gently passed along the sinus, the carious abscess itself has been thoroughly and repeatedly cleansed and disinfected with carbolic or bichloride solutions, followed by rapid diminution and final complete cessation

of suppuration. Meantime, the patients have rapidly recovered from the symptoms of blood-poisoning from which they have been suffering.

At a recent period a method of treating large abscesses and diffused collections of pus in cellular tissue by the introduction of large perforated drainage-tubes was practised. Through these tubes the antiseptic solutions were frequently injected, with a view to irrigate the diseased surfaces and tissues. It was a most unscientific method, and was soon abandoned. Instead of it, we have the present rational practice of carefully opening all collections of pus, cleansing the cavities, removing all granulations and other diseased tissues, and closing the wound permanently. The former method often resulted most disastrously, the present never fails of complete success when properly performed.

Perhaps the most marked illustration of the great improvement in operative surgery in Bellevue may be found in the unvarying success which attends the treatment of simple fracture of the patella by wiring together the fragments. It was eminently fitting that this operation, so novel and startling as to be received with almost universal ridicule by older surgeons, should have first been proposed by the great apostle of antiseptic surgery. By proposing and successfully executing this operation, he expressed his faith in his teachings in form more emphatic and convincing than language could. This procedure does, indeed, embody the very spirit and genius of the surgery of to-day, viz.: Boldness to audacity in the conception of an operation, and conservatism the most absolute in the method and means employed in executing it. And yet this operation is now accepted as legitimate in Bellevue, and is of almost weekly occurrence in one or the other of its surgical divisions. And no operation, so inherently dangerous when performed according to old methods, has ever proved more successful. It has now been performed in more than a score of cases without an unfavorable result.

Though this paper was to be limited to a review of the comparative results of the ordinary surgical practices of Bellevue, formerly, and now, with a brief commentary upon the means and methods employed, I cannot pass unnoticed the success which attends the practice of gynecology in that hospital. The surgery of the pelvic organs of the female is based on the same principles as those which govern the general practice of surgery in Bellevue. And the results are equally remarkable.

Septicæmia and pyæmia are almost unknown in the pavilion devoted to this branch of surgery, and recovery after operations is rapid and complete, unless the case is complicated with conditions quite beyond control. The following statistics show the great success of operations in this branch of practice at Bellevue. Dr. Wylie states that since November, 1883, he has performed laparotomy thirty times, chiefly in the Marquand and Sturgis pavilions, with five deaths. Of the cases proving fatal, two were hysterectomies, one for cancer of the uterus and the other for a myoma weighing fifty pounds; two were cases of pelvic abscess, complicated with purulent collections in the fallopian tubes. All of the cases of ovarian cysts recovered.

In reviewing the surgical practice of Bellevue, it is not difficult to determine the essential feature of the present methods as compared with those of the past. Cleanliness is the one great object sought to be attained in all operations. Whatever may be the final conclusion of scientific students as to the cause of putrefaction in wounds, practically it is determined that the surgeon may, with the most absolute certainty, protect an ordinary open wound from suppuration. To effect this object he finds that he has simply to resort to those measures which are known to secure perfect cleanliness of the wound. The agents now relied upon and found efficient are: 1. Soap and water to external parts. 2. Carbolic solutions for the instruments. 3. Bichloride solutions to all surfaces and tissues. 4. Iodoform for external dressings. We may summarize the conditions regarded as essential to success as follows, viz.: *A clean operator; clean assistants; a clean patient; clean instruments; clean dressings.*

COCAINE IN BONE SURGERY.

By MILTON JOSIAH ROBERTS, M.D.,

PROFESSOR OF ORTHOPEDIC SURGERY AND MECHANICAL THERAPEUTICS IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, VISITING ORTHOPEDIC SURGEON TO THE CITY HOSPITALS ON RANDALL'S ISLAND, ETC.

To Dr. C. Koller, of Vienna, the civilized world is indebted for the practical suggestions which have led to the widespread use of cocaine as a local anæsthetic. The results already obtained by numerous clinicians and scientific observers, along the line of research originally pointed out by Koller, form a phenomenal chapter in the progress of knowledge regarding relief from pain. But it has been in the application of the drug to mucous membranes that its most brilliant and beneficial effects have been obtained. The results of its hypodermatic use in other localities, though exceedingly gratifying, did not give promise of all that was desired in the way of a local anæsthetic. Thus used its effects were so transient and limited in extent as to require the administration of an excessive amount of the drug, which in turn gave rise to unpleasant constitutional disturbances.

It remained for the genius of Dr. J. Leonard Corning,[1] of New York, to point out and experimentally demonstrate the value of a fundamental departure in the method of its administration, which is to yield by far the most extraordinary practical results yet obtained in its local use as an anæsthetic.

In brief, Dr. Corning's experiments showed "that simple arrest of the circulation in the part, shortly after injecting the anæsthetic, is sufficient to prolong and intensify the anæsthesia." It is clear, therefore, that circulating blood is the active agent in washing the drug out of the tissues into which it has been injected, and thereby shortening the period of anæsthesia.

September 30, 1885, I performed a minor surgical operation in soft tissues, upon a delicate young lady patient in my office, Dr. Corning kindly administering the local anæsthetic according to his method. The profound anæsthesia produced, the small amount of cocaine used, and the great duration of its effects were gratifying surprises to me. For the first time it now seemed probable to me that in the use of cocaine according to this method, I was shortly to realize the practical execution of an idea which I have long cherished, viz., the local anæsthetization of bone and overlying soft tissues.

On the following day (October 1, 1885), having pondered over the subject, I ventured to predict, at my clinic at the New York Post-Graduate Medical School and Hospital, the successful application of this method in bone surgery; I proceeded to detail, on that occasion, the plan which I would try when the first opportunity presented itself. I called attention to the great convenience of the local anæsthetization of bone in the elaboration of the line of work proposed by me in February last.[2]

Assisted by Drs. George R. Elliott and Charles E. Bruce, on Wednesday, October 14, 1885, at the New York Post-Graduate Medical School and Hospital, I proceeded as follows, with a young lady brought to me by Dr. Martin Burke, of this city: She was twenty-seven years of age, and suffered from chronic disease of her elbow-joint of several years' standing. Pus was being discharged from three openings about the joint. The tissues round about were infiltrated with inflammatory

[1] On the Prolongation of the Anæsthetic Effects of the Hydrochlorate of Cocaine when Subcutaneously Injected. An Experimental Study. By J. Leonard Corning, M.D., *vide* New York Medical Journal, September 19, 1885.

[2] The Exploration, Excavation, and Illumination of the Interior of Bones in any Part of the Body. Being Remarks addressed to the Clinical Society of the New York Post-Graduate Medical School and Hospital, February 21, 1885.

products and œdematous. The patient came into the operating-room fully expecting to have ether administered, and when told that a local anæsthetic was to be used, was so apprehensive of pain from the proposed operation, that it was with great difficulty that she could be persuaded to get upon the operating-table. She was weak from hunger and anxiety regarding the operation. An ounce of brandy, in water, was given her.

Having provided myself with a hypodermic syringe, loaded with a five per cent. solution of Merck's cocaine, I began puncturing the skin, injecting at each point about one minim of the solution as near the surface as possible. The area over which these injections were made was an extensive one, covering a segment of the limb from about three and a half inches above the joint to an equal distance below the joint, and involving its entire circumference. It was observed that the diffusion of the anæsthetic drug was very slow, on account of the infiltration of the tissues with inflammatory products, thus interfering with the local circulation, and consequently with the distribution of the drug. About twenty punctures were made, and a like number of minims of the solution, representing a grain of the drug, injected. At the expiration of about fifteen minutes an Esmarch's bandage was applied to the limb, extending from the tips of the fingers to within three and a half inches of the elbow-joint. The object of this was, in the first place, to get as much blood as possible out of the limb prior to beginning the operation, and, in the second place, to relieve the patient of the sensation of engorgement of the limb when subsequently girdled with an elastic band above the joint.

Superficial anæsthesia having been secured, the deeper tissues were penetrated by the needle, and about two minims of the solution injected at each point. The patient no longer winced under the repeated introductions of the needle. The evidences of profound anæsthesia were now manifest to all present, though the patient was still exceedingly apprehensive of pain. The arm was next encircled with a strong elastic band, at a point about four inches above the elbow-joint. With a scalpel a five-and-a-half inch longitudinal incision over the external condyle of the humerus and to the outside of the olecranon process was made, in order to connect two openings from which pus was being discharged. The patient's head being turned, she did not realize that the knife had been used.

Having reached the bone in the neighborhood of the external condyle, the needle of the syringe was introduced under the periosteum in several places and minim injections of the cocaine solution made.

For the purpose of locating the bone lesion and determining its extent, I introduced a drill one-sixteenth of an inch in diameter into the head-piece of my electro-osteotome, closed the circuit, and rapidly penetrated the condyles of the humerus. No pain whatever was experienced by the patient. As the drill passed transversely through the lower end of the bone, I could easily appreciate that it had entered a cavity. Upon withdrawing the drill, the débris lying in its groove was, at my request, immediately submitted to microscopical examination by Dr. George R. Elliott. He reported that the specimen removed was composed of bone spiculæ, fat-droplets, a few red blood-corpuscles, and numerous pus-cells. The lacunæ in the particles of bone removed were variously arranged in comparison with each other, and presented an abnormal appearance. In many of the minute spiculæ of bone the canaliculæ were absent and replaced by fat-droplets. In small areas also the intervening substances was entirely composed of fat-droplets. Fat-droplets were also to be seen in the corpuscles occupying the lacunæ. These findings were regarded as indicating beyond all doubt the existence of a carious process.

In order to explore the site of disease more thoroughly, I introduced a quarter-inch drill into the electro-osteotome and followed the path made by the smaller one through the bone. Absolutely no pain was experienced by the patient in the passage of this large drill. Upon its withdrawal and examination of the cavity by means of a probe it was found that the dissolution of the internal condyle of the humerus was nearly complete. The cavity was cleaned out, the soft tissues on the inner aspect of the arm punctured, and a drainage tube introduced.

It was still uncertain, however, whether the other bones entering into the formation of the joint were involved in the carious process. To determine this I again made use of a small drill, transversely penetrating the ulna on a level with the coronoid process. Again my patient manifested no discomfort. The débris lodged in the groove of the drill was at once kindly examined microscopically, by Dr. Elliott. He found it to be composed of small bone spiculæ which presented a perfectly healthy appearance. No further exploratory punctures of bone were deemed necessary. A second drainage-tube was introduced through an opening which existed on the lower posterior aspect of the arm and was passed through a counter-opening on the upper and inner aspect of the forearm. The longitudinal incision in the soft parts was closed by interrupted sutures, antiseptic dressings applied, and the patient permitted to go home.

Clinical Department.

LAPAROTOMY FOR ILEUS.

Dr. Henry F. Beam, of Johnstown, Pa., reports the case of a lady, aged forty-eight years, who had been confined to bed for two months suffering from an obscure trouble. She had jaundice, the pulse was small and rapid, the temperature was 101° F., the patient suffered intense pain, and had fallen away forty pounds in weight. For three days she had had occasional attacks of stercoraceous vomiting. Palpitation of the abdomen caused great pain, especially in the right iliac region, where there was a prominence resembling a hernia, beneath which could be felt a hard, round substance. An attempt to move the bowels by enemata was unsuccessful. It was finally determined to operate, and accordingly, chloroform having been administered, an incision two inches in length was made over the point of swelling. The ileum was opened at its point of junction with the cæcum, and the knife immediately struck a hard body. The incision being prolonged, a calculus the size of an English walnut was removed. This was found on section to consist of a small nucleus, the size of a buckshot, surrounded with concentric layers of a material resembling lime, about one-sixteenth of an inch in thickness. The patient made a good recovery.

MILK DIET IN THE ALBUMINURIA OF PREGNANCY.

Dr. L. Swartwout, of Prospect, N. Y., was called to see a patient in the eighth month of pregnancy who was suffering from clear evidences of albuminuria. She was put under suitable treatment, and was restricted to milk diet. The general condition was much improved, and at the expected time the patient was delivered of twins. There were no signs threatening eclampsia during labor, and the woman is now doing well.

COCAINE IN HAY FEVER.

Dr. J. W. Stickler, of Orange, N. J., writes that he has suffered from hay fever for six years, and never succeeded in materially mitigating the severity of the attacks until he used cocaine.

"The symptoms were violent, and repeated sneezing, profuse discharge of a thin watery fluid from the nostrils, itchiness of pharynx, nose, and eyes; headache, impaired appetite, and restlessness at night. While suffering from all these symptoms I sent for a bottle of soluble hypo-

dermic tablets of cocaine, 1.25 grain each, and introduced three into each nostril, keeping them in position, and favoring rapid solution by forcing the alæ against the septum nasi with a handkerchief. As soon as the tablets were dissolved, I snuffed the solution up the nostril in order to secure a thorough application of the drug to the nasal mucous membrane. After using the first six tablets I experienced great relief, and after using fifteen or twenty I was as free from hay fever as I think it possible for anyone to be. I used two bottles full, and then discovered that the disease needed no further treatment, as there was no disposition to sneeze, the nerves of the nasal mucous membrane having become non-susceptible to the various irritants which before had caused so much trouble.

"I wish to say that cocaine tablets are worthless as a remedy for hay fever. I say this because they were recommended as a good 'article,' but careful trial failed to show any cocaine effect."

TREATMENT OF ACUTE EPIDIDYMITIS WITH SUBNITRATE OF BISMUTH.

Dr. J. A. Comingor, Professor of Surgery in the Medical College of Indiana, writes: "In your issue of July 11th a paragraph is published from the *Gazetta Medica di Roma*, setting forth the value of Fuller's-earth in the treatment of acute epididymitis. For several years and in many cases, both in hospital and private practice, I have been treating this affection with subnitrate of bismuth with results nearly identical with those claimed for Fuller's-earth. Under its application, pain is speedily relieved and tenderness and swelling subside in a short time. In fact, its action has been so uniformly beneficial I have not found it necessary to use anything else in ordinary cases. I direct it to be used as follows, to wit.: Bismuth in indefinite quantity, water sufficient to make a paste about the consistence of thick cream, and with a large camel's hair brush paint the scrotum two or three coatings, and repaint at intervals several times daily. To make the directions more definite, take bismuth and water in equal parts, mix, and apply as above. For the purpose of taking the weight off the cord and blood-vessels I order some sort of scrotal suspension; if the ailment is severe enough to bed the patient, a broad strip of adhesive plaster or bandage fastened across or around the thighs, with sufficient padding under the scrotum and contents to elevate above the level of the body to favor the return of blood, will be found serviceable. This method of treatment, in my hands, has been so beneficial and satisfactory I have for several years thought I ought to give it to the profession.

"As to its mode of action I am by no means clear. I have given it a great deal of thought, and have theorized in a variety of ways without being able as yet to reach a satisfactory solution of the question. In the meantime I have observed on making the application on the smooth shining surface, that scrotal corrugation and shrinkage, with alleviation from pain, immediately followed. Now whether these effects are the direct result of the astringent and metallic properties of the agent, or whether they were due to the mere protection given the sensitive surface from the air, I know not. But that it is highly serviceable I verily believe."

Salicylic-Acid Suet in Hyperidrosis.—The reports of the German army-surgeons on experiments recently made with salicylic-acid suet agree in recommending its use as a remedy for extreme sweating of the feet. It is composed of 2 parts of pure salicylic acid to 100 parts of best mutton suet. The Minister of War has, therefore, permitted the introduction of this preparation into the army medical stores, for the benefit of soldiers suffering from sweating of the feet or soreness from riding.

Progress of Medical Science.

Alleged Abortive Treatment of Trichinosis.—Dr. Gottlieb Merkel (*Deutsch. Arch. für klin. Med.*, xxxvi.) reports the case of a man who had eaten sausage containing trichinæ. He was admitted to the hospital twenty hours afterward, and was at once given about ten ounces of compound infusion of senna. Encysted trichinæ were found in the latter portions of the stools. The following day he was given fifteen tablespoonfuls of glycerine, which produced no other unpleasant results than dryness of the mouth and thirst, which was appeased by taking a little seltzer water. Nothing was found in the urine. On the third day the patient left the hospital. He continued well, while those who had eaten the same sausage at the same time were very ill. Glycerine was recommended by Heller ("Ziemssen's Cyclopædia," vol. iii., p. 643), who says that it caused the shrivelling and destruction of the trichinæ, by depriving them of water.

Pneumonia Treated by Intraparenchymatous Injections.—Lépine presents an argument in favor of the local treatment of fibrinous pneumonia by intraparenchymatous injections (*L' Union Médical*). If, says the author, an injection of a few cubic centimetres of a very weak aqueous solution of corrosive sublimate be made into the hepatized lung on the third or fourth day of the disease, in three or four places equidistant a few centimetres from one another, and preferably at the periphery of the lesion, with a view of preventing the extension of the disease, the following phenomena are observed. 1. At the seat of infection an immediate diminution of the crepitant râles and tubular breath-sounds, which are in part replaced by respiratory silence and some larger râles. 2. Sometimes, later, a transient exacerbation of the temperature of the body. 3. The next day a great improvement in the general condition, and notably a precocious defervescence. 4. A resolution which, to judge by the persistence of the harsh breathing, especially in the hepatized parts that have not been treated, takes place very much earlier than would have been the case under ordinary circumstances. As to the relative innocuousness of the intrapulmonary injections in the doses employed (twenty to twenty-five grammes of one in forty thousand solution of bichloride of mercury), when care is taken to keep away from the large vessels at the hilus of the lung, and not to penetrate the lung more than three to four centimetres, M. Lépine urges that he has not lost a single patient, and has not had one accident. The only inconvenience is the pain, but this is not great, and may be still further relieved by adding morphia to the solution. After the introduction of the sharp needle, and before the syringe is fitted on, a few drops of blood are allowed to escape; the injection must not be delayed, or the needle will become plugged. When the needle is inserted into healthy lung, or into tuberculous lung, it does not, as a rule, yield blood. In the healthy lung such injections produce sufficiently defined lesions. Experiments on the lungs of healthy dogs showed that at the site of injection of a rather stronger solution than that mentioned above there was a circumscribed and indurated area, which was made up of blood and congestive œdema. The lesions were less marked with the one in forty thousand solution.

Division of the Supra-orbital Nerve for Traumatic Cephalalgia.—An Amsterdam medical journal relates the case of a young man who received a blow on the forehead, which was followed by a tender swelling over the supra-orbital notch, and by intense general headache, so that he was unable to obtain any sleep at night. Last April Professor Wurgman divided the supra-orbital nerve just above the notch, with a fine tenotome introduced under the skin. This operation relieved the pain almost entirely; the swelling, also, almost disappeared. Anæsthesia was, however, produced over a surface of the extent of a hand's breadth above the orbit, and this has continued unchanged up to the present time.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

A CLINICAL STUDY OF CANCER.

THE publication of the records of the late Dr. Willard Parker on the subject of cancer is of particular interest. They reach back to a period nearly three score years ago, when there was almost an entire absence of definite knowledge respecting the histology of malignant neoplasms. The fact was not then recognized that the infiltration of an organ with carcinomatous elements might be very extensive before any outward manifestations of the disease presented themselves. Also many tumors were considered malignant, *e.g.*, adenoma, which our later researches and observations have lifted out of this category.

This frank statement of the views entertained by the profession half a century ago somewhat weakens, we think, certain conclusions which Dr. Parker drew from his clinical experience, that is, conclusions affecting the distinction of cancer from other malignant growths. In all cases of tumor our problem is primarily to discover its nature. The pathologist relies upon the microscope. Many a surgeon with years of experience relies mainly on the clinical history. In perhaps the majority of cases the conclusions of both are in unison, though reached from different premises. We believe that most men would, in a disputed case at the present day, decide with the pathologist rather than with his opponent. In other words, according to our present knowledge of tumors, any classification of tumors must have, to be accredited with value, an anatomical basis.

Now, in no small number of the three hundred and ninety-seven cases of mammary cancer (?) in the record under discussion, the data given are not sufficient proof to the investigator that the disease really was mammary cancer. No one doubts that such a diagnosis was conscientiously made in every case. All cases seen were not operated upon, however, and many passed out from under observation. Their ultimate fate is unknown. The correctness of some of the diagnoses is at least a debatable point, because the cases were not subjected to the test which we now regard as necessary for confirmation—*i.e.*, microscopical examination.

When we come, however, to that part of the work treating of the causes of cancer, its increasing prevalence, and its geographical and social distribution, we touch upon matter that is really valuable. Of the 397 cases, 253 were in married women, 55 in single, and 89 in widows; of the married and widows 37 had had one child, 240 two or more children, 58 were childless, and of 7 there is no record. The greatest number of cases in any five years, of ages reaching from twenty-five to eighty, was 80 cases between the ages of forty-five and fifty. The left breast alone was involved in 189 cases; the right alone in 174; both in 14; no record, 26. In regard to the relation between tubercle and cancer, Dr. Parker regarded the views of Bennett essentially true. "Taking then the products of simple inflammation (say pus) as a standard, we cannot fail to remark that, while the cell-development of tubercle is below, that of cancer is above the standard; one is deficient in the power of development, the other possesses this power in excess. It seems to me to be probable that tubercle is connected with some derangement of the function of primary, and cancer with some derangement of the function of secondary digestion."

The effective causes of cancer are grouped under four headings: first, luxurious living, and particularly excess in animal food, and facts are adduced showing that the disease has increased in frequency *pari passu* with the march of civilization; second, local irritation of an epithelial surface, particularly in mammary growths; the pressure of a corset against a breast which has suffered from some disorder of lactation; third, mental affliction, as predisposing to a condition of low vitality from nervous depression; fourth, dysmenorrhœa and other uterine irregularities. From these etiological factors some leading principles of treatment are deduced. "There is such a consensus of opinion as to the advisability of early removal of the growth that discussion of this subject would be useless." In order to forestall the development of the disease, we should avoid "unnecessary luxury in the mode of living, especially abstain from food rich in nitrogen. Urge your patient to take sufficient exercise; point out to her the necessity of cleanliness and of avoiding all articles of dress that would induce irritation of the skin. Persuade her to cultivate cheerfulness of disposition and regulate her various functions, particularly that of menstruation."

Dr. Parker does not admit the heredity of the disease: "Looking at the incurable nature of the disease . . . and the time during which it has existed, we could hardly expect a single member of a civilized community to have escaped, were the disease hereditary." He recognizes the fact that there are in some families several cases of cancer, "a fact pointing strongly to some common cause—if not to inheritance, then to habits and modes of living which have been practised by members of the family and which are sufficient to induce the disease."

THE EMPLOYMENT OF THE HIPPURATES OF LIME IN THERAPEUTICS.

M. V. POULET, a French physician, of Plancher-les-Mines, calls attention to the very superior powers of the hippurates of lime and of lithium in the treatment of many disorders of assimilation.

To begin with, M. Poulet announces that the principal acid of the gastric juice is not hydrochloric, as generally taught, but is *hippuric acid*. Like all scientific Frenchmen who believe that they have discovered something, M. Poulet feels no wavering doubts about his results, but states that he has "demonstrated peremptorily" that the

acid principle of the gastric juice is no other than hippuric.

Starting with this new physiological dogma, M. Poulet reasoned that salts formed with the hippurates would be very soluble and efficient. He, therefore, had prepared a hippurate of lime, and has used this extensively for several years (*Gazette hebdom. de Med. et Chir.*, 1884, and *Bulletin Général de Thérapeut.*, August 30, 1885).

The utility of the lime salts in many disorders is admitted. Dr. Poulet, however, contends that the practice of giving them in strongly acid media, as at present is done, works eventual injury. On the other hand, Professor Sansom, of Grignon, shows that phosphate of lime given undissolved passes unchanged through the intestines. The problem, therefore, is to get a lime-salt which will be easily absorbed and yet will do no harm by reason of the excessive acidity of the vehicle. This salt has been found, it is thought, in the hippurate of lime. M. Poulet advises that the rachitic, the scrofulous, the phthisical, persons suffering from osteo-malacia, or from ununited fractures, also infants with imperfect dental development be given hippurate of lime in combination with phosphate of soda. In this way both lime and phosphorus are taken and assimilated.

The hippurate of lime, according to the enthusiastic Dr. Poulet, possesses wonderfully specific properties: 1, Against affections of the urinary passages; 2, against affections of the liver; 3, against certain diseases of the skin and mucous membranes; 4, against a great number of diseases of the stomach and intestines; 5, against diabetes, and 6, against chronic rheumatism and gout.

In subacute cystitis and in lithiasis the hippurate given in the form of a syrup is recommended.

In diseases of the skin dependent upon the tuberculo-scrofulous or upon the neuropathic diathesis the hippurate is believed to work many cures. Poulet cites some instances in which diabetes was much improved by his remedy.

It would be useless to catalogue all the disorders in which the wonderful hippurate is indicated. In the main they are disturbances in assimilation, and are disturbances in which some mineral food is needed by the organism. It is quite possible that M. Poulet has obtained a very digestible mineral preparation, and one which deserves a trial on that ground. His claims for its wonderful efficacy, however, are extravagant and ill-founded.

OX-GALL AS AN ANTIPYRETIC.

Bile in the form of inspissated ox-gall has been alternately highly praised and sharply condemned as a therapeutic agent. Rossbach and Nothnagel state dogmatically that ox-bile when introduced into the stomach neutralizes the acidity of the gastric juice, precipitates the pepsin, and causes digestive disturbances. Other authors have regarded bile as a bitter tonic and laxative. Bonorden claimed that it reduced the action of the heart. Locally he used it with great success in the treatment of hypertrophies. It has also been employed in cancer, diarrhœa, constipation, and especially in conditions in which there is supposed to be a deficiency of biliary secretion.

The adult secretes about three pints of bile daily, of which the solids amount to between four and five ounces. The potent medicinal factors in these solids are probably the alkaline bile salts, which make up more than half the bulk and amount to several ounces daily. Cholesterine, an active poison, is also present in a very small proportion.

The ordinary dose of inspissated bile is from five to thirty grains, the large doses generally causing digestive troubles. It can be readily seen that these amounts are very small compared with the normal amount of daily secretion, even assuming that the bile ever gets unchanged through the stomach. There is, therefore, no very good reason, *à priori*, for supposing ox-gall to have a supplementary value in deficient action of the liver. Its value must be established empirically.

In the *Bulletin of the Clinical Society of the Post-Graduate Medical School*, Dr. George G. Van Schaick makes an ingenious and plausible plea for the use of ox-gall in the treatment of typhoid fever. It is given in doses of ʒ ij. to ʒ iij. daily. Under its use he believes that the fever is reduced, and the symptoms ameliorated. Three cases are given in illustration, one of which seems to have some value. Ox-gall has been used by other physicians in this city as an antipyretic, and in cases of deficient biliary secretion with, it is claimed, good results.

AMERICAN AND GERMAN METHODS OF VACCINATING.

The question whether one or several pustules should be made in vaccinating is one that is hardly raised at all in this country. Even in the elaborate and careful article upon the "Technics of Vaccination," by Dr. Foster, in "Pepper's System of Medicine," no reference is made to the matter. Yet it is well known that the profession in Germany have very settled convictions that several pustules should be made. The German Commission, which met a year ago at Berlin to discuss and formulate conclusions upon the subject of vaccination, took up, among other things, this point. "In what relation," it was asked, "does the number of vaccinia pustules stand to the protective influence of the vaccination?"

According to Dr. R. Koch, out of 703 small-pox patients, in the Stockwell Hospital, there died, of those having no scars, 47 per cent.; of those having poor scars, 25 per cent.; having one good scar, 5.3 per cent.; having two good scars, 4.1 per cent.; having three good scars, 2.3 per cent.; having four or more scars, 1.1 per cent. From this it would be inferred that a person having four scars on his arm is almost certain, even if he gets small-pox, to go through it safely. Koch himself takes the position, positively, that the protective power of vaccination is in direct relation to the number of vaccinia pustules.

Professor Grossheim cited cases to show that in revaccination the virus "takes" less often on those who have several scars. Similarly, Siegel found that among children presented for revaccination, the successes were the rule if the child had but one scar, and the exception if it had four to eight.

Arnsperger had observed during a small-pox epidemic that the protective influence of the vaccination increased with the number of the scars.

On the other hand, Reissner did not observe much difference. In revaccination of patients with one scar he got 96 per cent. of successes, while of those with two or more scars he got 94.7 per cent. of successes.

There is evidence in English statistics that persons having a number of scars are more surely protected against variola. It is true, however, that in England more than in Germany, these scars represent several successive vaccinations.

The conclusion of the Commission referred to was that two was the minimum number of pustules to be made in a protective vaccination. Professor Eulenberg even urged that the minimum should be three.

Here are conclusions quite opposed to American practice, and they are worthy certainly of attention.

MIRACLE CURES.

The latest miracle cure, as far as we are aware, has been performed at the shrine of St. Anne de Beaupré, in Canada. A cripple (of what variety not stated) had restored to him here the strength of his limbs, and, after discarding his crutches, left the place indulging in profuse encomiums of the Saint, and decidedly uncomplimentary remarks about the doctors at home who had failed to relieve him. Unfortunately the accounts that reach us from time to time of these miracle cures generally come from regions somewhat removed from any scientific centre, hence a careful investigation of the alleged facts is not undertaken, and does not appear to be encouraged. When we consider, however, that in the town farthest removed from superstition, and the favored home of culture, the "mind cure" is now in apparently fairly successful operation, we are led to inquire whether the saints and transcendentalists have not some common mode of effecting cures. It appears indeed, that the relief experienced is always in direct ratio to the capacity of faith in the individual, and the first and essential quality of being cured is for the unfortunate sufferer actually to believe that he is cured. Persons who have no confidence in the good offices of the Saint, or the benign influence of the mind cure, had better stick to drugs and potions, as otherwise they will perforce experience no amelioration of their ailments. We do not wish to deny that relief is sometimes experienced in a certain class of cases by apparently occult influences, but a perfectly natural explanation can readily be given for these so-called supernatural occurrences. It is solely the power and force of an intense faith that works the cure, and not any outside miraculous influence. It is entirely possible in certain individuals for this kind of faith to cause such a condition of mental exaltation and enthusiasm as to overcome long-seated functional trouble. The body appears to be transformed under the influence of the mind, even to a certain extent to the checking of morbid processes. Exactly the way in which the mind can thus influence bodily functions we do not know, but we have here a satisfactory and natural explanation of these miracle cures. Let us not, then, deny the possibility of some of the cures, although they generally come from ignorant and untrustworthy sources. If in the excitement of battle soldiers may receive painful wounds without being conscious of their existence, why may not a similar state of exaltation, produced in a different way, and with the addition of expectancy, sometimes be sufficient to remove a neuralgia?

If the mind by any means can be raised to a certain pitch, pain, danger, and death itself become trival to the body. History is full of examples of this fact. Cromwell's Ironsides, or Arabian spearmen throwing their lives away on English bayonets, alike exemplify this condition. The utmost self-confidence being engendered, the greatest obstacles appear as trifles to be overcome. Why may not a condition of exhilaration and confidence produced by an intense superstitious faith be at times sufficient to send an impulse through a nerve that for some reason has long ceased to respond to natural stimulation? We must note, however, that these cures take place apparently only in functional and subjective troubles. Modern miracles are never constructive. We have yet to hear of the saint who could restore a leg that had been amputated at the hip-joint; not a few happy individuals, however, with two limbs in such a condition of defective innervation as to preclude walking without crutches, have suddenly had their locomotion completely restored. If carefully followed up, we fear that most of these cures, except in cases of trivial functional derangements, would be found to suffer relapse when the mental confidence that engendered them had somewhat subsided. The most diverse agencies, from a patent liver regulator to a kidney or corn cure, doubtless produce a mild subjective exhilaration as long as the faith holds out, particularly if they are otherwise harmless. At any rate, the quack-medicine business will continue to thrive until the masses are cultivated up to a point above having faith in nostrums. The thirtieth dilution and other infinities of homœopathy can also be placed beside modern miracle cures as far as their method of operating is concerned.

THE PROPOSED NEW NATIONAL MEDICAL ASSOCIATION.

It is a pleasure as well as a duty to call attention to the suggestions of our learned and conservative contemporary the *New York Medical Journal* regarding the matter of forming a National Association of the Physicians of the United States. We have already urged the necessity and usefulness of such an organization. Our contemporary has gone further and offered a specific plan upon which to base it. This consists in forming a medical association "that shall be few in numbers and so honorable a body that membership in it would carry the highest reward that medical men here would have to hope for."

It is advised that a convention be called of eminent physicians from all parts of the country, and that this convention appoint one-half of the members of the proposed association, the remaining half to be filled up later.

The successful establishment of a society of the character indicated would certainly do much to elevate the status of medicine in the country.

The plan, however, as so far outlined, will at once strike American physicians as having this objection: It is not democratic. The association fills its own vacan-

cies and can very easily become the victim of cliques unless some further and special provisions are made. We should most decidedly advise that the several State, and perhaps certain local or special organizations, have authority to recommend physicians for membership.

Again, there is a strong disinclination among many physicians to take any step that looks like "seceding" from the American Medical Association. The proposed new association need not, however, be looked upon as at all a seceding body, but rather as an adjuvant. Its objects would be almost exclusively scientific, and its work would be in quite a different plane.

The American Association as an educational and medico-political agent may yet do something, but its organization and character make it inherently defective for securing the best scientific work; and it has of late shown such extraordinary and hopeless incapacity in dealing with certain practical questions that many of those who have been its best friends feel the necessity of a radically different organization.

We trust that the subject of establishing such an organization will be widely agitated, and that some definite and feasible plan can be drawn up.

MEDICAL STUDENTS AND THEIR PROFESSORS.

With the commencement of all metropolitan activities after the summer's rest begins anew that of medical instruction. Even in so large a city as New York, where one is almost as much lost and unobserved as if in a wilderness by himself, the medical student makes himself felt and known. There is something in his gait as he hurries from college to clinic; something in the stoop of his shoulders; a great deal in the note-books which he carries under his arm, and not a little in the expression of his eyes, which are opening for the first time on much to which the majority of mankind's are closed—that mark the disciples of Æsculapius.

While the members of the medical profession command the undoubted respect of the community, the medical student is not looked upon with that degree of approbation which the law student, art student, or the scholar in any other department of science wins for himself.

He suggests unpleasantnesses. He dissects; possibly vivisects. sickness and distress are "material" which are profitable to him. He is the one to whom the "ill wind" blows good, and is not yet empowered to make it shift into a favorable direction for others.

It is the time, too, when the professors in the Medical College arouse themselves to renewed activity. Rested by the summer's relief from lecturing they begin with zeal and vigor; as they open their lectures and call the attention of their hearers with the well-known word, "Gentlemen!" there is a crispness and freshness in it which marks the beginning of a new, though oft-repeated, enterprise. It is the old verification that "Hope springs eternal in the human breast," and the professor hopes more than ever this fall to astonish, to enlighten, to edify those who have the supreme privilege of listening to him.

We had it in mind to make a few suggestions with reference to the coming together of these two peculiar classes—students of medicine and professors of medicine—that there might result more of a mutual benefit; but the task is so difficult, one naturally hesitates, though actuated by the feeling that the present system might be improved; that better doctors might be turned out in the springtime if a somewhat different plan were pursued from that of old. The question of the *how* is not easy to settle.

There is an ever increasing tendency to make clearer compilations for students. It saves them time, but it is a questionable benefit which they derive from them. Most lectures are condensations, more or less enlivened with the experience of professors. The students, therefore, need the broadening effect of consulting "authorities" for themselves, and coming in contact with the great minds. It is possible that the students might reap a greater benefit from the methods used in ordinary school teaching rather than those which usually prevail in colleges. The recitation system is based on physiological laws. Repetition of knowledge through speech or sight secures familiarity and consequent recollection.

Professors, lecturers, and clinical instructors strive ever to find the "royal road" for their pupils in pursuit of knowledge, notwithstanding it is ever asserted with proverbial sententiousness, "There is none."

Those who hold up the banner for a higher standard of medical education in this country often become faint-hearted. A desire for patronage, a continuous rivalry batter down high aspirations in this direction. The world, however, moves, and each year sees the requirements for students somewhat in advance of the preceding. Examinations of candidates for the study of medicine would weed out many unfit to undertake it. Upon the faculties of the various colleges rest the duty and responsibility of requiring these, and that they should be more than nominal in character.

The post-graduate schools are doing an excellent work in filling up the deficiencies of graduates from the colleges. The student content with having obtained his degree, and not pressed with an extensive practice, is in a receptive frame of mind and studies the practical workings of medicine to great advantage.

Canadian Opinion on the International Medical Congress.—The new committee met in New York, September 3d, and made some concessions to public opinion, though not so many as we hoped to see. The name of Austin Flint, Sr., will be worth much among the shattered fragments that remain. Many able men in different parts of the Union will assist. We may derive what comfort we can from these considerations; but, after all, the broad, sad fact remains that the cream is principally gone, and we are left to feast on skimmed milk.—*Canadian Practitioner.*

Dr. Flint, Sr., is to be President, and N. S. Davis, General Secretary. These gentlemen are well known both at home and abroad, but many of the Presidents of Sections are scarcely known to the profession of their own country. It seems a pity that the committee had not gone a little further and removed all impediments to a complete success of the coming Congress.—*Canada Lancet.*

News of the Week.

Short-sightedness not Increasing. — There has been a great deal of rather dismal writing on the subject of the increase of myopia, especially in Germany. Dr. Emmanuel Roth, of Berlin, in a recent work on heredity, affirms that there is no such increase. He bases this view on investigations in the higher schools of Baden in 1846, and from the tests of the recruits of the district of Heidelberg. Myopia is, according to Dr. Roth, a constitutional defect, which appears about the second period of dentition.

Further Resignations from the International Medical Congress.—It is announced that Professor H. Newell Martin, of Johns Hopkins University, has declined the vice-presidency of the Section on Physiology, and that Dr. Robert Battey has resigned the presidency of the Section on Gynecology. Dr. Charles Stedman Bull, of this city, writes: "I have *long since* resigned from the council of the Ophthalmological Section of the Ninth International Medical Congress, and decline to serve in that capacity."

The Vermont State Medical Society held its seventy-second annual meeting at Montpelier, on October 15th and 16th.

The Killing of Dr. Barton.—Dr. E. Mammen, of Bloomington, Ill., writes: "This sad event did not take place in Bloomington, but at Saybrook, a town some distance east. Bloomington physicians have no reasons to slay each other. Only sweet peace and harmony prevail here."

Suspending Action as to the International Medical Congress.—We have received some very warm endorsements from active members of the American Medical Association, of our suggestion that some change be made in the present unhappy management of the Congress at the next meeting of the Association. Since, however, the Executive Committee of the Congress have issued a Declaration of Independence, little possibility of doing anything at St. Louis exists.

Dr. Nelson B. de S. Sizer, of Brooklyn, N. Y., writes: "My attention was called last night, for the first time, to a note in The Medical Record of September 12th, from Dr. Lyman, of Chicago, who refers so some statistics published by me in a recent issue of the *Lancet*, which were derived from his work on 'Anæsthetics.' I regret, with him, that there were no more recent ones available on the subject, but I am still engaged in looking up our recent literature on this very interesting topic. Dr. Lyman's name ought most certainly to have been mentioned as their compiler, but the list was taken from some manuscript notes which I made on this question some time last year, and I had entirely forgotten their origin when I wrote the letter referred to."

Foreign Advice as to the Congress.—The *Medical Times and Gazette* of September 19th says editorially: "In our opinion, the time has now come for the officers of past International Medical Congresses to meet together, and decide that, unless the pledge given at Copenhagen is kept, and all attempts to embroil the Congress in ethical disputes are unconditionally given up, the acceptance of the invitation to meet at Washington should be rescinded, and arrangements made to hold the Congress of 1887 in a country where the medical profession possesses greater solidarity."

Further English Opinion on the International Medical Congress.—The Congress Committee of the American Medical Association met on September 3d last, to "repair the damages" caused by the wholesale refusals to accept office on the part of the eminent physicians elected to this end, and the result has been so much of a makeshift, patchwork arrangement as could be accomplished under the circumstances. Meanwhile, however, resignations come merrily in, and before long the executive of the Congress will comprise an assembly of American practitioners with whose names, save for a very few exceptions, all ranks of the profession in Europe, and the majority of medical men in the States, will first make acquaintance as those of office-bearers under the patronage of the self-elected committee of management. It is thus apparent that all the good advice given to this last-named body has been uttered in vain, and that it is obstinately bent on acquiring for America the unenviable reputation of being the only country in which it has been found impossible to hold an international congress of physicians and surgeons. Such an unfortunate ending to what at the outset seemed to bear promise of eventuating in a brilliant success is greatly to be regretted; and we deeply sympathize with the disgust and chagrin that is naturally felt by the representative heads of the profession in America. The prospects of a Transatlantic Congress must now be regarded as entirely hopeless, and we presume that early steps will be taken to arrange for the 1887 meeting to take place in some country where science reigns superior to party passion and petty jealousy; and the sooner the matter is taken in hand, the better will it be for all parties.—*Medical Press and Circular*

Dr. Edwin M. Snow, Superintendent of Health of the city of Providence, has, we learn, been invited by the city officials of Montreal to take charge of the small-pox epidemic in that city. He has been tendered the absolute control of the sanitary department of the city for a period of three months.

An American Cholera Commission.—The President has issued an executive order directing Dr. E. O. Shakespeare, of Pennsylvania, to proceed, under the direction of the Secretary of State, as the representative of the United States, to Spain and other countries in Europe where cholera exists, and make investigation of the causes, progress, and proper prevention and cure of the disease, in order that a full report may be made to Congress during the next session.

The New Hospital at Gouverneur Slip is now completely built, and ready for patients. It is well built, at a cost of $14,000, and contains thirty beds. It is an emergency hospital for four precincts—the Third, Seventh, Tenth, and Thirteenth—and is a branch of Bellevue. Its visiting surgeon will be Dr. O. J. Ward; the assistant surgeon, Dr. J. D. Odell.

Small-pox in Montreal and the Attitude of the Ecclesiastical Authorities.—Mgr. Fabre, Bishop of Montreal, has, through the pastors of the various parishes in the diocese, issued a second notice, warning all Catholics that they are "absolutely prohibited" from attending religious services in any place of worship, either when they are afflicted with small-pox, or when they have it in their families, or are in any way directly exposed to the disease and liable to spread it. The Montreal *True Witness* remarks that, under the circumstances mentioned, the presence of any Catholic at church is not merely an optional matter; it is his duty and a matter of obedience to ecclesiastical authority to keep away from all assemblages of the faithful.

A Cremation Furnace Ready.—The Crematory of the U. S. Cremation Company is reported finished. Forty bodies are awaiting combustion.

Reviews and Notices.

A Reference Handbook of the Medical Sciences, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By various writers. Illustrated by chromo-lithographs and fine wood engravings. Edited by Albert H. Buck, M.D. Vol. I. Imperial octavo, pp. 808. New York: William Wood & Co.

Subscribers to this work will exhibit a great deal of curiosity in examining the first volume of the series. The general plan of the work can best be appreciated by so doing, and an estimate can be made as to what may be expected of the others. The undertaking is a huge one, requiring careful selection of subjects, systematic arrangement of them, and judicious apportionment of space to each. The accomplished and painstaking editor, Dr. Buck, has given an earnest of his endeavors in these regards which cannot be gainsaid. Messrs. Wm. Wood & Co., the enterprising publishers, have spared neither expense nor trouble in ensuring the performance of their part of the work. Typographically and artistically the volume is a model of its kind. In many respects the work differs from any heretofore published. It combines the features of a dictionary with the arrangement and elaboration of an exhaustive encyclopædia. Judging from the present volume, the field to be covered will be larger and more comprehensive than any venture of its kind, and promises the practical discussion of a greater variety of topics of interest to the general practitioner than have ever before been compressed in a given number of volumes. It is evidently the aim of the editor to give a comprehensive and condensed view of all the more important topics belonging to the broad domain of medicine. Each of the contributors has worked with those ends in view, and the reader is surprised and delighted to find how much there is in a comparatively small space which he feels he ought to know. Few, indeed, could have arranged and selected the topics with better appreciation of the means to the end. The articles have all varieties in length, but each is complete in itself as giving a bird's-eye view of the subject. Oftentimes volumes are compressed in the discussion of a single theme. Never was condensation so utilized to practical ends. From such a point of view the name, "Reference Handbook," is singularly appropriate.

The details of arrangement can hardly be described to do them justice. They must be studied to be appreciated. This can better be understood when we state that the length of topics varies from that of a few dozen lines to over seventy pages. The relative importance of each decides this matter, but there is a consistency about the whole arrangement which thoroughly harmonizes with the comprehensive design of the editor. We turn over its broad, double-columned, compactly-printed pages, each of which contains three times as much reading matter as the page of a full-sized octavo volume, and glance here and there at the make-up of the body of the work. We obtain a good idea of its true inwardness by perusing the article on abdominal tumors. Under this heading, in an admirably concise manner, are described the etiological and clinical features of abnormal growths connected in turn with the liver, stomach, kidneys, spleen, pancreas, intestine, omentum, bladder, uterus, ovaries, and miscellaneous tumors of the abdominal cavity. All this in a space of ten double-columned pages; and yet no busy practitioner who wishes to study up a case can fail to be thankful to the author for the concise, practical points which are so tersely presented. The student of materia medica seeking information regarding aconite, for instance, finds three fine illustrations respectively of the plant, root, and flower, with the therapeutics, properties, and uses of each. To the pathologist the admirable description of adenoma, with its handsome microscopical illustrations, commends itself. The surgeon will be interested in the article on amputations, comprising thirty pages with numerous illustrations, also with the different subjects discussed under the heads of aneurism, antiseptics, diseases of the rectum, anus, bladder, and breast; these varying from twelve to twenty pages in length. The physiology and pathology of the blood, occupying, with its wood engravings, over thirty pages, contains in such a space all which the general practitioner will need for reference as to literature and practical application as to his treatment of disease. The topic most exhaustively treated is that referring to the development, anatomy, histology, and pathological lesions of the brain. In the space of seventy pages we have condensed an elaborate treatise. Each of the authors of these articles has vied with the other to make the crooked paths straight and to light up the dark places. The entire area of this much-studied field is thus intelligently presented to the student. This is certainly saying a great deal, in view of the numerous futile efforts that are repeatedly made with such an object in view.

In speaking of the excellence of the five hundred and eighty-six wood-cuts, the great majority of which are original, we must not forget to refer to the beautifully-executed full-page chromo lithographic plates, four of which adorn this volume. Nothing equal to them in color and finish has been published in this country. Judging from the first volume, the success of the "Handbook" is assured. We cannot see how it can be improved. The publishers have every reason to be satisfied with their venture, and there can be no doubt that the profession at large will appreciate in a substantial manner their efforts to fulfil a promise the like of which has never before been made.

The Science and Art of Midwifery. By William Thompson Lusk, A.M., M.D., Professor of Obstetrics and Diseases of Women and Children in the Bellevue Hospital Medical College, Consulting Physician to the Maternity Hospital, etc. New Edition, revised and enlarged. 8vo, pp. 763. New York: D. Appleton & Co. 1885.

In the course of a little over three years Prof. Lusk's admirable work has advanced to a second edition. True to his purpose of keeping abreast with the times, and recording the result of advancing experience, he has not only thoroughly revised his book, but has elaborated many parts of it. Some portions have been virtually rewritten. The notable changes made are manifest in the sections on the pathology of labor and the diseases of childbed. Under the latter heading all the advanced ideas regarding the prevention and treatment of the puerperal state are presented. The author of the work has established its reputation as a leading medical authority, and in the

present edition there are abundant evidences of his ability to hold it. The style is terse and perspicuous, while the subject matter is treated from that practical standpoint which is so acceptable to the student and so interesting to the practitioner.

A Text-Book of Medical Chemistry. For Medical and Pharmaceutical Students and Practitioners. By Elias H. Bartley, M.D., Adjunct Professor of Chemistry and Lecturer on Diseases of Children in Long Island College Hospital; Chief Chemist to the Department of Health, City of Brooklyn; Chemist to the New York State Dairy Commission; Inspector New York State Board of Health; President of the American Society of Public Analysis; Member of the American Chemical Society; Member of the American Society for the Advancement of Science. With forty illustrations. Philadelphia: P. Blakiston, Son, & Co. 1885.

Of the seven primary branches of study which the aspirant for medical honors is obliged to pursue, it is safe to say that chemistry is the most neglected. The average student is accustomed to regard his attendance on chemical lectures as a bore and a waste of time, and devotes to this study only so much of his attention as is absolutely necessary to enable him to pass the required examination. This neglect is due in a measure to the belief that a thorough knowledge of chemistry is of little practical benefit to the physician, and partly also to the lack of a really suitable text-book. There are many text-books, and good ones too; but they are for the most part either too large or too small, and the student is forced either to read much that is of little value to him, or to have recourse to little manuals so condensed as to be almost unintelligible. The work before us seems, however, to have avoided both of these evils. It treats at sufficient length of all the elementary facts in physics and chemistry which are necessary for the student to know, and which have a bearing upon medicine, but has little to do with those questions which are related exclusively to chemical science. The book will undoubtedly be popular among students, and there are few practitioners who could read it without learning many facts of practical value to them in their daily work. An appendix, containing tables of the solubility and specific gravity of different chemicals, a list of incompatibles, the analysis of various animal fluids, and a glossary of unusual terms, adds not a little to the value of the book for the general practitioner.

A Text-book of Pharmacology, Therapeutics, and Materia Medica. By T. Lauder Brunton, M.D., D.Sc., F.R.S., Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; Late Examiner in the University of Edinburgh. Adapted to the United States Pharmacopœia by Francis H. Williams, M.D., Boston, Mass. Philadelphia: Lea Brothers & Co. 1885.

This work will well repay students or practitioners for the time which they may devote to its perusal and study. It is divided into six sections, treating of general pharmacology and therapeutics, general pharmacy, inorganic materia medica, organic materia medica, vegetable materia medica, and the therapeutic agents derived from the animal kingdom. A large part of the book is devoted to a discussion of the general action of drugs upon the economy, and to the methods by which this action is determined. In the sections relating to materia medica the officinal preparations of both the United States and the British Pharmacopœias are given. In addition to a very full table of contents at the beginning of the book there are three copious indexes at the end—one of bibliographical references, one of diseases and their remedies, and a general index of the subject matter. These indexes are most carefully compiled and comprehensive, and add not a little to the value of the work, enabling any one to turn at once to the desired subject without a moment's waste of time. We have no hesitation in recommending this book to the practitioner of medicine and the pharmacist as well as to the student, and feel sure that no one will be disappointed with its contents.

A Complete Pronouncing Medical Dictionary, embracing the Terminology of Medicine and Kindred Sciences, with their Signification, Etymology, and Pronunciation; with an Appendix, comprising an Explanation of the Latin Terms and Phrases occurring in Medicine, Anatomy, Pharmacy, etc., together with the Necessary Directions for writing Latin Prescriptions, etc. By Joseph Thomas, M.D., LL.D. 8vo, pp. 843. Philadelphia: J. B. Lippincott. 1885.

This work will doubtless serve the purpose for which it was intended—viz., to aid the medical student who has little, if any, knowledge of the classics, and who is consequently ignorant of the etymology and pronunciation of words of classical origin. In so far as supplying such wants the work is tolerably complete, but beyond this it cannot pretend to replace or even be abreast of the standard medical dictionaries of the day. The definitions given, although terse, are, as a rule, far from being satisfactory. In fact, there is a notable want of appreciation of the relative importance of different subjects in the space allotted them. Some of minor moment have long explanations attached to them, while others, concerning which additional information would be very desirable, are dismissed by a mere definition. There is no excuse, in a work of this sort, for occupying ten solid pages in a discussion of pathogenesis. Nor is there a good reason for devoting six pages to the cranial nerves. There is a want of system in the make-up of the work which leaves a damaging impression on one accustomed to consult dictionaries. Aside from this, it fulfils its mission in giving aid to the student of medicine or pharmacy who wishes the etymology, definition, translation, or pronunciation of any scientific term. The directions for writing Latin prescriptions are excellent, and deserve the study of every practitioner. The work is well printed.

Diseases of the Tongue. By Henry T. Butlin, F.R.C.S., Assistant Surgeon and Demonstrator of Practical Surgery and Diseases of the Larynx, St. Bartholomew's Hospital, London. 12mo, pp. 451. Philadelphia: Lea Brothers & Co. 1885.

Such compact volumes as the one before us minister to a growing taste for works upon diseases of particular organs. The author has given a concise survey of his subject, and has presented its practical points in a clear and interesting manner. The various diseases which affect the tongue are discussed from clinical, pathological, and surgical points of view, and many curious facts are related in connection with them. Some excellent chromo-lithographic representations are given showing the gross appearances of the syphilitic, tuberculous, epitheliomatous, and inflammatory lesions of the organ. Lupus of the tongue is also shown by such means.

The author discusses quite fully and impartially the different operative procedures for total and partial excisions of the organs, laying down very practical rules for given conditions of disease. He favors Baker's or Whitehead's method for simple removal of whole or part of the tongue, Regnoli's method when the front part of the floor of the mouth is involved, and Kocher's when the disease has invaded the tissues at the base of the organ. The relative mortality is presented, and the different accidents following operations are duly described. The style of the author is terse and lucid, and he gives evidence throughout the work of a practical familiarity with the entire range of his subject.

Lithocystic.—A rolling stone gathers much pus.

Reports of Societies.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, October 2, 1885.

THOMAS A. McBRIDE, M.D., PRESIDENT *pro tem.*

THE subject for discussion was

DIABETES MELLITUS,

and first with reference to *etiology*.

DR. A. B. BALL referred to two cases which had a bearing upon what was known to be the most frequent cause of the disease—namely, some mental strain or anxiety or some injury to the brain. Of course there were many cases of diabetes in which the cause could not be traced.

The first case was that of a gentleman who was a member of the board of trustees of a charitable institution in which a defalcation took place, involving the character of one of his relatives. Up to that time he had been well, and had reached fifty-five years of age. He was placed on a committee appointed to investigate the question of defalcation, and the result was that he was obliged to attend a series of meetings which consumed his time, and involved an unusual amount of mental strain and anxiety. During the second week of the investigation he noticed that he was very thirsty, and was very much depressed mentally. Dr. Ball examined the patient's urine and found that it contained a large quantity of sugar. The case ran a rapid course, and terminated fatally within six months.

The second case was that of a lady who was living separated from her husband under peculiarly distressing circumstances, and not long after the separation she began to exhibit symptoms of diabetes, which ran a course of three years, and the patient died with diabetic coma.

DR. H. F. WALKER could confirm what Dr. Ball had said concerning mental, especially moral, strain by another case, that of a lady who experienced great grief on account of the loss of a favorite daughter, and has a son sick with consumption. She has, besides, probable fatty degeneration of the heart and has an enlarged liver. But the diabetes has appeared since the mental and moral strain from grief was brought on.

Another case, having a similar cause, was that of a lady who was stricken with grief by the death of her husband, and died with diabetic coma after the disease had existed about fourteen months. During the last two years he had had almost an epidemic of diabetes among his own patients; seven cases occurring during the last year; not cases in which the patients came because they were diabetics, but developing in his own practice.

DR. BALL remarked that Seegen had directed special attention to the frequent occurrence of diabetes among the Jews, about twenty-five per cent.

DR. WALKER said that he had seen in his own practice only one Jewish patient with diabetes.

DR. C. L. DANA had a diabetic patient under his care who had been a large eater all her lifetime, and he had understood that the diabetics in India were mostly women who had been overfed. That is, one source of diabetes was in overfeeding with insufficient exercise.

DR. WALKER thought it very difficult to determine whether or not people were large eaters, as many claimed to be small eaters, when it was known that they were not.

DR. C. S. WARD asked Dr. Dana if he thought overfeeding was common in this country?

DR. DANA thought it was not common in this country.

DR. BALL believed that overfeeding of itself would not explain the occurrence of diabetes. It was well known that persons could take large quantities of starch and sugar, if otherwise in good condition, without the appearance of sugar in the urine.

DR. WALKER said that almost all the diabetics he had seen were naturally fond of articles of diet containing large quantities of starch and sugar.

DR. DANA said the point to which he referred was that persons who have diabetes from mental strain, grief, etc., are those who have been in the habit of eating largely all their lifetime.

DR. BALL thought it was not so; at all events, he knew it was not true with regard to some of his patients.

TESTS FOR SUGAR IN THE URINE.

DR. DANA said he had been using Johnson's bed-side test-papers made by Parke, Davis & Co., and they had proved very unsatisfactory. With regard to the bismuth test, it was convenient, but it had seemed to him that it was not very delicate. The test consists in rendering the urine alkaline and putting in a pinch of subnitrate of bismuth, and then boiling the mixture; if sugar was present a black precipitate was thrown down.

DR. MCBRIDE said that he had the pleasure last year of meeting Seegen, of Vienna, who impressed upon him the importance of recognizing sugar in the urine, and since that time he had seen results which had made him say with great confidence that with organic disease of the nervous system the patient would be very much improved when sugar disappeared from the urine. He had repeatedly seen specimens where by the ordinary methods of examining urine, sugar was not detected, whereas by the Seegen method it was readily recognized.

The method consists in filtering urine through *blood charcoal*, then washing the charcoal with distilled water, and examining the third and fourth washings for sugar by means of Fehling's solution. Blood charcoal retains those substances which prevent the precipitation of the copper; not only the uric acid, but the substances with which we are not entirely familiar. The first filtrate sometimes does not show the presence of sugar; but the third washing always will, if it be present.

As corroborative of Seegen's views Lauder Brunton, in an article published in the "St. Bartholomew Hospital Reports, 1880," calls attention to the fact that certain specimens of urine give a purple color with nitric acid, which give no precipitate with copper; but if more water is added, sufficient to overcome the influence of those substances which hold sugar in solution, then the precipitate with copper is obtained. That is what Seegen gets when he washes the charcoal and afterward examines the washings for sugar.

Blood charcoal is difficult to obtain, and animal charcoal *does not* give the same results; the former is essential to the detection of small quantities of sugar.

DR. BALL remarked that it would seem that Seegen ascribed great importance to very minute quantities of sugar in the urine.

DR. MCBRIDE said that he did.

DR. R. F. WEIR remarked that most English authorities said that small quantities of sugar in the urine might be disregarded.

DR. MCBRIDE said that by the ordinary methods, as Fehling's solution, etc., five per cent. of sugar might be overlooked, the sugar being held in solution by certain other substances which the urine contained. He then cited cases of nervous disorders in which marked improvement followed the disappearance of sugar from the urine: for example, a case of left hemiplegia, in which the urine contained only a moderate quantity of sugar, but in which the paralysis disappeared entirely with the disappearance of the sugar from the urine.

DR. WEIR said, *per contra*, there were many cases of nervous affections with temporary glycosuria in which the cure of the former was followed by the disappearance of the latter.

DR. MCBRIDE said certainly, but here is another observer (Seegen) who makes the opposite statement and

has thousands of cases to prove it. Dr. McBride did not wish to convey the idea that when the precautions mentioned were adopted only traces of sugar were found, as it might be present in considerable quantities, and we are yet in the dark as to what substances hold the sugar in solution.

Dr. Weir asked Dr. McBride if by using Fehling's test and detecting one-tenth sugar he had in such specimens resorted to the new German test (Seegen's) and found that it precipitated a much large quantity of sugar.

Dr. McBride replied that, not finding the one-tenth, he resorted to Seegen's method invariably; but he could not speak positively concerning an increased quantity found by the newer test.

With regard to test-papers, he had used the English papers considerably, and had found that they answered very well; but the same objection applied to them that applied to Fehling's solution.

THE MOST FREQUENT COMPLICATIONS NOTICED.

Dr. Ball reported a case which illustrated the rapidity with which diabetic coma might appear. A man was brought into St. Luke's Hospital, nearly comatose, and the history, so far as could be obtained then, was that he was a bartender, who had been up all night, and at about five o'clock in the morning he suddenly fell to the floor and became unconscious. There was no evidence of violence, nor of paralysis, and in the absence of these the question of uræmic coma arose. The bladder was found distended with urine, and forty ounces were drawn. The temperature was 97° F. in the rectum, and the pupils dilated. The breathing was peculiar, rapid, with full inspirations, and it seemed to Dr. Ball to be very much like that he had recently seen in a fatal case of diabetic coma. He directed that the urine be tested, not only for albumen, but for sugar; both were found, and the latter in very large quantity. On the following day Dr. Ball obtained from the relatives a clear history of diabetes, from which the man had been suffering for some time. The urine was tested also for acetone, but none was found, nor did the patient's breath have the characteristic odor when it is present in the urine. The case terminated fatally within thirty-six hours after admission, and at the autopsy there was the usual absence of characteristic lesions. The feature of the case especially interesting was the rapid development of the coma.

Dr. Walker said that one of his patients was a man advanced in years, who died of *fibrous phthisis* developed in the course of the diabetes; it was the only case that had terminated in phthisis.

Dr. Dana remarked that an active discussion was being carried on, in which it had been claimed that there was no such thing as the bacillus tuberculosis in the phthisis of diabetes, and consequently that it was not tuberculosis.

Dr. Ball thought it was the ordinary and generally accepted theory that the phthisis of diabetes is not tubercular phthisis.

Dr. Walker said that in his case there was a history of a pneumonic process, but there was no examination of the sputa.

DIABETES AND LOCOMOTOR ATAXIA.

Dr. Dana brought up the subject of the relation between *diabetes and locomotor ataxia*. A patient who had been treated by a competent physician for locomotor ataxia came to him supposing herself to be suffering from that disease. On examining the urine sugar was found, and there were symptoms of diabetes quite well marked; there were also symptoms of locomotor ataxia rather more strikingly marked than those of diabetes; loss of tendon reflex, a peculiar gait with a certain amount of uncertainty in the movements, pains, especially in the legs, etc., but she did not have the symptom of inability to stand with the eyes closed, there was absence of the Argyl-Robinson pupil, the pupils were natural, etc. There had been persistent insomnia, which is rather more characteristic of diabetes than of tabes. Under treatment for locomotor ataxia she was growing worse, but under diabetic treatment she had been improving.

Dr. McBride thought it was not always easy to make a differential diagnosis between diabetes and locomotor ataxia. Since reading an article, some time since, on the patellar reflex in diabetes, he had observed and found its absence and presence about equal, and had also found that it was absent in temporary glycosuria, and that it returned on the disappearance of the sugar from the urine. He then referred to a case of diabetes in which there was diplopia, absence of patellar reflex, presence of fulgurating pains, with some disturbance of equilibrium on standing with the eyes closed, a history of facial paralysis occurring some years before, etc., and he certainly, a few years ago, would have regarded the case as one of locomotor ataxia. But he had not seen a case of diabetes in which the Argyl-Robinson pupil was present, but there had always been a great improvement in the nervous symptoms with the disappearance of sugar from the urine under the use of iodoform and Clemen's solution (arsenite of bromine).

Dr. Dana further remarked that his patient also had brief attacks of aphasia, which he thought was characteristic of diabetes.

Dr. McBride had had one patient in whom there was aphasia, which disappeared within a week after the disappearance of sugar from the urine.

TREATMENT.

Dr. Ball called attention to one case which showed what a marked effect a small quantity of starchy food could produce on the urine. A lady who had been suffering from diabetes for more than a year came under his care, and at that time was practically taking a diabetic diet, with the exception of thin slices of bread daily, the whole of which weighed about *three ounces;* but she was passing about two thousand grains of sugar daily. On confining her to a strictly diabetic diet, the quantity of sugar diminished rapidly, and at the end of a week the urine contained practically no sugar, according to the usual tests.

Dr. Beverley Robinson referred to a case in which a proper diet was instituted, and after the use of various drugs during a period of six or eight months, the remedy which gave the best results was the sulphide of calcium. Clemen's solution (bromide of arsenic) had been used without any effect on the quantity of sugar in the urine.

Dr. Weir had had five cases; two rather temporary, and the other three more permanent. Dietetic treatment was introduced, according to Cantani's plan; that is, to starve the patient for twelve or twenty-four hours before beginning the diet for diabetics. This method, with sulphide of calcium, three to five grains a day, had given better results than anything which he had heretofore tried.

Dr. Ball said that in a case, now under treatment, the sulphide of calcium had proved more successful than any remedy which had been used.

Dr. Weir further remarked that in *three* of his cases he gave bromide of arsenic (Clemen's solution) without producing any appreciable benefit.

Dr. Robinson said that in St. Luke's Hospital, since 1872, there had been admitted twenty-two cases of diabetes, twenty males and two females.

Dr. Dana had used codeine with good results. He had reduced the pain and diminished the quantity of urine with the oil of gaultheria more than with any other remedy. He thought that Clemen's solution was no more effective than Fowler's solution, and that it was substantially the same preparation of arsenic.

Dr. McBride had been very much pleased with the effects produced by Clemen's solution and iodoform. If

Clemen's solution was the same thing as Fowler's solution, it was much stronger. Iodoform, in three- or four-grain doses, had acted very favorably.

Within the last year he had seen several cases which were interesting because there were certain starchy articles that could be taken without doing harm; for example, potatoes and corn-cakes; and a case had been mentioned to him by Dr. W. M. Carpenter in which the patient could eat buckwheat cakes without producing sugar in the urine.

The best bread for diabetics which he had seen was that made by G. B. Hecker of Cherry Street, who became interested in the preparation of the bread, because of a son who had diabetes.

Dr. Walker had had one diabetic patient who could take buckwheat cakes with impunity.

Dr. Robinson referred to a case in which the patient was obliged to use the glasses for reading which he formerly wore when walking in the streets. There was a large quantity of sugar in his urine, and an oculist had told the patient that the necessity for changing his glasses was due to lessening of the intra-ocular tension.

Dr. Weir mentioned a life insurance company in which it was the custom to accept applicants whose urine contained only a very small quantity of sugar, because experience had shown that the longevity of the persons was as great as that of other people.

The Society then went into executive session.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

MESMERISM—A MESMERIC DISPLAY AT MANCHESTER—THE NEW GUIDE TO THE NEW PHARMACOPŒIA—THE LATE JOHN GAY, F.R.C.S. ENGLAND—THE LATE FRANCIS HARRIS, M.B. CANTAB.—MORE DEATHS IN THE PROFESSION — THE LATE DR. M'DOWELL—MR. HENRIQUES —MR. EDWIN CANTON—MR. T. S. WALKER—THE INTRODUCTORIES AT THE LONDON HOSPITALS FOR THE NEW SESSION—VIEWS OF MR. COWELL, DR. FOWLER, PROFESSOR SCHÄFER, MR. PEPPER, AND MR. HOLMES.

London, September 29, 1885.

There is nothing new in mesmerism, and yet it retains the power to set up violent assertion and contradiction. At Manchester a certain professor, of whom, as he hails from your side of the water, we must speak with respect, has been giving a sort of exhibition which has provoked much remark. By some kind of interest the professor secured the use of a hall in Owens College, and great is the outcry against the rulers of that institution for thus sanctioning the pretensions of this pseudo-science.

A certain class of mind is naturally excited by the wonders which are easily produced. Others resent what they regard as an attempt to impose on their commonsense and to take advantage of their easily deceived fellow-creatures. Doctors familiar with the strange truths and falsehoods of hysteria are not very tolerant of the pretensions of mesmerism, electro-biology, *et hoc genus omne*. I remember very well some years ago a lecturer giving a number of rather striking illustrations, in a provincial public hall, of the wonderful power he possessed over some of those present, compelling them to assume attitudes and perform antics which kept the rest of the audience in roars of laughter. A doctor in the town, with whom I was staying, went to the lecture, and at the conclusion proposed to give those who liked to stay an explanation. He entered fairly into it, and when the people seemed a little doubtful told them he could do the same things himself, and although, as he told me, he had never before seen the things done. Do them he did, and with great success, and as he and all the persons operated on were well known in the town, there was no collusion in the matter. He then asked the lecturer to operate on him, but I need not say he was not a good subject, and the electro-biologist could not control any of his actions.

There is in London a small building called the Mesmeric Hospital, and perhaps the American gentleman may get the use of that, now he has stormed the scientific castle of Owens College, where it seems the *medical* students were not so impressible as the rest of the audience.

In a previous letter I gave you some account of the new British Pharmacopœia (which appeared on the 2d of this month), so far as a first examination permitted. Of course it is the subject of common conversation; it being so long since the work was revised. I have now to announce that already one of the London teachers of materia medica has brought out a little volume to assist practitioners and students in digesting the new authoritative standard. I have before me a copy of this little book, entitled "A Guide to the New Pharmacopœia," by Prosser James, M.D., Lecturer on Materia Medica and Therapeutics at the London Hospital. It is a neat little book of over one hundred pages crown 8vo, and gives an epitome of all the changes, then a full account of all the new drugs admitted, their characters, uses, dose, and modes of administration, with a very full therapeutical commentary. The author aims to make it a supplement to the Pharmacopœia, as well as to manuals of materia medica. It is so full that really if bound up with the old Pharmacopœia it would save buying the new.

So it brings down to date, so to say, all the text-books of the materia medica. In these last many of the new drugs are, of course, treated, though more briefly than others, and the words "non-officinal" are generally prefixed. This serves to tell students to pass them by, and the result has been they were little studied. Dr. James' "Guide" can therefore be referred to in the margins in reference to these and also a mark should be put showing where to find other drugs, and thus an old copy of a text-book brought down to date and again made useful. Of course this will not last, as new editions will come out (a new edition of Dr. Whitla's little manual is announced as nearly ready) and new students will buy them; but in the meantime many will be thankful to get for half-a-crown all they need for the present in this little "Guide," which seems very complete, for I have found in it reference to mere trifling changes, showing how minutely it must have been examined.

In my brief summary in a previous letter I ventured to criticise some of the changes made, especially in regard to the strength of active remedies. It is gratifying to find this professor of the subject has similar opinions, and has put in the forefront of his "Guide" a signal as to changes which may be dangerous. He also interspersses the details of chemistry, botany, pharmacy, and so on, not only with a therapeutical commentary, which I suppose must be accepted as authoritative, but with bits of information and, *horribile dictu*, with criticisms on the conscript fathers of the medical council and their new Pharmacopœia which make it lively reading, so far as I have gone. The book only appeared yesterday, but I have read enough to predict it will create some talk, and here and there some of the sarcasms will not be relished.

Many of your readers will remember the name of John Gay with respect, and be familiar with his contributions to surgery. He died on the 15th inst., full of years, and the honor and respect of all who knew him, as a man of high principle, who had worked steadily and well in his profession, and achieved the distinction due to ability conjoined with industry. Your younger readers may imagine from the work he put into his Lettsomian lectures (1867), on varicose disease of the lower extremities, that he was still in his prime, but he was then getting on in life, having been born in 1813. So much the more creditable to be engaged in numerous dissections in order to give his lectures greater value. His last contribution was on hæmorrhoids, and meeting him about that time

I was forcibly struck with the degree to which he had aged since I saw him some years previously.

However, we spent a very pleasant evening together, and I found his mind as active as ever. Some time after, about two years ago, the cloud gathered—cerebral mischief occurred, paralytic symptoms appeared, and, with slow but steady progress, the end came.

Another notable death may be named, Dr. Francis Harris, who was Consulting Physican to St. Bartholomew's Hospital. He was only fifty-five years of age at his death. He had retired early from the active staff of "Bart's," as he had means sufficient without practice—but he had worked so well for his hospital that he was made "Consultant." He was a Cambridge graduate.

London, October 1, 1885.

My last letter concluded with a reference to some recent deaths. Others remind us how the enemy is always among us. Though not a Londoner, Dr. B. G. McDowell was not unknown to some of us. I had had various communications with him. He had achieved such distinction in Dublin that on the death of Dr. Hudson, four years ago, he was made Physician to the Queen in Ireland, to the satisfaction of all his brethren. He was a man of great ability and wide learning. He exemplified the possibility to some men of doing more than one thing well. He had been a hospital surgeon, then became a hospital physician, professor of anatomy, and eventually examiner in medicine. He contributed valuable papers to Todd's "Cyclopædia of Anatomy and Physiology," to the *Medical Press and Circular*, etc. He died on September 15th, after a few days' illness, at the age of sixty-five.

The late Mr. Henriques, who died on September 8th, in the ninetieth year of his age, was a somewhat remarkable figure. He had long retired, but had practised successfully in Jamaica from 1820 to 1825. He underwent lithotrity at seventy-five and enjoyed his after-life. He was the real hero of the story told by Sir A. Cooper of one of his pupils, a lad who came to study from the West Indies, and on his return had the skill and courage to operate on his father for double cataract. Success attended the venture, and the plucky young surgeon had the joy of restoring his parent's sight.

Contrasted with some of the peaceful deaths I have lately reported, how sad is the story of the close of Mr. Canton's life! He was found dead on one of the seats on Hampstead Heath, a bottle lying beside him which had contained prussic acid. He was Consulting Surgeon to Charing Cross Hospital, at which institution he had worked for many years, during which he added to medical literature some valuable contributions. Of these your readers may probably have remembered his book on arcus senilis. I well remember meeting him after its publication, and talking over that and other medical topics, little dreaming that the active mind to which I was then introduced would succumb to the cares of life in so sad a way. He was a popular teacher in his school, and his lessons in surgery and surgical anatomy were well exemplified in his care of patients and his dexterity and skill as an operator. With the most exact knowledge of the anatomy of the part, amounting to an ability to keep before his mental vision a perfect picture in every detail, his confidence never failed. Still he was never reckless—no precaution was ever omitted, and every operation was performed carefully, although with the dexterity of the most accomplished expert. There are young surgeons in London to-day who would do well to imitate Edwin Canton, rather than seek reputation as operators by risks which patients would not run if they were able to judge. Mr. Canton published some valuable illustrations of surgery and pathology, of which those on "rheumatic arthritis" will be specially remembered. He collected and carefully examined many specimens, which he afterward presented to the museum of his hospital and to the College of Surgeons. His literary abilities were also enlisted by non-medical papers, and among others he contributed to *Punch*. Active, zealous, witty, his company was very pleasant, and many will regret that his mind, which had for some time become clouded, should have been so completely unbalanced at last. He had retired from work for six or seven years, and at his decease was in his sixty-eighth year.

Mr. Whitefoord, M.R.C.S., formerly practising at Hammersmith, lately died by his own hand. He had the misfortune to contract blood-poisoning about four years ago, and had suffered much ever since. His mind at length gave way, and going into his consulting-room on the 25th he cut his throat and tried to jump out of the window.

To these sad fatalities may be added one or two reported in the papers as occurring abroad from overdoses of morphia, taken apparently medicinally, by members of the profession.

From Liverpool comes the news of the decease of Mr. Thomas Shadford Walker, who had achieved a position in ophthalmology which will have made his name known to your readers. He was Lecturer in the Medical School, and Surgeon to the Special Hospital in Liverpool. His contributions to the "Medical and Surgical Reports" of the same place were noteworthy, and had received extensive consideration among specialists.

October 2d.

October 1st—the great opening-day of all the English medical schools—has just passed, and the introductory lectures are to-day the one topic of medical gossip. Yesterday there was no address at St. Bartholomew's, which has for some time discontinued the custom, nor at one or two schools which have followed its lead. The London Hospital, now the largest in the kingdom, had also no opening ceremony, the college being in the course of enlargement. At the Westminster the new school buildings were opened, and the introductory lecture duly delivered by Cowell, who gave a short history of the four buildings in which the teaching has been carried on since 1834. He then said a word in favor of lectures, the value of small schools and demonstrations, and passed on to topics of more general interest—the restraint of lunatics, and the need for a real university in this great city. He objected to "watering down" the degrees of the so-called University of London, and would prefer the setting up of one or two new universities to do the work so urgently needed. It is strange how screwing up the standard, so as to compel men to cram for a degree, should blind even practical men to the injury thus inflicted on professional education. The time young men waste in getting up the minutiæ of theory—pure book-work—when they ought to be in the wards of the hospital, may give them success at an examination, but cannot make them either physicians or surgeons.

At the Middlesex Hospital the same subject was touched by Dr. K. Fowler, who though he said the present rage for titles was an evil, held it to be a much greater misfortune that for the sake of getting a degree a student should go to a school where clinical teaching hardly existed and where he had no chance of obtaining resident appointments, and he expressed his hope that the various schemes now before the professional world would result in the institution of a London degree which shall maintain in the purely professional subjects the high standard of the older universities, and for which the other requirements shall not be beyond the reach of men who are fully worthy of the distinction. Dr. Fowler fully recognizes that the relative value of all honors is only to be understood by the initiated, and so long as the mere accident of a man studying in London virtually deprives him of distinctions attainable on easy terms in Ireland or Scotland, the London schools must suffer from the injustice they have so long patiently endured. Dr. Fowler also dealt with the dangers of the present state of our lunacy laws.

At University College Professor E. A. Schäfer, F.R.S., delivered himself of his views on medical education, of

course putting his own subject first, after the manner of the majority. It must be confessed in some things he had much on his side, and it was refreshing to hear him say he should be sorry to confess how little he retained of the dry bones of anatomy with which he had been stuffed before he became a teacher of physiology. Then he fell foul of materia medica—probably as the subject too often abused, or as the one, if eliminated, which would make room for more time for physiology. He forgot, however, that the London teachers of materia medica have largely effected the reform, inasmuch as they have devoted their lectures to therapeutics rather than to botanical or chemical details; and this with the cognizance, and therefore the sufferance, of the examining boards. Mr. Schäfer sketched an excellent course of training, and one which industrious and wealthy men would do well to follow, but one, it is to be feared, quite impracticable. Students as a rule are not rich, if industrious, and they do not want to become investigators in the region of physiological research. They have a limited time in which to become practitioners, not scientists; doctors, not physiologists. It is the forgetfulness of this by examiners which is so much to be deprecated. It may be of vital interest to Mr. Schäfer to know that in the laboratory of Hinab a research was made which is in direct contradiction to the results obtained at Hinauf; but every general practitioners knows that he can afford to wait until the gentlemen of Hinauf are reconciled to those of Hinab, or until some quiet British experimenter, unendowed and unrewarded alike, shall show that neither Hinab nor Hinauf is to be trusted, as both are wrong.

Still every one must feel that Mr. Schäfer has right on his side when he protests against London being unable to get a shilling from the treasury for the endowment of science, while Ireland can get new universities and colleges, Scotland building grants and endowed professorships, and even little Wales a moderate subsidy.

The reason is obvious. Scotland would make it unpleasant to a minister who refused; Ireland has long taken the bribes offered and asked for more; the request of Wales is so very modest, still it is unanimously supported. But England, especially London, has no cohesion. Now and then a lecture like Mr. Schäfer's is delivered, but there is no union among the teachers, no possibility of approaching a ministry in a way to command attention, if not compliance; so statesmen of either party can afford to ignore the demands of doctors or scientists alike.

Mr. Schäfer sees this, and closed his lecture with a demand for unanimity in pressing on Government the duty of making a provision for medical education in London second to that of no city in the world.

At St. Mary's Hospital Mr. Augustus J. Pepper delivered the lecture, and he, too, dilated on education and degrees, his opinions serving to show how impossible it seems to be to attain the unanimity which Professor Schäfer demanded.

Mr. Pepper is a distinguished graduate of the London University, and he has a horror of any proposal to make its degrees more easily attainable. He says that he would "rather it ceased, and be henceforth only a name and an influence." He is willing to see a new teaching university, but not if that be made subservient to the design of rivalling Scotch universities. Mr. Pepper is a young teacher, he already sees some of the difficulties of the London student, and is half conscious of the injustice under which he labors.

But Mr. Pepper mistakes the position. He is not correctly informed as to the object of his university's foundation "by royal charter," and he talks of "the sacrifice to one of the most despicable traits of human character" in a manner to suggest he has not grasped the "exigencies of the situation." What are these "despicable traits?" Simply the demand for justice on behalf of London—that London students shall have the same distinctions open to them as their Scotch and Irish fellows, and that his university shall either do its duty or stand aside, and be nothing but a name. Mr. Pepper is one of those men who would always succeed at an examining board, and he cannot, apparently, see the difference between a passman and a prizeman. With "all his blushing honors thick upon him," it is almost shocking to hear him cry out lest others should get a degree more easily than he has done. He has become an examiner. What will happen if he is suffered to carry out such views, and keep up the pass standard to that of honors? Mr. Pepper then commended general literature to the attention of students. This is the more to be commended, since some people have whispered that he could not have paid much attention to this, or he would never have had time to gather so many medals. Readers of his otherwise excellent "Manual of Pathology" have expressed to me their chagrin that its style was so defective.

At St. George's Hospital, Mr. Timothy Holmes, whose "Manual" and "System of Surgery" are so well known, was the lecturer, and he passed in review the colleges, schools, and hospitals. He admitted the defects of the two royal colleges, but seemed to anticipate that the project for amalgamation might result in a remedy, and that if invigorated by a more popular organization, the influence of a body such as would be produced would be paramount, and we might then look for the redress of many abuses which are now felt in our daily life. The misgiving most will have as to this prospect arises from the doubt whether corporative selfishness can be exorcised from these ancient but corrupt bodies.

OUR CANADA LETTER.

(From our Special Correspondent.)

AN INTERESTING MEETING—PERSONAL ITEMS—NEW HOSPITAL FOR WOMEN—DEATH OF A VETERAN—SMALL-POX IN MONTREAL—A NEW THEORY—OPENING OF CANADIAN SCHOOLS OF MEDICINE.

THE recent meeting of the Canada Medical Association at Chatam is spoken of as one of the most pleasant gatherings since the formation of the Association. The welcome presence of several American visitors, and the interest they manifested in the different discussions in the several sections, gave rather an international character to the assembly.

Dr. Hingston, of Montreal, has the honor of being the first surgeon in Canada to remove the kidney for cystic disease of that organ. The patient, a young lady, made an excellent recovery.

Dr. Charles O'Reilly, the genial Medical Superintendent of Toronto Hospital, has just returned from Europe, where he has been making a tour of inspection through the large hospitals of the continent.

Dr. William Osler, of Philadelphia, formerly of McGill College, Montreal, has been selected to deliver the next course of the Cartwright lectures. Dr. Osler is a Canadian sojourner in the United States, and has many warm admirers in the Dominion, where he is largely known.

The Sisterhood of St. John the Divine, of the Church of England, have opened in the city of Toronto a hospital for women. Although this institution cannot claim great dimensions at present, a grand and useful career is predicted for it. The rules governing the hospital are simple and can without difficulty be complied with. Unlike many other such institutions, the surroundings do not savor of that red-tapery which too often lessens the usefulness of such enterprises.

The death of Dr. John Mackieson, of Charlottetown, P. E. I., is announced. He had been in practice for over seventy years and was the oldest practitioner in Canada. The positions he held during his lifetime indicate the high esteem in which he was held by his fellow-citizens.

The prevalence of small-pox in Montreal has awakened

the local boards of health in every section of the Dominion to somewhat increased diligence. The organization of local boards of health is much more advanced in Ontario than in any of the other provinces. Already there are between two and three hundred boards organized. Each municipality in Ontario is required by an act passed at the last session of the Legislature to organize a local board of health, and there are six hundred separate municipalities in the province. A medical health officer is generally associated with each Board. The Public Health Act of Ontario may well be copied by the other provinces in Canada. There are at present over eight hundred cases of small-pox in Montreal.

Dr. Buck, of London, Ont., has enunciated the fact that if a patient be not thoroughly under the influence of chloroform, any irritation of the fifth nerve will produce slowing of the heart and final stoppage through the pneumogastric nerve.

The Canadian medical schools are again resuming their work, and as usual the attendance is said to be largely in excess of that of any previous session. The buildings of the Toronto School of Medicine and Trinity School of Medicine have been greatly improved during the vacation, and the museums of each have been made much more attractive. McGill College, Montreal, which enjoys a large endowment, has been much enlarged, and is now said to be better equipped than at any previous time in its illustrious history. The faculty of the Royal College, Kingston, has been greatly strengthened by the addition of new material, although the past few years have witnessed the removal from the teaching staff there of some most excellent men—notably, Dr. M. Lavell, one of the oldest and most esteemed teachers in the province, and who has acquired more than a local fame as a practical gynecologist. He has retired to accept the position of warden of the Provincial Penitentiary, an office to which he will bring the best of qualifications. The Royal College has secured the services of Dr. William H. Henderson as Lecturer on Physiology. This gentleman has devoted a great deal of time and study to his specialty both at home and in Europe, and although a comparatively young man has secured considerable distinction as the reward of his industry. Dr. Sullivan, who has filled the chair in Surgery for many years at Kingston, has been called to the Canadian Senate, in the halls of which legislative body he will in future give vent to the same fervid eloquence that characterized him as a lecturer. No changes of any importance have been made in the faculties of the other Canadian schools.

How Brain-workers should Live.—A letter, written by Mr. Edward Everett Hale, is published in the *Herald of Health*, in which the writer relates the mode of life which he has found by experience to be most conducive to health while engaged in literary work. The letter contains some very practical points, especially upon the necessity of sleep, which are so apt to be ignored. He has found that, in order to procure sleep, the brain must not be excited or worked hard for at least six hours before bedtime, and consequently the greater part of the work must be done in the morning or early afternoon, and none at all in the evening. The latter period is to be spent in light reading or other form of recreation. Another point which the writer has learned well from experience is the necessity of good substantial food and plenty of it. Food and sleep are absolutely necessary for everyone, and above all for those who work with their brains. It is seldom hard work that kills, but irregular work, and work performed at the wrong time. Young men who perform their most severe literary labor in the evening, and there are many of them, are men who are abusing their powers, and who, in nine cases out of ten, will live to regret their imprudence, if they live at all.

New Instruments.

A NEW POST-NASAL CUTTING FORCEPS.

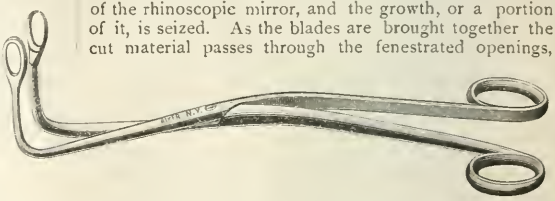
With Illustrative Case of Adenoid Tumor.

By H. HOLBROOK CURTIS, M.D.,

NEW YORK.

Several cases have presented themselves to me in which I found large adenoid growths invading the pharyngeal vault, about which it was difficult to adjust the wire of Jarvis' snare or the thermo-cautery, and for the removal of which no satisfactory cutting forceps have as yet been presented. I append the cut and description of a new instrument, which, in my hands, has proved very satisfactory, and which promises to do away with the difficulties which now present themselves, especially in those cases where the growth is flat and has no constriction at the base, or so large that the greater portion of the pharyngeal vault is occupied.

The forceps are made on the principle of a Thomas' double uterine curette, the sharp edges continuing all around the opening, the blades approximating as the instrument is closed. The forceps are introduced by aid of the rhinoscopic mirror, and the growth, or a portion of it, is seized. As the blades are brought together the cut material passes through the fenestrated openings,



which enables the operator to incorporate a much greater portion of the growth at one cutting than when the ordinary cup forceps are employed. I have had the forceps manufactured at angles of seventy, ninety, and one hundred and twenty degrees for greater convenience in operating, though the seventy degrees forceps are all that is absolutely required. These forceps will remove, piece by piece, with great ease, any adenoid growth in the pharyngeal vault with but the slightest amount of discomfort to the patient. Below is reported a description of the case for which the forceps were devised as being one of special interest.

Miss R——, Brooklyn, came to me on May 1st with history as follows: Patient had been unable to blow her nose for several years; was of necessity a mouth-breather; was growing deaf; eyes were very weak; had difficulty in breathing on slight exercise or going up-stairs; suffered from general malaise; was anæmic; digestion good; face had the characteristic, anxious look, and the contracted upper lip of a patient suffering from nasal stenosis; complexion eczematous; a watery discharge from the nose was constantly troublesome. Examination of the nostrils revealed much hypertrophic stenosis. The pharynx was congested. On saying Ah, the lower border of a pharyngeal growth appeared on either side of the uvula. Rhinoscope examination showed the entire pharyngeal vault to be occluded by a tumor attached to the basilar process, pale in color and very solid in consistency, as determined by palpation. The tumor was so large that it was impossible to pass a wire loop over it through the pharynx, as the anterior portion appeared to intrude upon the mares. The growth had pushed forward the soft palate, leaving abundant space behind the uvula for manipulation. Having procured the forceps made on the pattern of the cut inserted above, and after applying a six per cent. solution of muriate of cocaine, I attacked the growth with the forceps, each time removing pieces as large as a good-sized pea, until I had taken out six or seven such. The pain occasioned was not excessive, but I was obliged to delay operating on account of the hemorrhage, which, however, was slight and

readily controlled by means of a pledget of cotton and a simple astringent. My patient returned every third day, and in thirteen sittings the tumor was entirely removed. I sent pieces of the growth to Dr. Stowell, who reported it a simple adenoma. By means of the forceps I was enabled to trim with great nicety the pharyngeal vault in a more satisfactory manner than I have ever succeeded in doing with the snare. The removal of the nasal hypertrophy and Eustachian catarrh next occupied my attention. This was effected by thermo-cautery and chromic acid applications to the swollen tissues over the inferior turbinated bones, keeping the parts well cleansed and inflating the Eustachian tubes with the vapor of iodine and ether. The patient reported to me on the 20th of August. She was breathing through her nose; had increased much in flesh; was strong, healthy, and in good spirits, being most grateful for the benefit she had received. I consider this mode of extirpation the very best. Firstly, one is conveniently able to remove a small piece of the tumor from a difficult location and examine it for purposes of diagnosis. Disagreeable hemorrhage is prevented. The difficulty of adjusting the thermo-cautery wire or snare loop is overcome; and secondly, the idea of an operation, which in itself is ofttimes horrible to the patient, is done away with. The average person will be much more content to have a few pieces removed at a time than submit to an operation, with its necessary preparations, just as many persons insist on the frequent application of chromic acid to the tonsils instead of allowing amputation.

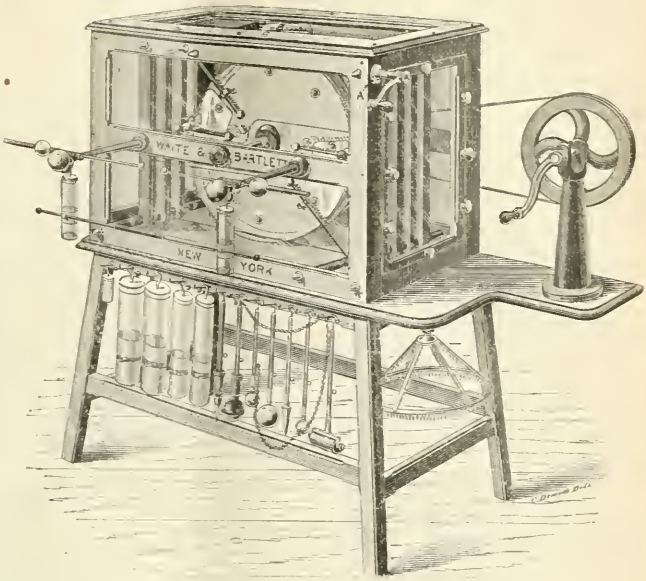
A NEW APPARATUS FOR GENERATING STATIC ELECTRICITY.

By AMBROSE L. RANNEY, M.D.,

New York.

I would call the attention of the profession to an improved static machine which has been lately devised by me.

It is the result of many months of experimentation, and is the outgrowth of the dissatisfaction which all other devices for generating electricity by friction have afforded myself, as well as others who have employed them. By those who have had experience with static machines it is generally conceded that they are frequently charged with difficulty and give but a feeble spark during damp weather; and that they are particularly unsatisfactory and of little service during the summer months, when such conditions are liable to prevail. It is also conceded that some form of motor is generally required to run a machine of large size, because the hand is soon fatigued in overcoming the friction of the plates upon the rubbers in addition to that produced by the bearings of the axle, and the belt which connects the driving-wheel with the axle. Furthermore, it is now well recognized that plates of large size (16 to 24 inches in diameter) and several of them are absolutely essential to a machine which is intended for medical use. Small single-plate machines do not give sufficient quantity or length of spark to be of any practical benefit as a curative agent. Again, it has been found by experience that building a glass case over a static machine does not thoroughly protect the plates of the instrument from dampness. No cabinetmaker can make joints of wood which will not admit of much moisture when the outside air is impregnated with it; and chloride of calcium, if placed within the case, will not absorb all the dampness



that enters and collects upon the plates and metal of the machine.

For a long time, I was in the habit of burning an alcohol lamp of large size within the case of my own machine during damp weather to obviate this serious objection; but to insert and withdraw the lamp the doors of the case had to be opened, and the plates were thus unduly exposed to moisture.

In the second place, I found by experience that all the electrodes of a static machine (being insulated by glass) were liable to be easily broken; and that the poles of the instrument, when by accident exposed to outside violence or a blow, were also liable to cause a breakage of the glass windows in the case of the machine which they perforate in most of the later models.

In some machines, the case is moreover too small for the plates and allows of an escape of more or less of the electricity generated. The first machine which I made upon the present plan had this objection. It would give the operator an occasional shock in consequence of this defect when the hand was used as a motor, and it lost a large percentage of the volume of electricity generated by "grounding" that proportion which jumped to the metal parts of the case.

Without entering further into numerous difficulties which I have had to encounter and overcome, I may summarize the more important improvements made in the machine shown here in the accompaning cut, as follows:

1. The case is so constructed that all of its joints are packed with soft rubber before its screws are tightened. This prevents the entrance of moisture from without and makes the machine a useful one at all seasons of the year.

Soft rubber now constitutes the best packing for steam apparatus, and is also used in hermetically sealing fruit-jars in preference to any known material. All imperfections in the joints of the case are perfectly sealed in this instrument.

The *doors of the case* are so arranged as to be drawn tightly in contact with a frame covered with soft rubber by means of milled screws.

The glass in the case is put into the frames with putty, which is impervious to air.

The poles of the machine perforate the wooden portion of the case instead of the glass windows. They are insulated with hard rubber and the apertures are protected by soft rubber packing placed between hard rubber buttons and the wood. Thus the danger of breakage of the case by accident is decreased without impairing its impermeability to dampness or allowing of leakage of the electricity generated when the machine is in use, while the strength of the case is materially increased by this modification.

2. The axle is so built as to reduce the friction to a minimum and to allow of its being oiled without opening the case.

3. The driving-wheel is very large and rests upon a cast-iron support. This insures both ease of motion and durability.

4. The glass plates of the machine are nine in number. Six of these revolve and three are stationary. The stationary plates are of peculiar shape. The revolving wheels are made of carefully selected glass, so as to be as true as possible and bear evenly upon the rubbers as they revolve.

5. The excitants consist of cat-skin rubbers between the inner plates and metal buttons upon the outer plates, which touch as they revolve upon fixed metal brushes.

6. The collectors have tinsel attachments which aid in gathering the electricity generated.

7. The electrodes are made with handles composed of hard rubber instead of glass. They are therefore less liable to be broken and are as perfectly insulated.

8. Each machine is provided with three pairs of Leyden jars of different sizes. It is arranged also with hooks upon which the electrodes may be hung when not in use.

In conclusion I would say that I have produced with the machine here described, and now in my office (24-inch plates), a spark of eleven inches in length during a muggy day in August, when most static machines would fail to charge. It runs, after a few turns by the hand, for nearly a minute without any power and generates without interruption. Any boy of seven years of age can run it without fatigue for half an hour.

Respecting the uses of static electricity in medicine I would refer the reader to my lectures, lately published in the *New York Medical Journal*.

The machine here described is manufactured by Waite & Bartlett,[1] of this city, who have been industriously occupied for several months in perfecting it under my guidance.

The cost of this machine has been materially reduced from the schedule prices of other makers for similar instruments, rather than increased by the improvements made.

156 Madison Avenue, September 1, 1885.

Number of Physicians in Sweden—Proportion to the Population.—The official report for 1883 gives 445 as the number of physicians, of whom 137 were "province" or county physicians. Further calculation gives for the country at large 1 physician for 7,909 inhabitants. Stockholm, with 122 doctors, has 1 for every 1,594. In some of the larger and sparsely inhabited provinces the disproportion is astounding; thus, Norbotten has 1 to 10,415; Vesterbotten, 1 to 12,262; and Elfsborg, 1 to 16,654!—(From the Swedish newspaper, *Nordstjernan*, published in New York.) The apothecaries shops for the whole country number 1 to 18,924 persons; in Stockholm, 1 to 12,964; in the province of Christianstad, 1 to 28,418!

Weisel, Daniel, Captain and Assistant Surgeon. To be relieved from duty at Camp at Rock Springs, Wyo. and return to his proper station, Fort Fred Steele, Wyo. S. O. 99, Department of the Platte, October 1, 1885.

Adair, George W., Captain and Assistant Surgeon. Leave of absence extended one month. S. O. 232, A. G. O., October 9, 1885.

Biart, Victor, Captain and Assistant Surgeon. Sick leave of absence further extended six months on surgeon's certificate of disability. S. O. 227, A. G. O., October 3, 1885.

Bushnell, G. E., First Lieutenant and Assistant Surgeon. Granted leave of absence for one month. S. O. 215, Department of the East, October 6, 1885.

Stephenson, William, First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Niobrara, Neb., and ordered for duty at Camp at Rock Springs, Wyo. S. O. 99, Department of the Platte, October 1, 1885.

Chapin, A. R., First Lieutenant and Assistant Surgeon. Leave of absence extended one month. S. O. 230, A. G. O., October 7, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending October 10, 1885.

Bright, George A., Surgeon. To United States ship Brooklyn.

Fitts, Henry B., Assistant Surgeon. To Naval Hospital, New York.

Hall, John H., Passed Assistant Surgeon. Detached from Naval Hospital, Mare Island, Cal., and ordered to the Hartford.

Swan, Robert, Passed Assistant Surgeon. Detached from Naval Hospital, New York, and ordered to the Brooklyn.

Medical Items.

Bromine as a Disinfectant and Insecticide.—It is said that a bottle of bromine left in a closed room all night with the stopper out destroys all infection and insect life. It is far more effectual than the vapor of burning sulphur.

Tapeworm in a Young Infant.—At a recent meeting of the District Medical Society for the County of Hudson, N. J., Dr. S. A. Helfer, of Hoboken, exhibited portions of a tapeworm, in all about five feet in length, removed from a nursing infant five months old.

Eucalyptus Oil in Bronchitis.—Professor H. C. Wood says that the oil of eucalyptus in ten-minim doses (in gelatin capsules) four times daily, has, in his hands, replaced all stimulant expectorants in chronic or obstinate subacute bronchitis.

The Homœopathic Remedy for Diabetes.—Extract of sweet pea.

Another Vacation Chestnut.—One of the most prominent physicians of Indianapolis, on his return from a summer vacation of three weeks, was met by the leading undertaker, who said: "Ah, doctor, so glad to see you safe back; we have missed you so much."—*Atlanta Medical and Surgical Journal.*

The Pulp of the Cimmaroma, a plant found both in the Brazils and in Spain, is said to be valuable as a laxative, ten grains of the alcoholic extract being sufficient to produce an action of the bowels. Mixed with vinegar and water, it is used by the natives of Brazil for erysipelas.

Original Lectures.

LECTURE ON BACTERIOLOGY.

DELIVERED IN THE MEDICAL DEPARTMENT OF THE CITY OF NEW YORK, OCTOBER 14, 1885.

BY ALFRED L. LOOMIS, M.D., LL.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, NEW YORK.

GENTLEMEN: Before commencing the history of the so-called infectious diseases, I will invite your attention to a brief consideration of those low forms of life which have become known to our every-day literature as Bacteria. The scientific world is at present devoted to their study, and it is a subject of especial importance to us in commencing our studies of the etiology of the class of diseases which are about to engage our attention.

If bacteria are active elements in the production of pathological conditions, their biology becomes a matter which must concern every progressive medical investigator. If, on the other hand, as many are inclined to believe, they have little or nothing to do with the causation of disease, it equally becomes us as intelligent men to investigate, and if possible determine their real significance. At different periods in the history of medicine different theories have been advanced, and for a time have held the minds of the profession, to account for the causation of disease, as well as for the peculiar phases which it assumes during its active progress.

There are at present two prominent theories in regard to the infections which produce disease. The first is based upon chemical processes; the second upon the multiplication of living organisms. The chemical theory maintains that after the infectious element has been received into the body it acts as a ferment, and gives rise to certain morbid processes, upon the principle of catalysis. The theory of organisms, or the germ theory, maintains that the infectious elements are living organisms, which, being received into the system, are reproduced indefinitely, and excite morbid processes which are characteristic of certain types of disease. This latter theory so readily explains many of the facts connected with the development and reproduction of infectious diseases that it has been unqualifiedly adopted by a large number of investigators. The proofs of this theory had not, however, advanced beyond the demonstration of the presence of certain forms of bacteria in the pathological changes of a very limited number of infectious diseases, until February, 1882, when Koch announced his discovery of the tubercle bacillus, since which time nearly every disease has its supposed microbe, and the race is indeed swift in which the would-be Kochs press forward with new germs for public favor.

It is my purpose this afternoon to pass in rapid review the subject of Bacteriology, noting first the different genera, their biology, etc., and the modern means employed in their study. In referring to the practical study of our subject, I shall do little more than describe very briefly the processes as employed in our own Laboratory of Biology. Here you will find every means for investigating this subject, and I hope you will avail yourselves of the facilities offered for practical work.

The term *bacteria*, or *microbe*, refers to minute particles of matter, microscopic in size, which belong to the *vegetable* kingdom, where they are known as *fungi*. If we examine a drop of decomposing urine under the microscope, amplifying say four hundred diameters, the field is seen swarming with minute bodies, some mere points, others slightly elongated into rods, all in active motion, rising, falling, oscillating—a ceaseless confusion. If the water be allowed to evaporate, all becomes still, and the slide seems covered with mere dust. Apply a drop of water, and after a short time the little, dried-up granules again show their activity, as though nothing had intervened to disturb their vocation. Similar minute forms are seen in every decomposing fluid, often in the blood and sputum of healthy persons. The air is full of them; the dust of our dwellings abounds with their spores in countless numbers, only awaiting suitable conditions to start into active and rapid reproduction. As I have said, certain forms are found in the blood of healthy persons, while other forms are found in the blood of disease.

All these different organisms have become familiar to us under the generic term *bacteria*, which is a very unfortunate use of the term, as it really applies to only a single class of *fungi*. Cohn, whose classification I think is the simplest and the best, calls them *schizomycetes*, and makes the following classification:

CLASSIFICATION OF SCHIZOMYCETES (BACTERIA).—1. *Sphero-bacteria*, or micrococci. 2. *Micro-bacteria*, or bacteria. 3. *Desmo-bacteria*, or bacilli. 4. *Spiro-bacteria*, or spirillæ, spirochetæ.

I will now briefly refer to the more important features of each of these classes.

First, of *sphero-bacteria*, or micrococci. This is the simplest of the fungi, and appears as a minute organism of spherical form. It multiplies by fission—a single coccus forming two—these two producing four, and so on. They present a variety of appearances under the microscope, as you will observe in Fig. 1. From single isolated specimens (which under the highest magnifying powers present nothing beyond minute points), you will observe them in pairs, again in fours, or in clusters of hundreds—yes, thousands (forming zoöglœa), and still adhering together, forming chains.

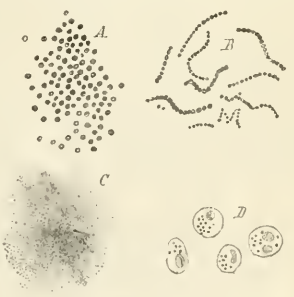

FIG. 1.—Sphero-bacteria (Micrococci): *A*, Micrococcus vaccinæ (× 1,000); *B*, same in chains (× 650); *C*, a zoöglœa mass; *D*, M. gonorrhœa (× 600).

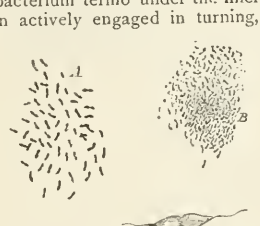
When a given specimen is about to divide, it is seen to elongate slightly, then a constriction is formed, which deepens until complete fission ensues. Micrococci possess no visible structure. They consist of a minute droplet of protoplasm (myco protein), surrounded by a delicate cell-membrane; certain forms are embedded in a capsule. (Diameter, .0008 to .001 millimetre.)

These little organisms, when observed in a fluid like blood, sputum, etc., are found to present very active movements, although provided with no organs of locomotion. This Brownian motion is possessed by almost every minute particle of matter, organic and inorganic, and is not due to any inherent power of the individual.

Micrococci are almost omnipresent. They are always found in millions where moist organic matter is undergoing decomposition. They are associated with the processes of fermentation, in fact, they are essential to it. The souring of milk succeeds the multiplication of these germs. They abound in the air, the earth, the water. Certain varieties are pigmented, and you will observe colonies of these *chromogenic* cocci multiplying in our laboratory upon slices of boiled potato, egg, etc., presenting all the colors of the rainbow. Fortunately, all of these germs are not associated with, or rather are not the cause of disease. Certain species, however (termed *pathogenic*), are always associated with certain diseased conditions.

The second plate which I present (Fig. 2), illustrates the microscopical appearance of the *Bacterium termo, micro-bacteria.* You observe that they are slightly elongated, and inasmuch as they multiply by division they frequently appear coupled together, linked in pairs, and in chains. They are generally found in putrifying liquids, especially infusions of vegetable matter. They possess mobility to a remarkable degree. Observing a field of the bacterium termo under the microscope they may be seen actively engaged in turning, twisting, or



IG. 2.—Micro-bacteria (Bacteria). *A*, Bacterium termo; *B*, same in zoöglœa mass (× 600); *C*, same (× 2,100) showing flagella.

oscillating—a delicate tail-like filament, or *flagellum*, has been demonstrated as attached to one or both extremities. This is too minute to be generally resolved, even if it is a common appendage.

Micro-bacteria are of various kinds, and although many are pathogenic, the *bacterium scpticæmiæ* of Koch produces the most rapidly fatal results when introduced into the circulation of a living being. Other examples of this class, resembling in every respect, as far as their microscopic features are concerned, the septicæmic bacterium, are frequently found in the blood of perfectly healthy persons.

Desmo-bacteria (or bacilli) are rod-like bacteria, occurring of various lengths and of different thickness. On this account authors have introduced the term *vibrio*, as applied to the long, slender, curved, and thread-like bacillus; bacilli are not infrequently provided with a flagellum, which assists in locomotion. The different species of bacilli differ greatly in their microscopic appearance; while some are rounded at their extremities, others are square cut, and others pointed. Bacilli may develop by division, but their usual mode of development is by spores. You will observe in Fig. 3 the bacillus of tuberculosis and anthrax. Notice at intervals the dots, which represent the spores from which, as the rods break up, future bacilli are developed.

Spiro-bacteria. In Fig. 4, I present to you drawings of two different forms of spiro-bacteria—the spirilla and the spirochetæ. The former have short, open spirals; the latter long and closely wound spirals. The *spirillum volutans* is often found in drinking-water and, in common with some other specimens of this class, is provided with flagella, sometimes at both extremities, which furnish the means of their rapid locomotion. The spiro-bacteria multiply by spores, although little is at present known of their life-history. They not infrequently are attached together at their extremities, forming zigzag chains.

In this brief description of the principal varieties of bacteria (classified according to their form), we have

Fig. 3.—Desmo-bacteria (Bacilli). *A*, Bacillus tuberculosis (× 2,000); *B*, the same (× 350); *C*, Bacillus anthracis, from the blood in splenic fever (× 750); *D*, Bacillus leprœ, showing bacilli in cells isolated from tuberculous nodules by teasing (× 1,000).

seen that they differ greatly in appearance, from the minute dot of the micrococcus and the elongated dot of the bacterium proper, to the elongated rod or cylinder of the bacillus and the long spirals of spiro-bacteria. It is unfortunate that these minute forms of life are not sufficiently constant in habit to always attach themselves to one or the other of these genera. The micrococcus has a habit of elongating until it is impossible to recognize him except as a bacterium; while bacilli break up until their particles exactly resemble the micrococci. Again, there are other forms which cannot be classified with the above; but I will not at present burden you with the complicated forms of *fungi* which are found existing as moulds, yeast-plants, etc., but will pass to the consideration of the *biology of bacteria.*

Bacteria cannot exist without water. Certain forms require oxygen, while others again thrive equally well without it; some thrive in solutions of simple salts, while others fastidiously object to anything less than broths of albuminoid material.

The most important element in the successful multiplication and growth of fungi seems to be the maintenance of certain temperatures. The temperature of the hu-

man body is necessary for certain pathogenic bacteria, while ordinary temperatures serve for many varieties. Still there are points above or below which all cease to live. Immersion in boiling water rapidly destroys most forms, while prolonged boiling is fatal to all. It appears that while many forms of fully developed germs are easily destroyed by a temperature much less than 212° F., their spores are capable of withstanding high temperature with less risk of injury. The peculiar behavior of

each species under observation, must, as regards the effect of heat, be carefully determined, ascertaining the most favorable temperature for their development, and the degree of heat necessary for their destruction. If the conditions of temperature, media, etc., are observed carefully they will develop with extreme rapidity.

In the study of the relation of a given bacterium to a certain disease, it becomes necessary to attend carefully to three different operations.

First, the organism supposed to cause the disease must be found and isolated.

Second, it must be cultivated through several generations in order that absolute purity may be secured.

Lastly, the germ must be again introduced into a healthy living being.

If the preceding steps be successfully carried out, and the original disease be communicated by inoculation, and the germs be again found in the diseased body—we have no alternative—we must conclude that we have ascertained the cause of the disease. The importance of being familiar with the etiology of disease before we can expect to combat it with any well-grounded hope of success is evident.

The three steps I have alluded to are surrounded with difficulties, and if you will follow me I will endeavor to indicate some of them.

Let us suppose, for example, that we wish to repeat the work of Koch with the bacillus of tubercle. Let me premise by saying that it is believed that certain little rod-like forms are invariably found associated with tubercle. If the sputum of a phthisical patient be submitted to the skilled microscopist he is always able to demonstrate the bacilli. This goes for very little. Because bacilli are found in phthisis it is no more certain that they are the cause of phthisis than is it certain that cheese-mites are the cause of cheese. But if with these bacilli we can inoculate a person, and thus produce tuberculosis, we have the chain complete.

Well, supposing we were to inject some sputum from a phthisical person into the blood of a healthy person, and then boldly announce to the world that you have demonstrated the relation of cause and effect between the bacilli and phthisis. You would start such an uproar of objection as would speedily convince you that there was much work yet for you in the domain of bacteriology.

Among these objections would appear this, and very properly too: "You have injected into the blood of your unfortunate patient pus, morphological elements, and, perhaps, half a dozen other forms of bacteria with the sputum, any one of which are just as likely to produce the lesion as the bacillus you have selected."

So you must begin again. You must first isolate your bacillus.

It is a fortunate fact in the biology of bacteria that nearly every specimen has a peculiar mode of growth. If I were to take a glass plate, one side of which is coated with a thick solution of hot, peptonized gelatine, and allow the latter to cool, the gelatinous matter will become solid. If, now, with a wire dipped in some tuberculous matter, I draw a line along the gelatine, I have deposited at intervals along this line specimens of T. bacilli. If this plate be now kept at a proper temperature, after a few days, wherever the bacilli have been caught, a grayish spot will appear, which, easily seen with the naked eye, gradually spreads and becomes larger. These spots are colonies containing thousands of T. bacilli. It is not probable, however, that we have been fortunate enough to have avoided depositing other germs along the line. If putrefactive bacteria are present, they will liquefy the gelatine. Various appearances are thus afforded, even to the naked eye, according to the particular bacterium present, and we soon become familiar with the characteristics of particular germs. Cultures of bacteria are usually made in test-tubes containing peptonized gelatine, coagulated blood-serum, etc.

Let us return to our gelatine-plate. We find a spot which answers the description of a colony of tubercle bacilli. We now take a minute particle from this colony on a wire and convey it to the surface of some hardened blood-serum in a test-tube. We plug the tube so that no air-germs may drop in, and place it in an incubator at the proper temperature. After several days, if no contamination be present, a colony of bacilli will appear around the spot where we sowed the spores. Let us repeat the process: take a particle from this colony and transfer to another tube; this is our second culture. This must be repeated until we are satisfied that we have secured a "pure culture." If this be carried to the twenty-fifth generation, we may be assured that there remains no pus, no *ptomains*, nothing but the desired bacilli. It is a proper material now for *inoculation*.

Practically, many precautions have to be thrown around every step of our work. You can see that spores might accidentally be attached to our tubes. They must be *sterilized*. This is accomplished by exposing them to prolonged high temperature in an oven. Similar precautions are taken with the plug of cotton used to stop the mouth of the tube. The wire must be heated to redness always just before using. We are in constant danger of contamination, and sometimes fail even with the utmost care. Fortunately, we can determine whether everything is as it should be. If a tube shows signs of admixture, it is discarded at once and another trial made.

Negeli has proposed a "dilution method" for obtaining "pure cultures." He had some urine containing large *micrococci* which he wished to cultivate. The urine also contained numerous *bacilli*. A single drop of the urine, supposed to contain five hundred thousand bacteria, was mixed with about two ounces of pure water and shaken thoroughly. This dilutes the urine a thousand times. One drop of this is now mixed with another two ounces of water, and a millionth dilution was obtained, in which every drop must average to contain one bacterium. He inoculated ten tubes of gelatine each with one drop of this dilution. After incubation it appeared that four tubes remained sterile, one contained bacilli, and five the *desired cocci*.

You will find in our Biological Laboratory the modern appliances for sterilizing the fluids, vessels, etc., as well as several incubating ovens, the temperature of which may be maintained at a given point for months. The large incubator constructed by Dr. Miller, will accommodate several thousand culture-tubes at once.

We have, then, finished the second step in our work, that is, we have obtained our bacilli pure, and have cultivated them through several generations, and it is improbable that our culture-tubes contain any contamination from the original source of our supply of bacteria.

It remains for us to complete the work, that is, we must now reproduce the disease by inoculation with our pure culture. Now we are forced to resort to the lower animals for experiment. No one, as yet, has sufficient admiration for science to inoculate himself. Hence it is impossible to complete a perfect chain of evidence. Objection can be reasonably made to the employment of mice and guinea-pigs. It is just possible that deductions from such experiments would not hold with human beings. But there seems to be no alternative. We proceed to inoculate several guinea-pigs with our pure culture of tubercle bacilli. The following are the results as first obtained by Koch, and which are almost identical with the phenomena obtained in our own work. The utmost care having been taken to avoid contamination of our virus (by heating the inoculating needle red-hot just before using), a puncture is made through the skin and a few drops of pure culture injected into the loose areolar tissue of the neck.

"The wound generally closes on the second day. The inguinal and axillary lymphatics become swollen on the eighth day. From this time the animals lose weight

rapidly, and die in four or five weeks from the time of inoculation. In the spleen and liver the characteristic tubercular changes are found." Koch's results led him to believe that "the bacilli occurring in tuberculous substances were not merely the attendants of tuberculous processes but the cause of them, and that *the bacilli actually represented the true tubercle virus.*"

I have spoken thus of the tubercle-bacilli in order to give you a general notion of the processes employed, and the precautions necessary in this work. The steps are nearly the same with the bacteria found in other diseases. The same extraordinary precautions are always necessary to avoid contamination. Some thrive in one fluid, some in another, some at ordinary temperatures, some at the body-heat.

From my remarks thus far you may have inferred that it is a very easy matter to find the bacterium of any particular disease, but I must correct this error. Let us place a particle from the discharges of a cholera patient under the microscope. Among the objects filling the field are numerous little curved rods—the comma bacilli. But if you now substitute a drop of fresh normal saliva for the choleraic discharge, you will find little curved rods in every respect like the commas of cholera. I may as well say at once that the microscope alone will not enable us to determine whether a given bacterium is pathogenic or not. You have already seen that each species possess peculiarities of growth in our culture-tubes.

Bacteria also frequently afford peculiar chemical reactions. For example, nitric acid will discharge the color from all bacilli, artificially dyed with anilin, *except those of tubercle and anthrax.* One species is stained readily with one dye, that leaves another unaltered. Thus we are enabled in the laboratory to determine whether the bacilli found in sputum, for example, are from tubercle or are the bacteria of decomposition.

From what I have said of the tubercle bacillus it would seem as thoroughly demonstrated that it was the cause of tubercle in these animals. But we must walk cautiously here. These are not human beings; who knows that like results would follow their inoculation? The animals used by Koch are animals very subject to tubercle.

We must, from the very nature of our environment, be constantly inhaling these germs as we pass through the wards of our hospitals—yes, they are floating in the air of our streets and dwellings. It becomes necessary for us to inquire, If bacteria cause disease, in *what manner do they produce it?* Ziegler says: "The healthy organism is always beset with a multitude of non-pathogenous bacteria. They occupy the natural cavities, especially the alimentary canal. They feed on the substances lying in their neighborhood, whether brought into the body, or secreted by the tissues. In so doing they set up chemical changes in these substances. While the organs are acting normally these fungi work no mischief. The products of decomposition thus set up are harmless, or are conveyed out of the body before they begin to be active." If bacteria develop to an inordinate extent, if the contents of organs are not frequently discharged, fermentation processes may be set up, which result in disease. Bacteria must always multiply and exist at the expense of the body which they infest, and the more weakened the vital forces become the more favorable is the soil for their development.

Septicæmia is caused by the absorption of the products of putrefaction induced by bacteria. Before bacteria can multiply inside or outside the body they must find a congenial soil. The so-called cholera bacillus must gain access to the intestinal tract before it finds conditions suitable to colonization. They do not seem to multiply in the stomach or in the blood, but once injected into the duodenum they develop with astonishing rapidity. The delicate epithelial cells of the villi become swollen, soften, and break down, exposing the mucosa.

But it becomes us to proceed in this matter with great caution. We must avail ourselves of every means of research, and patiently endeavor to ascertain what of pure gold there is in this new field of study. The subject is a fascinating one, and it seems to settle, or at least, open the way of settling, so many hitherto difficult questions in pathology, that it has been accepted by many without such a basis of facts as every careful investigator should demand. Another very extensive and important field opened by bacteriology is that of the prevention of disease by inoculation of attenuated or modified bacterial matter.

Pasteur, experimenting with the bacilli of anthrax, found by exposing the microbes to a certain temperature higher than that most favorable for their development, they lost their virulence to such an extent that he could vaccinate sheep without danger; and that animals so vaccinated were, for a given time, rendered incapable of contracting anthrax. Various opinions are held regarding the value of these experiments at present. You are all familiar with the newspaper accounts, at least, of Dr. Ferrán's experiments with the cholera inoculation. We are not at the present time able to speak with any degree of positiveness regarding the value of this work.

What is to be the future of the very interesting and fascinating studies to which I have this afternoon briefly directed your attention, no one as yet can determine. It is in the hands of ardent students, who are everywhere carrying out new investigations, and I shall not burden you with my own opinions in regard to it. The great question at present to be settled is, whether we are about discovering the ultimate cause of many hitherto obscure pathological states, or whether these microbes are only bacteria of health taking advantage of diminished vitality to develop with increased rapidity—*whether they are the cause or the scavengers of disease.*

Original Articles.

COMPRESSION MYELITIS OF POTT'S DISEASE SUCCESSFULLY TREATED BY LARGE DOSES OF POTASSIUM IODIDE.[1]

By V. P. GIBNEY, A.M., M.D.,

PROFESSOR ORTHOPEDIC SURGERY, NEW YORK POLYCLINIC.

THE paper this evening is presented with the object of recording a few cases of interest from a therapeutical standpoint. If any claims to originality are expressed, I beg that the claims will be freely criticised, and, if unfounded, corrected.

I am not aware that anyone has employed the drug in the doses that I have employed it in this disease, and with the same success. I confess, at the same time, that I have not searched the literature of the subject with that diligence that a paper laying claim to originality demands, and my apology is simply lack of time.

A few years ago, 1878, I had the honor of presenting before the Neurological Society a paper on "The Paralyses of Pott's Disease," being a clinical study of fifty-eight cases, and at that time I made a very careful search of the literature, failing to find any mention of potassium iodide in large doses as an efficient remedy. From a study of my own cases, and from the writings of Michaud,[2] I arrived at what I still believe to be the correct pathology of the compression myelitis of Pott's disease. Let me quote from my paper, as I do not believe I can do better now, seven years later:

"A study of the symptoms peculiar to lesions of the different tissues in the neighborhood of the diseased vertebræ, aided by a knowledge of the facts taught by neurophysiology, enables one to state with a great degree of precision the pathology in individual cases. In modern

[1] Read before the Section on Neurology of the New York Academy of Medicine, October 9, 1885.

[2] Sur la Meningite et la Myelite dans le Mal Vertebral. Paris, 1871.

text-books we have chapters on peripachymeningitis, on pachymeningitis, on meningitis and the inflammations of all such organic structures. The subject of neuralgia, and of pseudo-neuralgia, is constantly before the profession in many entertaining forms. The theory of the French school of pathologists is well fortified by the facts collected, and when one is satisfied as to the mode of reproduction of the impaired nerve elements, it (the theory) becomes easy of acceptation.

"Let me state as clearly as I can the theory. First there is the caseous osteitis of the bodies of the vertebræ, attacking by contiguity the perimeningeal areolar tissue, the vertebral ligaments, of course, becoming involved in the morbid process. Then the dura mater speedily partakes of the pathological changes—a "pachymeningite externe" being the result. This change is characterized by vegetations on its external surface and consecutive caseous alterations, which blend with the caseous detritus in the bone and thickening of the dura just named, from a chronic inflammatory process. The cord becomes compressed, a focus of myelitis is, as a consequence, induced, and from this focus there is a transverse myelitis followed by a fasciculated sclerosis ascending through the posterior columns, and descending through the lateral and anterior.

"This caseous external pachymeningitis in Pott's disease as a constant factor readily explains many of the symptoms peculiar to peripheral neuralgias and paralyses. Michaud believes that in all cases of angular deformity *myelitis* is the rule, and states that it may exist without giving immediate rise to paraplegia, claiming to have proven that myelitis is early in its development, and may even precede the paralysis.

"From a clinical study of the cases now under consideration, I think I can approximately arrive at the different lesions. *Three* seem to have been due to direct pressure from the bony angle itself; *twelve* gave the history and progress of cases of reflex paralysis due to obstruction of the blood-supply; the *remaining number* were, I believe, from a myelitis by slow compression."[1]

A modification of the pathology then taught has been made by the extraordinary researches in bone tuberculosis within the past two or three years. I have little hesitation now in pronouncing the osseous lesion a tuberculosis of the vertebræ, and whether the inflammatory processes induced by contiguity and extension are of a tuberculous nature I confess my inability to decide. Whether the pachymeningitis, the meningitis, and the myelitis are tubercular or non-tubercular, this question, I think, has not been settled by pathology. The cases of spontaneous recovery and the cases of recovery under this treatment and that, would seem to militate against a tubercular hypothesis. Furthermore, the most ardent disciple of Koch, I am sure, will admit the existence of non-tubercular dependent upon tubercular inflammation. At that time the remedies on which we placed reliance were fixation and traction, blistering, the actual cautery, ergot, belladonna, nitrate of silver, and potassium iodide in moderate doses. The results obtained were not such as enabled me to speak with confidence of the remedies either singly or in combination. I had made myself familiar with the natural history of the paralysis of Pott's disease, with cases that had recovered spontaneously after all treatment had been abandoned, and this knowledge had made me skeptical to an extreme degree. The pathology was well rooted in my mind and I entertained strong hope that some remedy would yet be found that would enable us to speak with more positiveness in giving a prognosis in a given case.

A paper read by Dr. Seguin at a subsequent meeting of the Society on large doses of potassium iodide in chronic nervous lesions not specific in nature, and the discussion which followed the presentation of his paper, directed my attention to this drug as the possible solution of my problem.

[1] Journal of Nervous and Mental Disease, April, 1885.

An opportunity was not offered until August, 1883.

A man, thirty years of age, by occupation a plasterer, applied to me for relief from an incomplete paraplegia depending upon a compression myelitis in the upper dorsal region. He dated his spinal disease from a severe fall fourteen years before. Apart from the few symptoms pointing toward spinal concussion he suffered no material injury. He soon recovered, to all appearances, and ten years subsequently after much exposure as a Texas "cow-boy," he first complained of symptoms indicative of spinal caries. There were epigastric pains, tenderness on concussion, much rachialgia, and a stooping gait. A thirty-mile ride on horseback at this time was described as agonizing. On his way to New York by steamer, he found relief only in the prone decubitus. Finally, he came under Dr. Sayre's treatment in Bellevue Hospital, where it seems his disease was first recognized. The relief from the plaster jacket was prompt and decided. The treatment was continued a year and he fancied himself cured. In two more years a relapse came on and the loss of power in the lower limbs was of one month's duration when he first came under my observation. A well-marked bosse was seen in the dorsal region and he suffered from paræsthesia in the limbs, and paresis of the vesical sphincter. The reflexes were greatly exaggerated and he could with difficulty stand. Locomotion by the assistance of two canes was barely possible. I immediately began the iodide in ten-grain doses and took steps to secure a spinal brace as speedily as possible. The Paquelin was employed. At the end of a week the apparatus was applied and he was soon taking thirty grains of the potassium three times a day. Vichy was used as a vehicle for the drug and his stomach rarely ever rebelled. Within a month the improvement was decided and by the middle of November he was able to walk with much ease. The maximum dose he reached was forty grains three times a day.

By the beginning of the year he was attending business again, yet he still continued the iodide in the doses above mentioned. From that time to the present he has been engaged quite actively, and has learned to promptly check any symptoms of returning paresis by a recurrence to the potassium in gr. xx. doses. The steel brace was substituted by a plaster-of-Paris corset, and this by the leather jacket. Three months, it will be seen, were required in which to bring about a cure.

Contrast this with a case in a male child, aged four, I first saw in May, 1882. This child came of a family in which phthisis existed, and with this diathesis as an inheritance had developed spinal caries four months after an attack of measles. The signs first observed were so like those of a lateral curvature that the case was thus diagnosticated by the family physician. A plaster-of-Paris jacket was applied, but it was not until the close of September that the patient was placed under my care. Signs were then suspicious of cervico-dorsal disease, instead of lumbar disease for which he was treated. All doubts were dissipated by November 1st, when a deformity in this region appeared, and explained at the same time the previous dorso-lumbar lateral curvature. A month later he began walking poorly, and complained of pains in the limbs. The reflexes were exaggerated, and areas of anæsthesia were discovered.

I immediately took the following precautions: Secured a head-support permitting no weight whatever to come on the cervical and upper dorsal spine; saw that he kept his bed, and under no circumstance was he allowed to stand or sit up; did not permit the mother or anyone to adjust the brace or head-spring, attending to this myself as infrequently as possible.

I ordered bromide of potassium to be taken at night when he was specially restless, and had him take belladonna carried to the physiological effect. As a matter of fact he seldom took the bromide; gave cod liver oil and plenty of nutrients generally. Faradism was administered daily. I gave as prognosis, recovery from the

paraplegia under such circumstances within six or eight months. Nothing eventful occurred until the following July, when improvement began, and by the middle of August he was able to move the limbs about freely. I did not allow him to stand or to make any attempt at walking until September. His recovery has been exceedingly slow, and despite the most assiduous care there is now a kyphosis three-fourths of an inch on a chord of five.

One of these cases was in an adult, the other in a child. In one I had an incomplete paraplegia to deal with, in the other the loss of power was complete. In both, however, I had the intelligent and faithful co-operation of the patient and family.

In another case I did not have the co-operation of the patient, and the obstacles have been peculiarly trying.

Some time during the early part of 1883, a female patient, aged thirty, was referred to me at the Forty-second Street Hospital, out-door department. She was an inmate of the Nursery and Child's Hospital. Shortly after the birth of a child a dorsal kyphosis was discovered, and although the deformity was not very marked there was little or nothing in the way of a history to be obtained. She was supplied with a steel brace such as is used at the hospital, and special care was given to the accurate fit of the same. The suffering was not relieved to any great extent by the support given, and to relieve pain the Paquelin cautery was employed occasionally. Blisters, too, were used, and even with all this counter-irritation, narcotics had to be employed, so great was the pain she experienced during the exacerbations. The support was inefficient by reason of her persistence in removing the brace whenever she felt so inclined. I saw her very irregularly, and it was difficult to maintain any interest in her case. She seemed to grow worse, and the visits finally ceased.

In the spring of 1884 I was appointed a member of the visiting staff of the Nursery and Child's Hospital, and the first case to which I was called was my old case of Pott's disease. I found her with an increased amount of deformity and totally unable to get about the ward. I learned that she had been slowly losing power for at least three months. She had always been very stout and was consequently now a very helpless patient. The old brace was reapplied, and potassium iodide ordered. She rebelled against the potassium, claiming that it produced nausea. During the next twelve months she had routine treatment. Plaster-of-Paris jackets were used and gave adequate support. The potassium dosage got to be an old story, and some days she took small doses, some days large doses, and some days none whatever. Faradism was employed daily for months; massage was employed, and still she remained paraplegic. In response to my urging large doses of the iodide, I was invariably told that her stomach would not tolerate more than twenty-five or thirty grains three times a day. Mineral waters were used too as a vehicle, and every precaution seemed to be taken against the stomach disorder. It was asserted that she couldn't be kept quiet, that she would lift her child and do all manner of things that a good patient should not do. The lady managers discussed her case (the patient herself was very aggravating), and finally in solemn conclave they decided that "Mrs. K—— must go." This was about the first of March of the present year. It had been assumed that I regarded the case as incurable. The date of her going was not fixed, and the day after the above edict had been announced, I said to Dr. Hance, the resident physician, that if he would make this a personal matter, and see that Mrs. K—— got sixty- or seventy-grain doses of the iodide three times a day during the next ten days, she would be able to walk out of the hospital when the date of her discharge arrived, if it must arrive. It was well known, however, that the kind-hearted ladies who composed the board had no intention of carrying into execution their threat.

At all events, Dr. Hance set about his task with right good will, and when I called again, at the end of the ten days, he greeted me with the joyful report that Mrs. Kelly was able to move her feet about in bed, that she had stood with very little assistance, and that by the aid of himself and the nurse she had walked nearly one-half the width of the ward. The iodide had been pushed to drachm doses. Let it be remembered that the jacket she then wore had been applied two months before the date of our new departure. From that time to the present she has been gaining in power and in sensation, and her complete recovery is not far distant. The summer months are not good months in which to apply plaster-of-Paris jackets to persons of corpulent habit, and hence Mrs. Kelly has not had the attention in this respect that her case demanded. The iodide is still continued, but not in as large doses, the stomach is as tolerant of the drug as one can reasonably expect, and, strange to say, she seems not to have lost one pound of flesh.

Indeed, I am inclined to the belief that large doses of this drug tend to produce flesh rather than destroy it. I have never known a patient with compression myelitis grow thin under this treatment. A girl in Yorkville actually became obese, and I feared that a continuance of the drug might make her an object of envy for some dime museum. This is her case:

A girl, aged seven, of large build, and moderately stout withal, came under my observation in the out-door department of the hospital, January 30, 1884. She presented a kyphosis in upper dorsal region of one and one-fourth inch on a chord of seven, and the deformity was of two years' standing. The acute symptoms, for the relief of which she applied for treatment, were of recent date, and pointed to an exacerbation after a long period of immunity.

A steel brace was applied a week later, and on February 25th it was recorded that paraplegia was imminent, the reflexes being greatly exalted. A fly-blister was ordered, and a week later a head-spring was attached to the brace. At this time her paraplegia was nearly complete, and confinement to bed was ordered.

On March 12th, the symptoms having become more marked, potassium iodide in ten-grain doses was ordered, and by the 19th was increased to fifteen grains, three times daily.

It was observed that she was gaining rapidly in flesh, and was indeed becoming quite corpulent. The brace was a good fit, but the mother did not follow directions, and the child was dragging herself about the floor and up and down stairs without let or hindrance.

In April a diarrhœa was thought to be dependent upon the iodide, and the dose fell from twenty grains to ten grains. May 1st paresis of the vesical sphincter was observed, and a fortnight later there was marked diminution of sensibility. It was observed at this time, too, that the brace and head-spring were very imperfectly worn. She did not keep her bed, although the paraplegia was complete and her corpulency was still a notable feature.

The case was reported to me as making little headway, and one evening in July, I called to see if any cause could be found for this sluggishness. As I drove up to the door I saw my patient, "sitting out in the cool of the evening," enjoying the street scenes with quite as keen a zest as did any of her playfellows. She sat in the conventional high chair, with her immense limbs dangling below the step, while her head was fully released from the spring intended for its support. The brace about the body I found barely hanging by shoulder-straps and corset lacing.

I here saw quite plainly that I must expect no co-operation at this house, and I decided to apply as soon as possible a solid plaster jacket, and adjust the head-spring so that nothing could be removed. A few days later, at the Polyclinic, I succeeded in applying a good jacket

and headspring. I saw that she had a saturated solution of the iodide, and she began again on ten-grain doses. I insisted on having her remain in bed, but the order was very imperfectly carried out, and she sat up about as much as ever. The jacket had to be replaced by another after six weeks, by reason of her continued corpulency. She took the iodide now in forty-grain doses, and no stomachic disorder was observed.

On December 4th the mother reported that our obese patient was able to stand assisted by the wall only. A month later she was walking about the floor, and before the winter closed she walked up and down stairs. In May I examined her, and found that the recovery was complete. She has had no relapse.

It will be seen that this case improved, not immediately after the application of a jacket, but after the dose of the iodide had reached respectable proportions. I am as ready as any one to give the plaster jacket the credit it deserves. I am as enthusiastic as any one in my advocacy of fixation and rest for the diseased vertebræ, and I have observed cases wherein the improvement began only when these ideals were approximated. Take as an instance the following, which will also illustrate quite as well, I fancy, the value of the treatment we discuss this evening. Note, too, the encouragement one gets from a combination of external and internal therapeutics.

A female patient, aged twenty-one, was seen first in the out-door department of the Hospital for the Ruptured and Crippled, October 26, 1883. She worked in a silk factory. A history of pain in her back dated from the January preceding. A short time before that she had a fall, striking on her back. The pain, however, did not become severe until the beginning of September. At the time she presented at the hospital she complained of intercostal and abdominal pain, concussion caused pain in the dorsal region, and there was a kyphosis at the seventh dorsal spine of five-eighths of an inch on a chord of three and a half. The only region that showed any tenderness was in the lower dorsal. The Paquelin cautery was used freely, and a spinal brace ordered. Before the apparatus was completed, and three days later, the mother reported that she was very unsteady on her limbs, and walked with great difficulty. Numbness was first a marked feature four weeks from the date she came under treatment.

It was not until December 10th that another opportunity was offered for examination, when it was noted that the patella tendon on both sides gave morbid exaggeration of the reflex, that of left side giving the more marked. The ankle clonus was increased on both sides. The brace had already been applied and an excellent fit had been secured. My interest in the case was sufficient to insure her attendance at home, and one of my assistants was detailed to visit her as often as occasion demanded. My instructions were to employ the cautery at least once a week, to keep her in bed, and to give potassium iodide in increasing doses.

A note was made January 21, 1884, to this effect: She had not left her bed since December 10th, her digestion was good, general appearance ditto, but for the past three weeks the paraplegia had been complete, without involving, however, bladder or rectum. A pill, consisting of colocynth, belladonna, and nux vomica, once daily, had controlled the constipation. Clonic spasm of the flexors had been very annoying for a week. Cod-liver oil was borne well by the stomach. The cautery had been used as directed.

In March another note recorded excellent health, complete paralysis of motion, but with improvement in sensation. At this time she was taking belladonna and strychnia. The deformity had not increased, and the tenderness had disappeared. I find no record of any administration of the drug on which I had placed so much reliance. My own duties precluded the possibility of personal supervision, and as the assistant was an attaché of a neurological clinic, I left the case in his hands.

In the summer he did begin the use of the iodide, and reached by September twenty grains three times a day. The progress seemed so slow that I was led to make a change in the treatment. I found the girl in fair condition, and following directions religiously. The brace seemed to meet all the indications that were demanded, it was seldom removed and then removed and reapplied with extreme care; she kept her bed faithfully, and she was the embodiment of patience herself.

The deformity had not increased to any appreciable extent, but there was not the faintest trace of voluntary motion in limb, foot, or toe. The customary exaggeration of the reflexes, and the ordinary anæsthesiæ and paræsthesiæ were present. The sphincters were but slightly involved. The date of my observation was August 30th.

Assisted by my friend Dr. Hunter P. Cooper, of this city, I partially suspended the patient on September 2d, exercising the utmost care in this preparatory work, and applied a solid plaster-of-Paris jacket. Before leaving the house I saw that she had a saturated solution of the iodide, and ordered gr. xxx. t.i.d., to be increased rapidly to gr. l. The mother reported to me on the morning of the 5th, three days later, that our patient was able to raise the left foot from the bed. On the 15th I called at the house, finding her able to raise the left limb from the bed, and to flex the toes quite easily. The improvement continued, but at the end of a month she was still unable to walk. I found that the jacket had broken horizontally, and applied a new one [November 22d, soon after which, December 9th, she was walking about the floor with the aid of a chair. The subsequent notes simply record a continuance of the medicine in smaller doses (she had reached drachm doses), the occasional application of the cautery, the substitution this summer of a removable for the solid jacket, and an uninterrupted recovery.

A mere extended narration of cases would seem unnecessary, and yet I am very desirous of presenting another which shows the two methods of treatment in the same patient, who had two attacks of compression myelitis with an interval of one year.

Her case illustrates the value of faithful nursing, and that hearty co-operation of the mother with the physician in his management of the patient.

On April 6, 1883, a gentleman from Pittsburg, Pa., brought his four-year-old daughter to me at the Forty-second Street Hospital, and a classical history of Pott's disease in the upper dorsal region was furnished by the father in a letter received a week before. The disease was of one year's standing, and her ill-health at the close of her second year followed in the wake of measles with extremely tardy convalescence. Two or three acute exacerbations had occurred since the first signs of caries, and the present one began seven weeks before the little girl came under my observation. Loss of power was first discovered about March 10th, and within a fortnight the loss of power was complete.

The child's general condition seemed good, and but for the careful dorsal decubitus in which she was brought into the hospital one would not have suspected that the child was a sufferer from any disease. I found her, however, powerless in the lower limbs, and with this loss of power was an extraordinary amount of reflex excitability. A tap over the patella tendon, or over the body of the quadriceps femoris, or a slight sudden flexion of the foot would induce the most violent tetanoid movements in either limb. The sensation was much impaired, but the degree of anæsthesia was not measured.

The spinal deformity was in the upper dorsal region, the spinous process of the third dorsal forming the apex of the angle. The kyphosis measured three-fourths of an inch on a chord of seven inches. Spinal tenderness was present to a light degree. No time was lost in securing a good fit with a steel brace and head-spring, the object being to secure the maximum amount of fixa-

tion. Within a week the apparatus was applied, and the administration of belladonna was already a prominent part of the treatment.

Various paræsthesiæ were observed, such as: a burning sensation at times, cold sensation at others, the child complained of the presence of different foreign bodies between the toes, etc. Ergot was substituted a week later for the belladonna, and this in turn gave way to a stomachic and an alterative tonic. She occupied the bed, her mother's lap, and a rolling-chair in succession throughout the day, and no attempt was made to secure rest in the dorsal decubitus. From this time to June 1st the treatment varied. Blisters were used in addition to the different drugs employed, and she was allowed to go home, the further treatment to be conducted by mail.

The mother was instructed to keep the child in dorsal decubitus as much as possible. During the summer the parents became extremely solicitous, and other physicians were called in to examine and report. The recovery did not begin until the middle of August, and by the close of November she was walking.

A year subsequently, in November, 1884, she was brought to me for a new brace, report having preceded her that the gait was becoming unsteady again, and that she became tired quickly on the slightest exertion.

The brace was found broken and giving very inadequate support. The child complained of pains in the epigastrium and in the feet. Loss of power was manifest, and there was exaltation of the tendon reflexes. The general health was apparently good, and I could see no other cause for the return of the compression myelitis than the failure of the brace to give support.

I clearly prognosticated a return of the paraplegia, and went about the renewal of the brace as speedily as possible. At the same time I determined to give the iodide in as full doses as her stomach would tolerate. So we began on ten grains three times a day.

It was not pushed rapidly, because I did not have the same knowledge then in its tolerance that I have now. The dose was increased by two or three grains daily.

There was, in fact, very little iodide administered until a week after her return home. We lost valuable time in giving oil and anthelmintics, waiting to have the "road clear" for the potassium. In the meantime, although a new brace had been fitted, the loss of power was increasing from day to day. It was two weeks before she began taking her medicine with any regularity, and then the paraplegia was nearly complete. By the time she had reached twenty five grains, three times a day, the limbs were powerless.

This was December 10th. By the 17th she was taking thirty-five grains, and the reports were encouraging, *i.e.*, her stomach bore it well, and she was very happy, rarely complaining of pain or discomfort.

December 30th.—She takes forty-five grains, and her stomach bears the dose well. Still no return of power.

January 6th.—The dose not having been increased, it was observed that her stomach was disturbed, and that diarrhœa was present. For a day or two this dose was given only twice a day.

January 21st.—It was observed that she could move one foot feebly.

The dose was carried to fifty drops, and by the first week in February, she was able to bear her weight on the limbs. The compound syrup of the hypophosphates was begun about this time, and the dose of the iodide soon began to fall. By March 1st she was walking.

The subsequent history shows rapid progress, and a transfer of my notes to these pages is quite unnecessary.

I saw the patient in September of the present year, and could find no trace of the paraplegia.

From November 22, 1884, to March 1, 1885, I treated the case entirely by correspondence. A file of the letters written by the mother give to the case an interest as thrilling as that of romance.

It has been unnecessary to record the occasional stomachics, the infrequent doses of bromide of potassium at night.

I am quite sure that the iodide could have been administered in larger doses earlier and with much better effect. It occurs to me that the deposits or inflammatory thickenings which we seek to control, could be better controlled while they are yet new. In June I had an opportunity of testing this in the case of a little patient from Missouri. The test was not as thorough as I shall make when another occasion presents itself, yet I think a lesson can be learned from a study of the following:

A girl, aged two, came from the West, and was placed under my care June 17, 1885. She suffered from spinal caries, involving the upper dorsal vertebræ, and already a kyphosis had appeared. The first signs of compression myelitis were observed a week or two before she came under my observation. I found the reflexes on right side diminished, on left side increased. The loss of power was not marked, yet easily recognized. A removable jacket with headspring attached was worn, and was as serviceable as one of this nature could well be.

I applied a solid jacket as soon as possible, which was on the 24th. In the meanwhile the iodide was begun in five-grain doses, administered in dilute Vichy water three times a day. By July 3d she was taking twenty-five grains. She never became completely paraplegic, and while the loss of power increased until the date above mentioned, a return was then observed. In August she began to stand, and could raise her limbs from the bed and move them about in all directions with great ease. Two months from the date I first saw the patient I permitted the mother to take her home, the convalescing treatment to be carried out under the direction of the family physician.

In selecting a title for my paper, I purposely selected the terms, "large doses of potassium iodide," knowing very well that the doses I meant to record were not heroic by any means. I seldom give over one hundred and fifty grains in the day, and often I find it quite sufficient to give only a drachm. I do not believe in the sorbefacient effect of this drug in doses less than a drachm in the twenty-four hours.

In cases of compression myelitis the dose should be rapidly increased, and within the first week the patient should get from thirty to sixty grains three times a day. Dr. Seguin advocates its administration on an empty stomach. In the few cases in which I have attempted this mode the stomach has rebelled sooner than I had anticipated. I always, when practicable, employ Vichy or some other mineral water, as a vehicle, and I seldom have any complaints about nausea. Occasionally a diarrhœa seems to depend on the dosage employed. One cannot lay down any hard and fast rules. Individuals differ, and the dose for one is not the dose for another.

Children, as a rule, are remarkably tolerant of the potassium iodide. One hundred grains three times a day for a child suffering from cerebral or cerebro-spinal disease is not looked upon as anything extraordinary by neurologists.

The results in the cases I have reported show that our prognosis as to time can be made much more favorable. Formerly I never dared give a mother any hope that her child would recover from the paralysis short of six months. I usually gave the prognosis that twelve months would elapse before the child would walk. It is well known that many of these cases hang on indefinitely and seem to resist all methods of treatment. It is also well known that cases occasionally recover within a few days after the application of a plaster-of-Paris jacket, or a brace of any kind, or after a lively cauterization. These cases lack many of the signs of compression myelitis, and may be due to reflex causes, to anæmia, or hyperæmia. Again, cases of pseudo-paraplegia, cases in patients who

do not walk because of the position of the body are cured promptly when this position is corrected.

From my former paper I take the liberty of quoting a paragraph bearing on the prognosis:

"Of the 58 cases, 13 have died, 6 dying from myelitis, 5 from other diseases subsequent to the establishment of a cure, and 2 from tuberculosis before the complete restoration of power to the limbs. The mortality, then, is about 10½ per cent. Twenty-nine recovered from the paraplegia; 8 of these relapsed, and all recovered again save 1, who is still under treatment, along with the remaining 14 still unrelieved."

A case, the notes of which were handed me by Dr. L. E. Holt, just as I was completing my paper, illustrates several points worth mentioning.

A colored boy, aged five, developed caries of the spine in the upper dorsal region, early in the winter of 1884. In March he became paraplegic, the bladder being affected but not the rectum. The paralysis lasted about eighteen months, when complete recovery took place. The patient was never under any treatment whatever, either for his bone disease or his paralysis.

Since I have used the iodide in the manner above described, I have been able to give a prognosis much more favorable both as to time and completeness of recovery. I seldom hesitate to name three months, four at the farthest, in which recovery will take place.

Let it be distinctly understood that I do not rely upon the drug alone. My patient must have an apparatus that will secure the maximum degree of fixation. The better the fixation the more rapidly the case will recover, other things being equal. Let me summarize the points in the management of a case of compression myelitis—points legitimately drawn from the experience I have recorded in this paper.

1. Secure at the earliest possible moment immobilization of the spine, especially in the neighborhood of the vertebræ diseased.

2. Begin with ten grains of potassium iodide in mineral water—Vichy, I think, is best suited for most cases—three times daily after meals.

3. Increase the dose daily by five grains, until the stomach shows signs of intolerance.

4. Maintain as large a dose as the stomach will tolerate until convalescence is fairly established.

5. Do not lose sight of the apparatus employed, and replace it without hesitation and without delay whenever its inefficiency is demonstrated.

6. Keep the patient in bed the greater part of the day, and if he goes out see that the recumbent, or at least a semi-recumbent position is maintained. Under no circumstances permit efforts at standing until convalescence is fully established.

7. See that the general health does not deteriorate while special treatment is pursued.

23 Park Avenue, New York.

Naples Ready for the Cholera.—According to a correspondent of the *London Times*, Naples, despite the scourging it received last year for its filthiness, is in but little better condition to resist the cholera now than it was then. The city has now an abundant water supply, but it would seem that little use is made of it either by the civic authorities or by private individuals. The streets and dwellings are, many of them, as filthy as a year's accumulation of dirt can make them. The authorities have, within a few weeks, ordered about two thousand wells of impure water to be closed, but the execution of this order is not yet. When cities or countries persist in endangering the safety of their decent neighbors by breeding pestilences, they should be taken in hand and forced to clean themselves. That would be something much more worth fighting about than the possession of a few islands in the Pacific, or a strip of land on the coast of Africa.

Clinical Department.

ANOTHER FAILURE WITH CHLOROFORM IN THE TREATMENT OF TAPE-WORM.

Dr. Herman Gasser, of Platteville, Wis., writes that he was called upon to prescribe for a young lady, eighteen years of age, who was suffering from tape-worm. She had been carrying the worm for five years, and had tried many physicians and many remedies, including kooso, turpentine, oil of male fern, and chloroform. The latter, either alone, or mixed with oil of male fern, had been tried four times without success. Finally Dr. Gasser had prepared a decoction of pomegranate bark, eight ounces to the pint, and gave it in two-ounce doses every fifteen minutes until five had been taken. Then the patient became drowsy and faint, and the remedy was discontinued. This attempt was successful. The worm, with its head, was discharged, and the patient has now been freed from her unwelcome guest for over a year.

Progress of Medical Science.

The Breasts of Male Consumptives.—According to M. Leudet (*The Lancet*, September 19, 1885) there sometimes exists a congestive swelling of the breast of male consumptives that is related to the pulmonary disease. There is no deposit of tubercle. The author has observed three cases of this mammary enlargement. The breast is first swollen throughout, and has the characters of a disk whose diameter is about three to five centimetres. The skin that covers the gland does not exhibit any change in color, and the subjacent connective-tissue is unaffected. After one gland has enlarged the opposite organ may be affected. Pain is experienced in the diseased gland and may radiate round the thoracic wall. This swelling is especially liable to occur on the side the lung of which is most diseased, or when pleuritic attacks are notably present. The swelling is regarded as due to a congestion the result of irradiation from the central disease. The lymphatic glands are not swollen. After lasting from one to several months, the swollen mamma returns slowly to its normal size; suppuration has not been known to occur.

Two Cases of Herpes with Motor Paralysis.—Dr. G. Waller reports two cases of herpes, in which motor nerves were affected. A widow, aged sixty-eight, had a painful patch of herpes, covering the whole of the right side of the face, stopping abruptly at the middle line. After some weeks, the herpetic spots and the pain disappeared, being, however, replaced by paralysis of the same side of the face, with loss of taste on the right half of the tongue. The other case was that of an old man, who had a herpetic eruption situated on the anterior aspect of the upper arm on the right side; this was accompanied with severe itching and a pricking sensation. Eight days after the appearance of the eruption, he found himself unable to raise or extend the arm. There was no pain or swelling in the muscles or joints, and the electric reactions were normal. The herpes and the paralysis both indicated the circumflex and musculo-cutaneous as being the nerves affected. The treatment was electrical, and brought the case to a successful termination.—*The British Medical Journal*, September 19, 1885.

Lipocardiac Asthma.—Under the name of "lipocardiac asthma," Professor Cantani (*London Medical Record*, August 15, 1885) gives an account of the affection described by him since 1864 as "fatty heart asthma." The patient is perhaps quiet in bed or in an arm-chair, when suddenly, without any apparent reason, the rhythm of his respiratory movements is disturbed. Little by little, sometimes almost insensibly, his respirations be-

come more frequent, shorter, and more profound, amounting at times to a laborious and even stertorous dyspnœa. Gradually the respirations become less frequent and profound, returning by degrees to the normal. Such attacks are usually short in duration; severe attacks last only a few minutes, and mild attacks only about two or three minutes. At first the outbreaks are unfrequent—about once a month, or three or four in the course of the year; and then they follow fatigue, muscular efforts, or emotional disturbance. As time wears on, the attacks begin to recur at short intervals and without apparent cause. The origin of these symptoms, according to the author, lies not in mere fatty hypertrophy of the heart, but in fatty degeneration of the muscular tissue of the organ. The symptoms show themselves when the heart begins to be tired. With this muscle, however, fatigue means impossibility to continue its work with its usual power. It requires, therefore, a brief period of relative repose, of less energetic contraction. This, however, involves a less complete emptying of the ventricles. Now, during this period of relative repose, of fatigue of the heart, the quantity of blood driven into the lungs by the right ventricle, and to the rest of the body from the left ventricle, is, for the time, diminished. Not merely, therefore, is there less blood oxygenated in the lungs, but the blood that is oxygenated is distributed more slowly throughout the body. This insufficient supply of blood to the tissues provokes a nervous erythism, or general hyperæsthesia. The recognition of lipocardiac asthma is important, inasmuch as the prognosis is much more unfavorable than in any other kind of cardiac asthma. It must be distinguished from angina pectoris, with which it is apt to be confounded, and with which, in fact, it is rarely conjoined. Another disorder of respiration with which it might be confounded is Cheyne-Stokes' respiration. Cheyne-stokes' respiration, however, is a symptom in various morbid states. It has a different pathogenesis and a different significance. In it there is apnœa; in lipocardiac asthma, on the contrary, there is only dyspnœa. Cheyne-Stokes' respiration occurs at brief intervals, and does not occur long before death. Lipocardiac asthma occurs at distant intervals, and may occur for many years before death. The treatment of lipocardiac asthma consists in improving the general health of the patient. Against the symptoms, digitalis, convallaria, valerianate of quinine, caffein, cognac, red wine boiled with canella, etc., may be useful. In fatty persons who are not too old, ferruginous preparations may be tried.

Epilepsy and Ear Disease.—According to M. Boucheron epilepsy may occur in consequence of various diseases of the ear, such as tubo-tympanic catarrh, otorrhœa, or lesions of the mastoid process or labyrinth. Convulsive attacks of this nature may be observed in childhood or in adult life. The prognosis is favorable, but relapses may occur coincident with relapses of the ear disease. The precursory symptoms of an attack are increased deafness, vertigo, a sensation of pressure within the ears, etc. It would thus appear that in man, as in the lower animals, the ear may be an epileptogenous region, excitation of the auricular nerves producing convulsive attacks.—*Revue Médicale*, September 5, 1885.

Phosphide of Zinc in Dysmenorrhœa and Sterility.—In Mathews Duncan's lectures on Sterility in Women, he places dysmenorrhœa in the list of the best demonstrated sources of, or attendants on, such conditions. But, even if we consider dysmenorrhœa the cause of the sterility, the question of the treatment of the menstrual difficulty does not in many cases admit of ready answer. Certainly there are cases of dysmenorrhœa which may be rapidly and satisfactorily treated by dilating the cervical canal, this dilatation being by double-bladed dilators, rather than by other means. But there remains a large number of cases that present no indication for this method of treatment, and which, of course, are not benefited if it be tried. Now, some of these may possibly be cured by the use of phosphide of zinc, as recommended by Decoux, who found this medicine useful in many cases of dysmenorrhœa and of amenorrhœa. Decoux narrates a case where it twice proved effective in curing sterility associated with the former disorder. In addition to the success of this medicine in dysmenorrhœa, amenorrhœa, and sterility, he has found it remarkably useful in cases of hysteria, ataxia, anæmia, and neuralgia. He gives two granules, of four milligrammes each, morning and evening. Only the crystallized preparation should be used, as the powder is inert. He states that its preparation is so difficult, that, with a single exception, one scarcely finds in commerce any but an impure product, which is partly or completely ineffective.—*Med. News*, September 5, 1885.

The Significance of the Spiral and Central Fibres in the Sputum.—Vierordt and Jacksch doubt, according to a recent publication on this subject, the specific nature of these fibres, and declare that they have also observed them in pneumonic sputum. Pell gives additional weight to the testimony of the stated observers by two cases under his treatment. The first case was one of pneumonia, in a woman forty-eight years of age, who for a number of years had suffered from asthmatic attacks. In the sputum were found spiral fibres, with and without central ones, and isolated central fibres, all embedded in mucus and pus-cells; besides, numerous Leyden's crystals were also present. After the sputum lost its pneumonic character the spiral fibres had also disappeared, and did not recur even later, when typically asthmatic paroxysms set in again. The second case was one of pneumonia, in a woman fifty-five years of age, who at no time had had any asthmatic affection. Spiral and central fibres were again found in the sputum. In the autopsy the spiral fibres were found not only in the larger and finer bronchi of the infiltrated lower lobe, but also in the non-infiltrated upper lobe of the right lung, while they were completely absent in the left lung. The spiral fibres being soluble in potash-lye and baryta-water, it follows that they consist largely of a mucous basis. A very satisfactory explanation for the peculiar spiral arrangements of these fibres has not yet been furnished. It is highly probable, however, that they are caused by the onward motion of a tough, elastic mass through a very narrow channel, viz., the finer lumen of the bronchioles under the influence of the ciliated epithelial cells, the unequal contraction of the bronchial muscles, and, finally, that of the diaphragm. The contents moving in the line of the least resistance is forced to make these spiral motions. The central fibres may be regarded partially as an optical delusion, partly as resulting from a stronger turning of the finest fibres and subsequently greater consistency of them.—*Therapeutic Gazette*, September, 1885.

Unilateral Œdema.—Dr. Bassi relates a case of serous infiltration, limited to one side of the body, recurring at every menstrual period, in a young woman of rather delicate health. The œdema was strictly limited to the right half of the body, but the coloration, temperature, and sensibility of the two sides were equal, except that the skin on the right side could be reddened by slighter degrees of irritation. Coincident with the external œdema there was an infiltration of the right lung, as evidenced by the physical signs. At the time of these attacks there was also complete anæsthesia of the cornea on both sides and of the isthmus of the fauces. The right ovary was painful. Examination of the urine gave negative results. The patient presented various hysterical symptoms. The cause of this intermittent unilateral œdema was obscure. The condition could not well be referred to vaso-motor paralysis since there was no elevation of temperature or redness of the skin on the affected side. After about a year's treatment with bromide of iron and hydrotherapy, the patient was much better, although the hysterical symptoms had not wholly disappeared. —*Rivista Inter. di Med. e Chir.*, July and August, 1885.

A Fall of Two Hundred and Fifty Feet without Severe Injury.—Dr. Evans relates, in the *Bristol Med.-Chirurg. Journal*, the history of a girl who attempted suicide on May 8th, by jumping from the Clifton Suspension Bridge. The bridge is two hundred and fifty feet high, and has been a favorite place for suicides. Sixteen persons have been known to have succeeded in self-destruction by making this same leap. One other only was picked up alive, but survived only thirty minutes. Twenty days after the fall the patient was considered convalescent and able to walk without pain. There was apparently no permanent injury. As far as the writer knows, no case of survival after a fall from as great a height as one hundred and fifty feet has hitherto been recorded, and considers this instance as probably unique.

Should Arsenic be Administered to Nursing Women?—The question whether an infant at the breast can be poisoned by its mother's milk, when the latter has taken a large quantity of arsenic, recently came up in a medico-legal case in Paris. Dr. Brouardel was called upon to investigate a case where an infant had died suddenly, and the father was suspected some six months afterward of having attempted the mother's life. The child's body was exhumed and found completely transformed into adipocere, so that the viscera could not be separated from the other part. An analysis *en bloc* was therefore made. The body weighed six and three-fourths pounds, and contained nearly a twelfth of a grain of arsenic. It was decided that this quantity could not have been derived from the clothing or the soil. To decide in what proportions, if at all, arsenic is eliminated by the milk, Fowler's solution was administered to wet-nurses in doses ranging from three to twelve drops. It was found that the milk contained a comparatively large quantity of arsenic after these doses had been taken for several days. As much as one-sixty-fourth of a grain could be obtained from about three ounces of milk. Experiments on animals, to determine the effects on the milk of one large dose, were not very conclusive, but it was shown that arsenic in these cases was constantly eliminated by the lacteal glands. The greatest care should, therefore, be exercised in giving arsenic to nursing women.

Cocaine in Sea-Sickness.—Dr. Manasseïne, of St. Petersburg, gives an interesting account of the employment of cocainum muriaticum in sea-sickness (*Berl. klin. Wochenschrift*, August 31, 1885). He argued from its usefulness in the vomiting of pregnancy, that it would likewise be of value in this bugbear of ocean travel. He made a voyage himself in order to test the drug, and, finding among his fellow-passengers a man and a woman who were especially prone to the malady, made the following observation: Upon embarking he administered to each every two or three hours a teaspoonful of a solution containing two and a half grains of muriate of cocaine in five ounces of distilled water, with the addition of a sufficient quantity of rectified spirits of wine. In spite of very rough weather for a period of forty-eight hours, both individuals escaped sickness for the first time in their lives. He also treated successfully a six-year-old child after it had begun to be sick, and a girl eighteen years of age who had been sick for twenty-four hours before the cocaine was given. Her case being severe, she was given a double dose every half hour, and the result is described as being "truly magical." She remained well during the rest of the voyage. Similar results followed in three milder cases. The writer thinks it justifiable to infer that in this drug we have a certain and harmless remedy against sea-sickness.

Dermatolysis Associated with Molluscum Fibrosum.—The relation of dermatolysis, or, as it was called by Valentine Mott, pachydermatocele, to fibroma molluscum, which has been suggested by dermatologists, has recently been aptly illustrated in a case reported in *The Indian Medical Gazette*, August, 1885. A laborer, aged forty, entered the Indore Charitable Hospital for the removal of a large pendulous tumor which hung down from the left mammary region, reaching the level of the great trochanter of the femur on the left side. Examination showed it to be a dermatolysis, or, as Kaposi calls it, elephantiasis telangiectodes. It was further discovered by Dr. Keegan, who reports the case, that the whole body was covered with fibroma molluscum. No part of the surface, excepting the palms and soles, was free from the tumors, which varied in size from that of a pea to that of a walnut. The disease had begun thirty years before as a small tumor the size of a pea, growing about two inches to the left of the mamma. The fibromata began to appear at about the same time, and quickly invaded the greater portion of his integument. The weight of the tumor on removal was found to be two pounds and six ounces, and consisted of thickened skin and connective-tissue well supplied with numerous vessels. In this case the disease appears to have been hereditary, as the patient states that his mother had a similar growth in the same situation, which, however, attained only about half the size of his own. The author believes that the disease is only an exaggerated form of fibroma molluscum, and thinks his opinion is strengthened by the fact that the pachydermatocele began in the same manner as the small fibromata.

When does Syphilis Become Constitutional?—Discussing this interesting question in the *Nordist Medicinskt Arkiv*, 1885, Dr. Pontoppidian states his belief that the first manifestation of syphilis (the chancre), in its early stage, is a local disease, but that the syphilitic virus will infiltrate the adjacent tissues and glands in a short time afterward. This period he places at two or three weeks. He claims that constitutional infiltration does not take place during the first stage, or period of latency of the syphilitic virus. In support of his views he reports five cases, out of a large number experimented upon at the Copenhagen Hospital, in which auto-inoculations were made. The following case will serve as an example, as they are all similar: L. A—— was placed in the hospital August 12th, with a small foul ulcer in the sulcus coronarius, and reported infected sixteen days prior. The second day the ulcer was cleaner but somewhat increased in size, with hard infiltration. Inoculation was then performed in three places upon the abdomen of the patient, which the fourth day was noticed as without effect. The sixth day the places of inoculation were hardly perceptible. The fifteenth day adenitis inguinalis was in existence. On the seventeenth day at the place of one of the inoculations a little red not elevated spot was seen. The nineteenth day induration was noticed; the red spot increased in size and was slightly elevated; no constitutional symptoms. On the twenty-fifth day the papule was about the size of a pea, elevated and hard; syphilis had then appeared. Syphilitic maculæ were seen on the tonsils, and slight enlargement of the glands about the neck. Constitutional treatment was resorted to. The fortieth day the local lesion, both on penis and places of inoculation, had disappeared. Here, what appeared to be a negative result, at first, developed, after a certain period of incubation, the characteristic signs of syphilis. If this second inoculation be performed before the initial sclerosis or chancre has had time to entirely poison the organism, the result remains negative at first, but the period of incubation being completed, a new sclerosis is developed. The writer quotes Wallace, Puche, Boeck, and others as having reported cases where secondary inoculation had given rise to one or more fully developed lesions, where the virus was taken from a chancre and inoculated upon the affected individual. From his observations he believes that the chancre thus obtained will disappear before full development if the inoculation be not performed in the early part of the secondary stage, from the fact that the infiltration from the first lesion has become universal.

Capsicum Annuum in Delirium Tremens.—Dulácska reports, in the *Pester Medicin-Chirurg. Presse*, four cases of delirium tremens treated with capsicum annuum. one of the cases was complicated with pneumonia, a second by extreme motor and psychical restlessness. The result in all the cases was more prompt than after giving chloral. Two grammes of the powder were given every hour; after the fourth dose sleep came on, together with profuse sweating, voidance of urine, and diarrhœa. The mode of action is surmised by Dulácska to consist in a reflex action of the intestinal irritation upon the pneumogastric, resulting in slowing of the heart's action. The venous circulation becomes more tardy and the consequence is sleep and profuse secretion of urine.

Multifœtal Pregnancy.—The following case is reported in the *Medizinskoje Obesrenije*: A peasant woman, twenty-seven years of age, has been married nine years, and has menstruated regularly every three weeks and six days since her fifteenth year. Pregnant six times, labor normal. The last menses occurred October 14, 1884. In February this year she applied to a medical man, as the abdomen had increased so much in size that respiration was impeded. It was ascertained that the uterus was considerably enlarged, of a rounded oval form, with the fundus at the level of the scrobiculus cordis. To the right of the linea alba feeble cardiac sounds were heard; on the left small portions of a fœtus could be felt. The birth of a dead child took place on February 28th, at 8 P.M.; a few minutes afterward a second appeared, both breech presentations; and some minutes later, three more children, with their heads presenting. They were all born enveloped in amniotic sacs. The four last lived a short time. There was one placenta, weighing 585 grammes, to the periphery of which the umbilical cords were attached. All the children were females, and corresponded in size to their period of growth, each weighing about 590 grammes, with the exception of the first, which weighed 934 grammes, and was 41 centimetres in length. Several fingers and toes were missing from the hands and feet.

Constituents of Brain.—Baumstark has examined the brain-substance of the horse by improved chemical methods, and finds that the soluble salts, albumen, and organic extractive matters are present in larger proportions in the gray than in the white matter, the nuclein, combined cholesterin and lecithin, are nearly equal in the white and gray matters, but the white substance contains a preponderance of neurokeratin, free cholesterin, and protagon, and the gray contains the more insoluble albumen and connective tissue. The phosphorus contained in the ash of the white and of the gray matter is about equal. The author has contrived to isolate and study the hitherto doubtful protagon in such a way as to establish its identity.

Treatment of Peri-uterine Hæmatocele by Electro-puncture.—At the meeting of the French Association for the Advancement of Science, held at Grenoble, in August of the present year, a paper was presented by MM. Apostoli and Doléris upon a new method of treatment of pelvic hæmatocele by negative galvanopuncture. A double advantage is claimed for this procedure. The first is that, if the negative pole be used, a soft, non-retractive eschar is formed and the resulting fistula remains patent for a sufficient length of time, while adhesions are formed between the pathological cavity and the mucous membrane. The second is that the electrical current causes a modification of nutrition and provokes a more or less rapid regressive action in the pathological formation. The puncture should be made as nearly as possible in the centre of the tumor, care being taken to avoid the uterus, intestines, or a large vessel. In order to determine the relations of the parts, a careful rectal and vaginal examination should be made. The current should be of the strength of one hundred milliampères, and the duration of its application should be from five to ten minutes. The Léclanché element is the one preferred by the authors. The negative pole is a trochar of medium size protected by a glass or caoutchouc sheath, and the positive pole a large cake of clay moulded over the abdomen or one of the thighs of the patient. Antiseptic precautions are used during the operation, and subsequently a strong solution of carbolic acid is injected twice a day into the vagina. The authors claim that, by the use of this method, a speedy cure of pelvic hæmatocele may be obtained, thus reducing very materially the gravity of prognosis. The operation should be performed at the earliest practical period. The danger of the procedure lies chiefly in the liability of wounding a large vessel and giving rise to hemorrhage, but this can usually be avoided by a digital examination made to determine the situation of any pulsating arteries.

Treatment of the Convulsive Cough of Children.—The remedies directed against the convulsive cough of children may be divided into 1, narcotics; 2, antizymotics; 3, purely empirical agents. 1. (*a*) Bromide of potassium has not verified its alleged value at the polyclinic of Berlin; one hundred and twenty-two cases came under observation, twenty-six were treated with this salt alone; six of these only improved under its use, while the duration of the malady was in no way shortened. (*b*) Belladonna is one of the oldest remedies used in this affection; three to four drops of an atropine solution of five per cent. are recommendable. Fifteen grains of the extract may be given after supper, and this dose increased every five hours, until one hundred grains have been ingested altogether. This remedy owes its great reputation to its power of modifying the course and intensity of the paroxysm, and of shortening the convulsive stage. (*c*) Opium has no specific virtues in this affection, and ought not to be administered. (*d*) Hydrate of chloral is employed by Lorey twice daily in doses up to fifteen grains, with gratifying results. (*e*) Lublinski (the well-known therapeutist of Berlin) combines the extract of belladonna and hydrate of chloral with very encouraging results. The butylate of chloral requires further clinical trials to give us a correct estimate of its therapeutic utility. (*g*) The same can be said of propylamine. (*h*) Atomized ether applied to the neck, with the view of influencing the trunk and branches of the pneumogastric nerve, is a remedy of doubtful effect. (*i*) Nitrite of amyl is inadmissible. J. Roubart recommends the continuous current to the medulla oblongata, especially in small children. 2. (*a*) Quinine, in the state of either the sulphate or the hydrochlorate, is recommended by many physicians. (*b*) Other practitioners praise phenic acid, given either by inhalation or internally, but there is little definitely known of the value of this drug. (*c*) Inhalations of oil of turpentine have repeatedly given good results. (*d*) Inhalations of petroleum are recommended by Lesser and Hildebrandt, though others doubt their value. (*e*) Salicylic acid and salicylate of sodium have given various results with different physicians, and do not hence appear to be reliable. (*f*) Porrot eulogizes the vapors of phenylate of soda in the sick-chamber. (*g*) Nothing positive is known of the corrosive sublimate in this affection. 3. (*a*) The extract of chestnuts, prepared from leaves gathered in the fall, is not a specific, but appears advantageous. (*b*) Oxalate of cerium, in a daily dose of forty-five grains for a child one year old, and of four drachms for a child of seven years, is well indicated and advantageously used. (*c*) Hydrochlorate of pilocarpine is more of an abortive than a specific, but is to be used in small doses. Cassel mentions still ammonium, calomel, the mercurial munctions, and tincture of myrrh, but none of these drugs can claim constancy and promptness of action.—*Therapeutic Gazette*, September, 1885.

Little drops of water,
Little grains of milk,
Make the little doctors
Of Homœopathic ilk.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, October 24, 1885.

A NOVEL VIEW OF MALARIA.

ONE of the most interesting problems in the whole range of medical science, and one which receives, and deserves to receive, the attention of some of the clearest thinkers of our day, is that presented by malaria in all of its manifold and erratic manifestations. Although, fortunately, in this latitude, the pernicious forms of malarial fever are, while by no means unknown, of comparatively rare occurrence, yet no small part of the physical ills from which we suffer can be referred directly or indirectly to the action of this poison. And in many portions of the globe not less than one-half of the mortality is due to this cause alone. But aside from the large part which this disease plays in the causation of human suffering and death, it is of itself an interesting subject of study. There are few other infections which are so proteiform in their manifestations, and so insidious in their progress as is the malarial, and it is equalled, if indeed it be equalled at all, only by the syphilitic and the tubercular. It is now very generally accepted, upon the authority of Tommasi-Crudeli, Klebs, Marchiafava, and others, that the malarial infection is due to the entrance into the organism of a special form of lower life, a schizomycete. But we are still in the dark as regards the mode of action of this parasite, for no satisfactory explanation has yet been vouchsafed us of the characteristic periodicity in the symptoms of malarial infection, or of the irregular forms which it so often assumes. For this reason any new theories, even if they be nothing more than guesses, are interesting, and, if advanced by men of scientific attainments and reputation for careful study, are worthy of some thought, however strange and improbable they may at first sight seem to be.

In the supplement of the *Gazzetta degli Ospitali* of July 12, 1885, is reported a lecture by Professor Arnaldo Cantani, in which he explains the theory held by him concerning the mode of production of the various types of malarial infection. Briefly stated, it is that the microbe of malaria, having gained admission into the organism, is carried to the spleen. The latter organ under this new stimulus suffers a disturbance of nutrition and increases in size. And the whole question of the febrile paroxysm, he says, depends upon the capsule of the spleen and the degree of elasticity of its contractile elements. When the capsule is yielding the organ increases little by little, but there is in no case access of fever, and we have the hypertrophied spleen of chronic malarial infection. When, however, the capsule is normally elastic it is stimulated by the presence of the malarial germs, and is excited to contract, squeezing the microbes out into the general circulation. Then a paroxysm occurs of chill, fever, and sweating. During the fever the micro-organisms are either destroyed or eliminated, and there follows a period of repose. But in the meanwhile the germs remaining in the spleen begin to multiply, the capsule is again stimulated to contract forcibly, and the blood is anew charged with the poison. Then comes the fever, and again a period of rest succeeds. If the spleen is normally sensitive the paroxysm occurs every day, for the strength of the contractile elements is speedily restored. But if the organ is less sensitive a greater stimulus is needed to excite a contraction, and a paroxysm occurs then only once in two or three days, the fever assuming a tertian or quartan type. Following out this line of reasoning the author accounts for all the various forms in which the malarial poison manifests itself.

This is an ingenious theory and serves not only to elucidate the vexing problem of malaria, but accounts also for the existence of the spleen and demonstrates its utility. For if there were no spleen to store up the microbes and squeeze them out as occasion requires, there might be no malarial fevers. We would suggest the extirpation of the spleen as a promising operation for the radical cure of malaria, and one that may in time assume a rank alongside of resection of the lung in pulmonary phthisis, or of decapitation for a cold in the head.

STARVING FEVERS.

IT was the wish of Dr. Graves that it should be written on his tombstone, "He fed fevers." It would appear to be the desire of Dr. Yandell, of Louisville, to have the opposite inscription, viz., "He starved fevers." In a recent number of the *American Practitioner* he gives some of his personal experiences upon this subject. He says: "While suffering from typhoid fever, during nine weeks I was delirious. Those weeks remain to this day a total blank, except in one particular, and that related to food. The recollection of my aversion to that is distinct. My nurse told me that I took food at no time without a remonstrance; that I not unfrequently flatly refused to have it, giving always as a reason that it was exceedingly distasteful to me. I made the same objection to every kind of drink other than water. I got no medicine, but was required to take milk, at first every three hours, then every two hours. I had frozen champagne, at about the same intervals of time. Three weeks after the delirium subsided, I stood on my feet for the first time. I am just as sure that food was given in this case oftentimes to my hurt, as it was always given against my inclination. Yet this was the practice of the time. And I fear it is far too much the practice of the present day. Since Tanner's protracted fast, I have been much less disposed than before to force food upon patients against their wishes. I have made some short fasts myself, in the hope of wearing out a rheumatism. My first attempt I continued for eleven days, taking in that time but three glasses of water a day. I felt no particular inconvenience from my abstinence. Last winter I fasted twenty-one days, also in a rheumatism, in which time I had not

more than a quart of milk, which I took hot. I cannot say that my disease was benefited in the least. But I was without appetite, was averse even to food, and, if I got no good from fasting, I at least escaped any of the inconveniences which might have ensued had I taken nourishment. In the last year I have treated five cases of typhoid fever practically without food, that is, without food except when called for, or when delirium was present, and then only when it was not refused."

Dr. Yandell is probably right in his view, that it is the practice of the present day to feed fevers and feed them well. Perhaps it is sometimes overdone; but, on the whole, it is safer to over-feed than to starve. Dr. Yandell is himself a personal illustration of the fact that overfeeding in typhoid does not kill. Typhoid fever is a long and exhausting disease. The tissues of the body are wasting with abnormal rapidity. It is rational to suppose that as much nourishment should be administered as can be digested, a point to be determined by watching the stomach, and by a careful examination of the discharges.

We feel very sure that the profession will never return to the practice of starving fevers, especially those which are long and exhausting. Yet it may be that Dr. Yandell's experience will prove useful in calling attention to the possibility of over-feeding, a practice which causes discomfort, if not absolute danger, to the patient.

ETHERIZATION DURING SLEEP.

It is settled beyond doubt that with extreme skill and care anæsthesia can be produced by chloroform in some cases during sleep. The possibility of accomplishing the same result with ether has, we believe, never been seriously discussed, and would seem *a priori* quite impossible. A case in which such etherization was successfully accomplished has, however, been recently reported in the daily papers. Two men, uncle and nephew, had been sleeping together for several days, when one morning the latter on awaking found that he had been robbed. Investigation led to the discovery that the uncle had purchased an ounce of ether, and had poured it on his nephew's pillow. While in a profound sleep, which he believed was induced by the ether, the thief stole the contents of his nephew's pocket-book, opened the window and made several ingenious arrangements in the room, so as to create the impression that it had been entered by some one from outside.

THE THEORY AND THERAPY OF OXALURIA.

The seeker after pathological certainty finds himself much baffled in studying the subject of the so-called oxalic acid diathesis. Dr. Prout first announced that the continuous and excessive excretion of oxalic acid in the urine, in the form of oxalate of lime, was accompanied by a peculiar train of nervous and dyspeptic symptoms, such as irritability, depression, hypochondriasis, flatulence, constipation, and palpitations. His views were endorsed by Golding-Bird, and became widely accepted. In 1845, Dr. Owen Rees threw doubts upon the correctness of Dr. Prout's views, and affirmed that oxalate of lime was formed after the excretion of the urine out of the ureters, and that its presence simply indicated lithæmia. Dr. W. R. Basham has subsequently confirmed the correctness of this view, which has of late years had its turn of popularity.

Dr. Dickinson does not accept the theories of either Dr. Prout or Dr. Rees in their entirety. Undoubtedly, he says, lithic acid in excess is a source of oxalate of lime, but in the condition known as oxaluria, where there is a long-continued excretion of pale, clear urine, rich in the oxalate of lime, the lithæmic theory is hardly sufficient, and the main fact of importance is the excessive excretion of lime and the other earthy salts. Oxaluria is not lithæmia, therefore, according to Dr. Dickinson, but it is a condition in which there is excessive loss of earthy salts associated with an active, restless, irritated nervous system. The term oxaluria might be abandoned, since the condition it designates is only a part or phase, a general condition (in which there is loss of earthy salts), and since most of these earthy salts are excreted in the form of phosphates. Dr. Dickinson reports cases in which the earthy salts are increased from an average of .003 per cent. to .03 per cent., or even .10 per cent., that is to say, from ten- to thirty-fold.

There has recently appeared in *Zeitschrift f. Therapie*, etc., an article by Dr. A Cantani, of Naples, on the subject of the "Theory and Therapy of Oxaluria." It is a very interesting contribution, in this respect at least, that it reproduces with a somewhat startling verisimilitude the early views of Prout and Golding-Bird. We do not wish to accuse Dr. Cantani of plagiarism, but if he has built up independently his views on oxaluria, it furnishes some corroboration of the old ideas as to the reality of such a condition as oxaluria.

Cantani states that oxaluria and oxalæmia (for he finds oxalic acid in the blood) is simply a symptom of a pathological condition in which the metabolic processes are at fault. The saccharine and oleaginous constituents of the food are not entirely oxidized into carbonic acid and water as they should be, but are in part changed into the incomplete end-product, oxalic acid. Oxaluria and oxalæmia are the anomalies of metabolism in which this process is simply slowed down. It is a kind of tissue laziness.

The most essential evidences of this disorder are, not the presence of oxalic acid in the urine or in the blood, but in certain clinical signs constituting a "symptom-complex" of the morbid state. These take on two phases, viz., (1) "oxaluria with hypochrondriasis and emaciation," and (2) "oxaluria with neuralgias and furunculosis." The first and severer form appears in persons of an irritable nervous system, the second and milder form in persons inclined to obesity. Under the first head, Cantani describes the familiar symptoms which have heretofore been usually associated with oxaluria as at first understood. Much the same category of symptoms has also been referred to neurasthenia and lithæmia.

With reference to therapeutics, Cantani follows with surprising closeness the views of Prout and Golding-Bird, viz., that the diet should be as near that of a diabetic as possible. He rigorously excludes almost everything but meat, fresh eggs, and soup. He even forbids green vegetables, and allows only a small quantity of milk. Out-door exercise, mountain air, and baths are recommended. In the way of medicines he prescribes

chiefly alkaline and saline draughts. In this he is supported by Niemeyer. On the other hand, the later English authorities advise mineral acids, strychnia, and occasional alkaline and mercurial purgatives. Neither Basham nor Dickenson believe in the need of a diabetic diet.

THE DOLLAR MEDICAL SHOP.

The task of reformers is generally a thankless one. They are compelled to fight against habit, indifference, and prejudice. Conscious of their own integrity of purpose, they press on, nothing wavering, until their aim is accomplished. This integrity of purpose is their solace at every rebuff and in every disappointment. It is in this spirit that we beg leave to say a few words more concerning the vexed "dispensary question."

That the prevalent methods of managing dispensaries tend to the abuse of medical charity, and to gross unfairness to the medical profession, no one denies. Many condemn these methods and hold themselves aloof from such institutions, but after awhile they are found in the places they formerly condemned, and justify their sudden change of heart under the plea of self-defence. The maelstrom has engulfed them. All that can be said of these prevalent methods of management is that they differ only in flagrancy, and at the head of the list in this respect stands, in our estimation, the Out-patient Department of the New York Hospital, which may justly be styled the "dollar medical shop."

Upon the payment of one dollar a patient is entitled to twelve visits to the dispensary for the ensuing month. As is learned from the annual report for the year 1884, five thousand one hundred and sixty-nine persons availed themselves of this imposition during that year, and the total number of visits was twenty-seven thousand, five hundred and sixty-five. Each patient paid for medicine from ten to twenty cents per visit. Splints and surgical dressings were furnished free. The average daily attendance in each class was about twenty. There are on the attending staff about twenty-five principals and assistants. The time spent by them there on the days of their service averages from one and a half to two and a half hours daily. This is what the profession is doing for the dispensary. What is it doing for the profession at large?

In the first place, it is not granting the full enjoyment of its clinical privileges. Out of all its classes, of which there is, if we read aright, one daily in each of the seven divisions, students are admitted, or, at least, publicly invited, to but three. All these facts call for some plain speaking. The violation of the principles of true charity of which they are most flagrant illustrations has been going on for some time. The institution was ostensibly established for the relief of the respectable poor—those who are to be accounted so by their recital of their circumstances, their dress, and general appearance. The dollar-a-month plan has drawn a class (abundantly able, as a rule, to pay a physician) who look down upon the "ordinary" dispensary patient with a "holier than thou" air which the scripturally historical Pharisee himself might envy. The clientele of this institution is drawn without doubt from a less needy class than is that of the German Dispensary, and yet the managers of the latter institution made in our columns some time ago (The Record, June 14, 1885), a statement to the following effect: During the first three months of the current year the cases of one hundred and ninety-two applicants for treatment were investigated by the Charity Organization Society. *Thirty-three per cent.* of this number, it was found, were abundantly able to pay for treatment outside. We characterized this work as the pioneer work in true charity reform, and such it was.

It is straining no point to say that an equal percentage of those applying for treatment at the dispensary of the New York Hospital do not belong to the "poor" class. Yet the institution is doing its work at the expense of the profession. The former takes all the glory; the latter does all the work. If this institution is sincere in its professions, it can no longer desire to see such a state of things continue. How can a remedy be applied? Through the agency we have indicated, by following the praiseworthy example of the managers of the German Dispensary. We know that the debt of the institution chartered by George III. reaches up among the hundred thousands, but we think they might afford one hundred dollars, which would secure the co-operation of the Charity Organization Society for six months. Sincerity would court investigation, but the latter is deferred. The number of persons treated must be as large as possible in order to furnish a justification of the chronic plea of the board of management for financial aid. The "governors" do not wish to be disturbed in their pose before the public as "dispensers of a great charity."

We realize that the dispensation of true charity on a large scale is no easy task. It never has been. So long as the present limitations of human nature obtain it never can be. A certain number of people in this city must rely on charity for medical attendance, but no encouragement should be given to that class who seek to evade their dues to physicians by the faulty management of dispensaries. The latter never ought to be money-making institutions. If the present abuse be not soon checked, it may be that each physician will have his own dispensary, that is, treat people free at his own office during certain hours. In that case the dispensaries would soon find their occupations gone, and their spheres of supposed usefulness properly narrowed.

THE SUPERVISION OF VACCINE COMPANIES.

Small-pox has appeared at Albany, N. Y., Newport, R. I., Peoria, Ill., Newark, N. J., New York City, and at several other places in the United States. Reports of its occurrence at new points are made almost daily. There is a prospect of a wide prevalence of the disease during the coming season, even if it nowhere takes on a markedly epidemic form. There is good reason, therefore, for municipalities and individuals to look sharply after the matter of vaccination, a matter which deserves a great deal more of public attention than it gets. At present, in all large centres, bovine virus in vaccinating is mainly used, and the steadily increasing demand for this has led to the formation of companies who undertake to cultivate and sell it, with a view, primarily, to making money. These companies are not, as a rule, under any official supervision, and are at perfect liberty to disseminate worthless crusts or septic poison among

the people. We learn, as an illustration, that with a lot of bovine virus recently sent to Montreal there were 102 trials and 102 failures, while other specimens have produced badly inflamed arms.

Here, surely, is a most anomalous condition of affairs. It is apparent, at once, that this cultivating and selling of virus should always be under some official supervision. Most States indirectly compel the vaccination of children, and they should, in all justice, see that this vaccination be made with pure and efficient material. Such supervision is exercised in some places, or else the health authorities supply vaccine, as in this city. But the public supervision of vaccine companies is not yet carried out as it should be, although it is a measure most imperatively needed for the security of the people.

PROGRESSIVE DISINTEGRATION.

The past two or three weeks have witnessed a steady and continued disintegration of what is left of the organization of the International Medical Congress. Besides the resignations given in our last issue, we learn that Professor Henry I. Bowditch has refused to accept the Vice-Presidency, and Dr. Henry F. Campbell, late President of the American Medical Association, has declined a similar honor. The resignations are also reported of Dr. E. O. Shakespeare, of Philadelphia, Dr. Henry G. Beyer, U. S. N., Dr. John J. Mason, of Newport. Dr. Jerome S. Kidder and Dr. J. M. Flint, U. S. N.

Dr. R. A. Kinloch, of Charleston, S. C., in withdrawing from the organization, sends an indignant protest against the high-handed methods adopted by the organizing Committee, and its refusal to consider or treat fairly the views of those members desiring to secure harmony rather than have their own way.

Professor Bowditch, in announcing his withdrawal, sends a scathing criticism on the course of the present Committee to the *Boston Medical and Surgical Journal.*

There is a steady growth in the profession of the feeling of indignation against the impudent and wicked conduct of the gentlemen who are so obstinately bound to wreck the Congress. Every week brings new evidences of this and fresh lists of withdrawals. No amount of editorial vituperation in the organ which the profession is now supporting to its own hurt and shame can obscure this fact.

At present the Congress looks to be very much such a thing as Bright's disease, viewed from the standpoint of Dr. Goodheart, viz., "a magnificent scheme of decay."

THE QUARREL OVER RAG DISINFECTION.

For some weeks a lively warfare has been going on between the health officer of this port and the rag importers, as to the question of rag disinfection. The importers have secured the support of a part at least of the daily press, and are frequently posed before the public as martyrs to the obstinacy and dulness, to say no worse, of the health officer.

This gentleman has, however, been right in the course which he has chosen, viz., that of insisting upon the disinfection of rags coming from ports in infected countries. It is both possible and upon record that cholera and small-pox may be transported by rags, which when moist are admirably adapted for the development of cholera germs; and the country has a right to demand that proper precautions be taken, even if importers do not make quite so much money for a time. This is the position taken by a country so alive to its purely commercial interests as Great Britain.

Incidentally the controversy has developed some interesting conclusions on the subject of disinfectants. Several series of experiments have been made to test the destructive power of superheated steam and of the sulphur process on pathogenic germs laid away in bales of rags. It has been shown with apparently a good degree of certainty that these germs can be destroyed by both the steam and the sulphur process. Although such experimental determinations do not furnish perfectly conclusive results, they are tolerably safe guides, and at least the best we can at present get.

THE ACTION OF DRUGS AT A DISTANCE.

At the last meeting at Grenoble of the French Association for the Advancement of Science, MM. H. Bourru and P. Burot, of Rochefort, presented reports of some very curious experiments with certain hystero-epileptic patients. MM. Bourru and Burot are attached, we believe, to the School of Naval Medicine at Rochefort, and their trustworthiness appears to be vouched for by the *Revue bibliographique Universelle.*

The most striking experiments were those illustrating the action of certain medicines at a distance. The hystero-epileptic patient being placed in a chair in the presence of the physicians, a fragment of opium is brought near him; it throws him into a heavy sleep.

Chloral placed at the back of the head caused a light sleep. Various emetics, such as ipecac and apomorphin, being placed near the patient, always, we are told, without his knowledge, caused vomiting.

In the same way alcohol caused a state resembling drunkenness; purgatives produced intestinal contractions; phosphorus produced tremor and hallucinations, etc.

All these phenomena were observed minutely, and sources of error, such as those of voluntary deception, of unconscious or conscious suggestion were believed to be excluded. It is highly probable, however, that the patient, through some of his senses, knew the character of the drug brought near him. The only interesting scientific fact is, therefore, that of the capacity shown to control the organic functions, so that at a certain suggestion diarrhœa, nausea, sweating, palpitations, etc., may be produced.

This capacity was further illustrated by observations in another case. Dr. Mabille, of La Rochelle, had a hystero-epileptic subject whom he mesmerized one evening, saying that at a certain moment he would bleed from the nose. At the hour specified the epistaxis occurred. In later experiments stigmata were brought out upon the arm by "auto-suggestion."

Not Far from the Truth.—Little Boy: Pa, what is a hypophosphite?

Father (busy reading): Oh, don't bother me with your eternal questions. Probably some kind of a crank.

News of the Week.

Arresting Pneumonia and Phthisis by Intra-pulmonary Injections.—M. Lépine, Professor at the Faculty of Medicine, Paris, in a memoir presented to the Académie des Sciences by M. Marey, states that intra-pulmonary injection of solution of bichloride of mercury in pneumonia arrests the progress of the malady and suppresses the rhonchi almost instantaneously. Dr. Truck, a pupil of M. Lépine's, has obtained important results by locally treating cases of tuberculous phthisis according to this method.

The Collodion Treatment of Cholera. — M. Bouley, at a recent meeting of the Académie des Sciences, presented a memoir by M. Arsène Drouhet, of Paris, on the treatment of cholera. He recommends painting the abdomen over with collodion. M. Marius Partrité, who practises in the War Department, appends a few pages to M. Drouhet's pamphlet. Last year he treated a great many cholera patients, and affirms that he effected some unexpected cures with M. Drouhet's remedy. M. Bouley said he should not criticize M. Drouhet's work, but could vouch for his honest intentions and scientific knowledge.

The Preponderance of Female Infants in the West has received further illustration, according to the *St. Paul Globe*, which narrates the following: "The accession of twin girls to the family of the popular County Treasurer, at Fargo, the past week, calls attention to the general fact that from three-fourths to four-fifths of the births in Dakota at present are of the female sex. Apprehension is felt that the thing is being overdone in that direction. Some attribute it in some undefined, mysterious, psychological way to the woman rights' furor and the romantic and absurdly exaggerated pictures drawn by Colonel Donan of the scarcity of females in Dakota."

Another New Medical College.—It is hard to see what possible need Florida has for a medical college. We have received, however, the announcement of one which has recently been organized in Tallahassee. Curiously enough it starts full-fledged with an Emeritus Professor, who necessarily has never been anything but "emeritus."

It is interesting to learn that there is a National Association of Undertakers, which held its annual meeting in Philadelphia last week, and voted not to offer a $1,000 prize for the corpse that had been best embalmed for sixty days.

"Epidemic" is said to be the title of a new journal just started in the South. It is expected that everybody will take it.

Death of Dr. William H. Coggeshall.—We regret to announce the very sudden and untimely death of Dr. William H. Coggeshall, Associate Editor of the *Virginia Medical Monthly*. Dr. Coggeshall was a gentleman of more than ordinary promise, and had already attained an enviable position in medicine and as a journalist.

Honoring an American Physician.— Under the title, "An English Welcome to Dr. Parrish," the *Medical Press and Circular* says: "Dr. Parrish, the eminent American apostle of temperance having visited this country with a view to inspecting the working arrangements of the Homes founded here for the treatment of confirmed inebriates, the occasion was seized to offer him a general welcome from the prominent temperance organizations in Great Britain. To this end the President and Council of the Society for the Study and Cure of Inebriety issued a large number of invitations to the Dalrymple Home at Rickmansworth, and on Saturday, the 19th inst., a special train conveyed the party to the Home, where, after lunch, a meeting was held in the new Concert Hall. The chair was taken by Dr. Norman Kerr, who, in an eloquent speech, welcomed Dr. Parrish to England. Among the subsequent speakers were Dr. Langdon Down, Dr. Danforth Thomas, Mrs. Lucas, and the Rev. Mr. Murphy."

The Total Number of Physicians in the world is estimated to be 190,000.

Newport and Small-pox.—According to a report furnished by the Secretary of the Newport Medical Society, Dr. W. Thornton Parker, the public vaccinators of the city, Drs. Barker and Sears, in a house-to-house vaccination, vaccinated 521, and were refused permission to vaccinate 707 persons. So that there is a large proportion of unprotected persons yet in that city. A great service would be done, according to the Secretary, if the teachers and pastors of private and parochial schools would insist on the vaccination of their pupils.

The Attempt of Anthony Comstock to obtain judgment against a number of New York druggists for selling an article prohibited by the Penal Code has caused considerable stir among that fraternity. We trust that Mr. Comstock will succeed in stopping the India-rubber branch of the drug business.

"The Medical Press of Western New York" is the title of a new monthly medical journal edited by Dr. Rosswell Park. It aims to represent the interests of the profession of Western New York and vicinity. In these progressive days it is perfectly natural that where there are two medical colleges there should be two journals. Both of our Buffalo contemporaries are interesting journals.

The Machine for Static Electricity: A Question of Priority.—Mr. D. Rosseau, of this city, writes: "I notice in your issue of the 17th inst. the description, by Ambrose L. Ranney, M.D., of a so-called new apparatus for generating static electricity. I am very much surprised at the similarity to the Induction Holtz Machine manufactured by me for nearly two years. With the exception of the rubber, the principle of the machine was discovered by Holtz, but the new construction, as described by Dr. Ranney, was devised by me, with the help of Charles Van Brunt and H. D. Hall. The first one I sold for medical use was to Dr. M. A. Pallen, in September, 1884; and one to A. C. Hutchinson, President of Morgan's Louisiana & Texas Railroad, also in the fall of 1884; and one to Dr. T. Hamilton Burck, December 18, 1884.'"

American Academy of Medicine.—The ninth annual meeting of the American Academy of Medicine will be held at the New York Academy of Medicine, No. 12 West Thirty-first Street, New York, on Wednesday and Thursday, October 28 and 29, 1885. Interesting papers

will be read by Drs. Sibbet, of Carlisle, Pa.; McIntire, Jr., of Easton, Pa.; Marcy, of Boston, Mass.; E. H. M. Sell, of New York; Turner, of U. S. Navy; Dunglison and Lee, of Philadelphia; Nelson, of Cambridge, Mass.; Cushing, of Boston, Mass.; Jackson, of Philadelphia; Kelly, of Utica, N. Y.; and Bush, of Wilmington, Del. The Address will be delivered at eight o'clock on Wednesday evening, by Albert L. Gihon, A.M., M.D., United States Navy, President, on "What is Medicine?" The annual collation will take place on Wednesday evening, October 28th, immediately after the President's Address.

How not to Remove Dampness in the Static Electric Machine.—A correspondent sends the following reasonable statement: "The device resorted to by Dr. Ranney for removing dampness from within the case of his static electric machine (see The Medical Record, October 17th, p. 447) will amaze his readers. Burning an alcohol lamp within the case is equivalent to filling the latter with carbonic acid and the *vapor of water*, which are the well-known products of the combustion of alcohol."

Vaccination in Montreal.—Dr. L. D. Mignault, Professor of Anatomy, Victoria College of Montreal, writes: "I have read with interest your items upon our epidemic, and I am pleased to see that your information has been in general gathered from reliable sources. It is always a satisfaction to see the medical journals of a distant city giving full and truthful details of all that passes around us. At the same time I am sure that you will allow me to modify a statement which affects the reputation of a large medical school, and which would be a great injustice to its members in general. While admitting that we have upon our staff the 'influential man' referred to, allow me to state that he is not at present engaged in lecturing, having retired nearly a year ago on account of his age and infirmities. He, moreover, never had much scope to ventilate his views, as he held the chair of Materia Medica. We have among our body the President of the Provincial Board of Health, and several others who are earnest and active workers in the cause of vaccination. Moreover, our school published over a month ago a resolution in favor of vaccination which I enclose, and finally, nearly all our students have been revaccinated since the outbreak."

The Therapeutics of Hay Fever.—Dr. F. A. Burrall, of this city, writes: "In Dr. Beverley Robinson's article, in The Record of October 17th, on 'The Therapeutics of Hay Fever (so called),' he refers to the effect of cocaine in producing 'secondary occlusion of the nasal passages, due, as I believe, to a paralytic condition of the turbinated structures caused by its action.' This observation confirms what I have observed in two instances, where I had given cocaine hypodermatically for the relief of what is usually termed nervousness. There was at first an agreeable calmative effect, which was followed, after one or two hours' interval, by what seemed to be not severe cerebral congestion. I think the expression which the patient used concerning the effect was that the 'whole thing rushed back upon him.' In this case there was probably a tonic contraction of the vascular coats, followed by sudden dilatation. The patient found the sensation rather disagreeable. It must be, judging from the published reports, that cocaine relieves some cases of hay fever very much, but it is not a panacea, as I have found from experience. I have recently, however, had an excellent result from its use in the case of a patient suffering from nasal catarrh, who had had frontal headache for about eight years. I prescribed a four per cent. solution, and told him to pass a brush dipped in the fluid well up into the nostrils whenever the pain troubled him. The relief obtained has been so great that the patient expressed his estimate of cocaine by saying that he considered it as 'worth its weight in gold.'"

Texas Physicians and Surgeons are working hard and ambitiously for the credit of the profession of their State. One interesting work, of which the first instalment was presented at the last meeting of the State Society, consists in a compilation of the surgical records since the year of annexation. This compilation has been brought down to 1877, and includes the notes of 1,837 operations, carefully classified. There will be an annual report of work of Texas surgeons, which will eventually bring the record to date.

Medical Affairs in Buffalo appear to be in a somewhat mixed state. There is a great deal of partisan feeling with regard to the two medical colleges. Certain gentlemen have also charged the medical staff connected with a large hospital with concealing deaths in making their annual report. The matter was unwisely brought before the Buffalo Medical and Surgical Association, and a great deal of bitter controversy resulted, to the great detriment of the interests of the Society. More brotherly love and fewer medical colleges are needed in Buffalo.

Medical Portrait Galleries.—The ordinary portraits of eminent physicians which appear in serial medical literature are apt to give painful impressions of artistic insufficiency and of wide departure from a high standard of personal loveliness. We are obliged to confess that we have seen several specimens which would furnish very admirable illustrations of unsuccessful pugilism and debauched manhood. It is with great pleasure that we congratulate the *Virginia Medical Monthly* on producing a finely etched portrait that has real artistic qualities. We commend it as a sample to those of our contemporaries who have contemplated conferring the questionable boon of a lithographed or wood-cut immortality upon their distinguished confrères.

A Minnesota Reformer suggests a tax on male celibacy, making forty years the limit of exemption. He proposes that the proceeds be directly devoted to the support of foundlings.

Professor Bamberger.—Great sympathy is felt for Professor Bamberger, of Vienna, who was accidentally killed while making the ascent of a mountain. Professor Bamberger had just been elected Rector of the University of Vienna, but felt obliged to decline the high honor.

A New Anæsthetic Mixture, composed of dimethyl acetal ($C_4H_{10}O_2$) two volumes, and chloroform one volume, has been used at the Strassburg surgical winter, and Dr. F. Fisher reports fifty cases illustrating its action. It is not followed by vomiting, and it stimulates the heart. It is especially useful in children, or in cases where there is heart or renal disease.

The Montreal Small-pox Epidemic does not decline in violence, and will not be likely to do so until all the material has been used up. The authorities, now that it is too late, are beginning to make strenuous efforts to limit the spread of the disease. On the 20th inst. the local Board of Health passed a resolution advising the closing for a month of all theatres, churches, skating-rinks, and all places of public resort. Such a measure would involve a great sacrifice for a doubtful return, and will hardly be adopted. Montreal must attempt a complete and systematic house-to-house vaccination with good virus. This, with thorough cleanliness and proper quarantining of cases, would have checked the epidemic at first, and may help to do it now.

A Misapprehension.—When the father of a family has been successfully vaccinated, says a Montreal paper, it is frequently his custom to ask for a certificate for the whole household, vaccinated or not. A good deal of trouble is caused the public vaccinators from this cause, paterfamilias often needing a good deal of argument to convince him.

Dr. William Workman, for more than forty years one of the leading physicians of Worcester County, Mass., died at his residence in Worcester on October 17th. He was born in Coleraine, Mass., in 1798, and was graduated at the Harvard Medical School in 1825. He practised for ten years in Shrewsbury. Dr. Workman joined the Massachusetts Medical Society in 1831. He removed to Worcester in 1835, and continued in active practice in that city until 1869, when he retired. He held numerous positions of public and private trust, and for ten years was a trustee of the Lunatic Hospital in Worcester.

Preparing for Hospital Sunday.—The Hospital Saturday and Sunday Association held its first meeting since January on Monday last. General Agent Frederick F. Cook said in his report that the outlook for the ensuing year was most encouraging. Circulars requesting contributions are to be placed at the disposal of merchants and manufacturers throughout the city, and all lines of trade are to be thoroughly canvassed. Benevolent lodges and all suburban churches within fifty miles of the city will be invited to swell the collections.

The Late Dr. George Alt-Müller.—Dr. George Alt-Müller, who died at Glen Cove, L. I., October 13th, was born in Schwartau, Germany, October 4, 1808. In 1832 he matriculated at the Frederick William University. Among his professors are included the names, Von Graefe, Schlemm, Rose, Link, Ehrenberg, and Mitscherlich. In May, 1835, he received his degree as Doctor Medicinæ et Chirurgiæ from the Christian Albert University, Berlin. His thesis, "Non nulla de Epilepsia," recorded original investigations, and conclusions which have been amply verified. He began the practice of medicine in Lübeck, where he was the colleague of Leopold in hospital work for several years. In 1848 he became a citizen of the United States, and two years later settled in Jericho, L. I. His practice grew rapidly, and extended over several townships, until in 1860, in response to the repeated calls of many friends, he removed to Glen Cove. He was a member of the Queen's County Medical Society, and was elected its President in 1867. Though actively engaged in the practice of his profession for many years, Dr. Alt-Müller's life was essentially that of the student; he was learned not only in his profession, but in the allied sciences. He was especially interested in botany, an accomplished microscopist and electrician. With his scientific attainments he united a rare charity and gentleness of speech and manner, and enjoyed the esteem and confidence of a large clientage. He died full of years and crowned with benedictions.

The Medical Faculty of Johns Hopkins University.—Five of the chairs in the future medical department of Johns Hopkins University have now been filled, as follows: Dr. H. Newell Martin, Professor of Biology; Dr. Ira Remsen, Professor of Chemistry; Dr. William H. Welch, Professor of Pathology; and Dr. John S. Billings, U.S.A., Professor of Public Hygiene; Dr. Matthew Hay, of Edinburgh, Professor of Pharmacology. So far, the chairs have been most creditably filled.

Cocaine in Hay Fever.—Dr. J. W. Stickler, of Orange, N. J., in correcting an error in an article of his on this subject in the October 17th issue, writes: "I wish to say that Allen's cocaine tablets are worthless as a remedy for 'hay fever.' I say this because they were recommended as a good 'article,' but careful trial failed to show any cocaine effect."

Reviews and Notices.

The Management of Labor and of the Lying-in Period. By Henry G. Landis, A.M., M.D., Professor of Obstetrics in Starling Medical College, etc. 8vo, pp. 334. Philadelphia: Lea Brothers & Co. 1885.

Obstetrical treatises, says the author in his preface, are usually written for both students and practitioners. If they are particularly adapted to either one of the two—alone—they are not of service to the other. "The aim of this book is to serve as a guide to practice, divested of all superfluous or irrelevant details." Its teachings are in the highest degree orthodox, but we fail to find in them any new information. In fact, it rather seems to us as if the spirit had said to the author "Write a book," and had been so unkind as to forget to name the reasons for so doing. It may save, however, some trouble in looking through more bulky volumes for the facts one is in search of. Its literary style is commendable; its typographical appearance is excellent.

Poisons; their Effects and Detection. A Manual for the Use of Analytical Chemists and Experts. With an Introductory Essay on the Growth of Modern Toxicology. By Alexander Wynter Blyth, M.R.C.S., F.C.S., etc. With Tables and Illustrations. Vol. II. New York: William Wood & Co. 1885. Wood's Library of Standard Medical Authors.

We have already spoken in terms of warm praise of the character of this work. Giving as it does a complete history of poisons in all but their strictly medico-legal relations, Mr. Blyth's treatise cannot but be of great practical service in many of the emergencies of the general practitioner. The present volume completes the vegetable and animal poisons and takes up the subject of metallic poisons. Two appendices—on the examination of the blood and on treatment of cases of poisoning—conclude the work.

Tracheotomy in Laryngeal Diphtheria: After-treatment and Complications. By Robert William Parker. Second Edition, pp. 124. London: H. K. Lewis. 1885.

This monograph has for its avowed purpose, first, "to advocate the utility and importance of local treatment in cases of laryngeal diphtheria (membranous croup); and second, to give, for the use of house surgeons and practitioners, short but detailed instructions as to how such treatment may be easily carried out."

The author justly recognizes that the after-care, as indeed is the case in most operations, is often more than two-thirds of the battle, and his concise and explicit directions will be appreciated by those who have sought in vain in more extensive works information in these particulars.

Inebriism: A Pathological and Psychological Study. By T. L. Wright, M.D. Pp. 222. Columbus, O.: Wm. G. Hubbard. 1885.

Dr. Wright has set himself the task of interpreting inebriety according to the most recent ideas of nervous force and its physical basis. It is a trifle, perhaps, but one cannot help stumbling over the coined word, *inebriism* which is used for a title, and suspect the author of straining for effect in substituting it for the legitimate word *inebriety*.

Anecdotes and cases illustrate the author's ideas and serve to clinch his arguments. The general reader, perhaps more than the medical, will find it interesting reading.

On Renal and Urinary Affections. By W. Howship Dickinson, M.D. Cantab., F.R.C.P. Pp. 343. New York: William Wood & Company. 1885. Library of Standard Medical Authors.

Dr. Dickinson's present work is supplementary to that on "Albuminuria" (published in Wood's Library in 1881). Together these volumes form a comprehensive treatise on renal affections, which must take a solid and enduring place in medical literature. Dr. Dickinson is one of the most satisfactory of medical authors. To a mind eminently practical in turn, he adds a large clinical experience, a thorough knowledge of pathology, and a mature and conservative judgment. He has few theories to advance, but prefers rather to present clinical facts as they are, and abides finally by the judgment of experience rather than scientific deduction. His present work takes up a large variety of topics: Abscess of the kidney, pyelitis, perinephritis, thrombosis and embolism, renal tumors, malignant disease of the kidney, tubercle, hydro- and pyo-nephrosis, renal cysts, renal calculi, movable kidney, urinary paraplegia, diseases of the ureters, renal parasites, chyluria, hæmaturia, phosphaturia, albuminuria, suppression. Among the most attractive features of this work are the tables showing the varieties of epithelium from the healthy urinary tract, the cuts illustrating the relations of renal tumors, and the tables showing the relation of albuminuria to other than renal disorders. The author gives a table showing the not very promising results of the excision of the kidney for malignant tumors. Of eleven cases operated upon only three recovered. Tables showing the results of nephrectomy and renal lithotomy are also given.

Diseases of the Heart and Thoracic Aorta. By Byron Bramwell, M.D., F.R.C.P.E., With Three Hundred and Seventeen illustrations. Pp. 773. New York: D. Appleton & Co. 1884.

Dr. Bramwell's treatise on "Diseases of the Spinal Cord" showed him to be a writer with tremendous powers of absorption, systemization, and illustration. Ability in all these directions is abundantly shown in the present large volume. We are not quite so profusely loaded with pictures, cross-sections, and colored lithographs, but there is sufficient of them, and the author shows himself to be a good pathologist and to have had a wide clinical experience on the subject of which he writes. The present work is evidently the result of long and patient labor and accumulation of material.

The author begins his treatise by an account of the anatomy and physiology of the heart. The physiological descriptions are based largely upon the views of Gaskill, and represent the latest theories regarding cardiac innervation. Dr. Bramwell gives us a taste here, also, of his skill in diagrammatic representation.

Proceeding with his usual system, the author then takes up the subject of the general pathology of the heart. This method of dealing, first generally and then specially with a subject is an attractive one to writers, but it must be confessed that it often leads to diffuseness, repetition, and ultra-refinements in classification.

The important subject of the clinical investigation of cases receives careful attention. The author gives a synoptical table for use as a guide in case-taking. A discussion of the symptoms as related to age, sex, occupation, with descriptions of the pathology of different symptoms, follows. The mechanism of Cheyne-Stokes respiration is discussed, and some interesting illustrative diagrams are given. We think that the author's explanation of this curious phenomenon is the most rational, as it is the most simple one.

A reader will naturally turn with interest to the chapters on the physical examination of the heart and organs of circulation. The author deals with this part of his subject with great minuteness. We have here given us, in fact, a very complete work on physical diagnosis as regards the heart. It is somewhat discouraging, however, to read so many opinions and theories bearing upon certain parts of this subject. The mechanism of murmurs, their reduplications, combinations, and significance are still evidently matters largely of speculation, and he must be a patient and enthusiastic student who will try to follow the why and wherefore of each different teacher's opinion. In his descriptions of the use of the sphygmograph, the author gives an account of the various tracings in disease and health, and shows us their helpfulness in the study of dicrotism, vascular tension, variations in pulse, volume, rhythm, etc. We miss, however, a comprehensive and practical summary of the uses of this much-discussed instrument.

The various chapters which take up the special diseases of the heart and its membranes cannot be discussed fully here. The same carefulness in method and preciseness of detail are exhibited as in the first half of the book. Numerous tables for differential diagnosis are given. We may mention briefly some of Dr. Bramwell's views upon the more interesting practical points. He believes that the salicylates in acute rheumatism tend to prevent heart complications. In dangerous pericardial effusion the author recommends puncture, without, as it seems, having had any personal experience in the matter. In the treatment of chronic mitral incompetence, the author places much confidence in arsenic. Caffein and glonoin are recommended in cardiac venous engorgement. The treatment for mitral stenosis is identical with that for mitral incompetency. In aortic regurgitation the prognosis is more favorable and life more comfortable, barring accident, than in mitral lesions. Arsenic, iron, iodide of potash, and digitalis are to be used in treatment. The author does not give a satisfactory account of the acute cardiac dilatation toward which so much attention has been directed of late years.

Dr. Bramwell has written a work on the diseases of the heart which is easily first among treatises on this subject. While not such easy reading as some of the older books, it is an indispensable work for study and reference.

The Universal Benefactor is the comprehensively philanthropic title of a new periodical devoted to the subject of preventing adulterations in food, drugs, etc.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, September 23, 1885.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

RECURRENT EPITHELIOMA OF THE PENIS.

DR. WILLIAM PERRY WATSON presented a specimen, and also the patient from whom it was removed, a laborer, forty-nine years of age, born in this country. The family history was good. The patient had always been in good health, barring accidents. Dr. Watson was called to see him about two years ago, at which time he had a profuse hemorrhage from the penis. The glans and a large portion of the body of the penis were in a state of ulcerative degeneration, resembling very much an epithelioma. The question arose, Was it an epithelioma or a case of simple ulcerative destruction of tissue? At any rate, the indications were to remove the diseased tissue, for the patient was reduced from repeated attacks of hemorrhage. It was learned that he had always suffered from a tight phimosis, interfering with the free escape of urine, and causing ballooning of the foreskin during micturition. In 1865, while sitting at table, a fork was thrown at him, and as he receded from the table one of the tines pierced his clothing and wounded the dorsum of the glans penis. Considerable hemorrhage followed, but not sufficient to cause him to call a physician. Soon afterward he was admitted to Bellevue Hospital, where he said Dr. Hamilton amputated the foreskin and indurated tissue, but did not touch the head of the organ. It was probable the induration, of which the patient spoke as having been removed by Dr. Hamilton, was simply a clot of coagulated blood. After this he had no trouble for about six months, when he noticed on the under surface of the penis, near the frænum, a small growth of bright red color, which looked like a wart. This continued to grow, and, being constantly irritated, he had it removed about six months later. Another six months passed, when, on the base of the wart, an ulcerative process set up and extended to the glans, and during the year prior to Dr. Watson's attendance, had caused hemorrhage sufficiently profuse to reduce his strength and necessitate amputation. There was no enlargement of the inguinal glands. Circular amputation was performed through healthy tissue; the urethra was slit up and stitched to the skin. The man made a rapid recovery, going out on the ninth day. His condition had since remained good; there was still no enlargement of the inguinal glands, but the epitrochlear glands were slightly increased in size. There was no history of specific trouble.

THE PRESIDENT said the fact that the man had had phimosis was worthy of attention. During the past eighteen months he had seen four cases of epithelioma of the penis, in three of which he performed amputation, and the nature of the disease was verified by microscopical examination, and in all four cases there had been a history of phimosis. Since then he had asked a number of surgeons who had performed this operation what had been their experience, and he had not learned of a single case of carcinoma of the penis in which there had not been phimosis. This was certainly another indication for circumcision.

DR. WATSON added that he presented this case as illustrating the necessity for relief of phimosis in children, as the epithelioma undoubtedly resulted from that condition.

VERMIFORM APPENDIX, SIX INCHES LONG, ATTACHED TO THE HEPATIC FLEXURE OF THE COLON.

DR. LOUIS WALDSTEIN presented an unusually long vermiform appendix (sixteen centimetres), found in dissecting a body at the German Hospital. Another point of interest was the fact that instead of the process lying in its usual position, pointing downward in the pelvis, it extended upward toward the hepatic flexure of the colon, to which it was attached. Its position was parallel to the long axis of the body. He had seen several similar but somewhat shorter specimens.

BILIARY AND RENAL CALCULI IN THE SAME PATIENT.

DR. WALDSTEIN also presented a renal calculus, composed of urates, which was interesting in connection with the clinical history. Mr. S—— was seen by him last April, when he was suffering from severe pain in the abdomen. On examination the greatest tenderness was elicited on pressure over and a little to the right of the epigastrium, from there radiating over the entire abdomen. There was also slight icterus of the conjunctivæ and integument. Further observation of the case, with examination of the fæces, led to the diagnosis of biliary calculus, with the occasional passage of a stone through the duct, causing the usual paroxysmal pain. The patient was put under the Carlsbad treatment and steadily improved. It was learned that he had been suffering from gastric trouble for eleven or twelve years, and in such cases, Dr. Waldstein remarked, there often developed after some time trouble with the biliary secretion, and we find small biliary concretions in the fæces. In this case he found large numbers of small stones in the fecal discharges. One night last June Dr. W. was called to see the patient in another attack, but he found the picture entirely changed; instead of locating the centre of pain in the epigastrium, it started from the right lumbar region and extended downward, and was traceable along the ureter and right leg. There was diffuse pain over the abdomen. The gentleman told him that while micturating he felt a peculiar sensation at the glans penis, and also a sensation of dizziness, and saw occasionally muscæ volitantes. A fact which struck Dr. W. as peculiar was that all the attacks of pain were associated with a tingling in the tips of the fingers of both hands. The conclusion was reached that there was some deposit in the pelvis of the kidney or high up in the ureter. Improvement took place under treatment, and a week ago the patient sent him the stone presented, which had been passed with his urine. Dr. W. presented the case without further comment than that here was a person who had suffered from digestive derangement for a number of years, and who finally developed both biliary and renal concretions.

THE PRESIDENT asked, regarding the first specimen, how firm was the attachment of the appendix?

DR. WALDSTEIN replied that its attachment to the colon was firm, but that it could be separated. He received the impression that there had been some local peritonitis, that there was some dislocation of the colon downward, during which the adhesion of the appendix took place; the colon afterward assuming its natural position, carried the appendix with it.

THE PRESIDENT recalled having seen a greatly distended vermiform appendix when in Bellevue Hospital. He believed it was now in Wood's Museum. He had not seen any as long as the specimen presented.

The Society went into executive session.

READY-MADE ILLUSTRATIONS. — Every medical man who records his cases either for publication or for private use, will appreciate the clinical figures published by Danielsson & Co., of London. These are outline illustrations of various portions of the body and of the different organs upon which the location of the lesions can be marked. Each diagram has a gummed back, so that it can be readily pasted in the case-book. The illustrations of various sections of the brain and spinal cord are especially worthy of note, and cannot but be very useful to every student of cerebral pathology. The labors of hospital internes would be much simplified, and the records kept by them rendered much more lucid, by a free use of these anatomical diagrams.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 15, 1885.

A. JACOBI, M.D., PRESIDENT, IN THE CHAIR.

THE ACADEMY FREE FROM DEBT.

DR. F. A. CASTLE, Treasurer of the Board of Trustees, reported that the final payment on the original mortgage of ten thousand dollars had been made, leaving the Academy entirely free from debt.

SECTIONS IN THE ACADEMY.

DR. A. B. JUDSON, Secretary, reported that the *Surgical Section* had organized with Dr. Stephen Smith, Chairman, and that the stated meetings would be held on the *second Monday* evening in each month, at the Academy, beginning at eight o'clock.

DR. A. S. HUNTER, Chairman, announced that stated meetings of the *Section in Obstetrics and Diseases of Women and Children*, would be held on the *fourth Thursday* evening of each month, at the Academy, beginning at eight o'clock.

DR. E. DARWIN HUDSON, JR., Secretary, gave notice that the stated meetings of the *Section in Practical Medicine* would be held on the *third Tuesday* evening of each month, at the Academy, beginning at eight o'clock.

The stated meetings of the *Section in Neurology* will be held on the *second Friday* evening of each month, at the Academy, beginning at eight o'clock; Dr. L. Putzel, Chairman.

The *Section in Ophthalmology* will be organized October 19th, the *third Monday* in the month.

DR. STEPHEN SMITH then read a paper entitled

THE COMPARATIVE RESULTS OF SURGICAL PRACTICE IN BELLEVUE HOSPITAL.

It was published in THE RECORD for October 17, 1885.

DR. A. C. POST was invited to open the discussion, and remarked that he had been very much interested in the lucid account, given by the author of the paper, of the marked improvement in the more modern surgery of Bellevue Hospital. He was prepared to sanction what Dr. Smith had said with regard to cleanliness, but thought there was still room for doubt as to how much antiseptics had contributed to the success obtained in surgery at the present time. Thorough cleanliness is in all respects very important, and the seclusion of the wound from external influences is also an important item in its treatment. His doubt was based upon the experience of European operators, especially Lawson Tait and Thomas Keith, who had been most successful in their laparotomies, and who regard antiseptics as not only useless but pernicious; that their use adds a small percentage to the fatality of this operation.

Dr. Post, however, was disposed to believe in the efficacy of antiseptic dressings in addition to cleanliness. There was no doubt that great improvement had been made within the last few years in the surgical treatment of wounds, but whether the success was due to antiseptics more than to cleanliness might still be an unanswered question.

DR. W. GILL WYLIE had nothing special to add to what had been stated in the paper. It might be remarked, however, that previous to three or four years ago, ovariotomies were not performed in Bellevue Hospital. The introduction of antiseptics had done good, and although it was probable that their use had been at times carried too far, still, if the methods of Keith and Tait were followed out, it would be found that if they did not use antiseptics they applied, besides cleanliness, such dressings as insured protection against whatever influences or agents might be in the air, and really employed a Lister dressing. Dr. Wylie used antiseptics as a supplement to cleanliness.

Many of the reasons formerly given why Bellevue Hospital should be removed had been rendered powerless by the introduction of cleanliness and antiseptic dressings, but none of us knew what surgical cleanliness was until Lister told us.

DR. F. V. WHITE referred to one successful amputation of the thigh while he was interne in Bellevue. He also asked Dr. Smith whether or not bony union took place in the cases in which the fragments of fractured patella were wired together.

DR. W. M. CARPENTER mentioned the notable disappearance of specimens of surgical kidney, and other grave lesions following surgical operations, during the last few years of his service as Assistant Curator to the Hospital.

DR. SMITH thought it probable that antiseptic surgery had led to extreme cleanliness. He also believed that those who were ridiculing antiseptics were doing great harm, and considered that the care with which Mr. Tait prepared his sponges showed that he did not operate as used to be done in Bellevue. It was very probable that Tait secured thorough cleanliness by means of hot water and other measures, and the employment of experts who devoted themselves to his work.

With regard to the kind of union after fracture of the patella, Dr. Smith had wired the fragments together in *seven* cases, and the result had seemed to be union by bone.

THE ERNST KRACKOWIZER PRIZE-ESSAY FUND.

The object for which a society of laymen and medical gentlemen was organized having ceased to exist, there remained the sum of $1,155, which, through Mr. Paul Baluff, Chairman, and Dr. Herman Guleke, Secretary, was presented to the Academy, with the special provision that the accumulated interest therefrom should be available every third year as an award for an essay, the standard and merit of which should be determined by a committee composed of the Presidents of the Academy, of Bellevue Hospital Medical College, of the Medical Department of the University of the City of New York, and of the College of Physicians and Surgeons, Medical Department of Columbia College, unless the Academy should decide otherwise. This sum shall be registered on the property returns of the Academy as the "Ernst Krackowizer Prize Fund."

On motion by DR. F. V. WHITE, and seconded by DR. F. A. CASTLE, the presentation was accepted with the thanks of the Academy, and referred to the Council with power.

DR. STEPHEN SMITH moved that a committee be appointed by the President, and that the President and the Recording Secretary of the Academy be the Chairman and Secretary of the Committee, to report at some future date their conclusions with reference to amendments to the Constitution and by-laws looking toward more complete work in the sections. Carried, and the President was empowered to enlarge the committee to make it correspond with the number of sections.

The Academy then adjourned.

TUBERCULOSIS AND VACCINATION.—Dr. Acker states (*Deutsche Medicinal Zeitung*, No. 29, 1885) that vaccine lymph taken from tuberculous individuals is entirely free from bacilli, and that consequently vaccination with pure lymph unmixed with blood cannot transmit tuberculosis. And the author even asserts that did the lymph contain tubercle bacilli there would be no danger of inoculation, for recent experiments have shown that tuberculosis cannot become developed in superficial cutaneous wounds.

A RUSSIAN CHOLERA COMMISSION.—The Russian Government has sent three physicians to Spain to study the cholera, and Ferrán's method of preventive inoculation. The commission is composed of Drs. Manassein, Rapcheffski, and Kurloff.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE PROVINCIAL SCHOOLS OF MEDICINE—MR. JONATHAN HUTCHINSON AT LEEDS—HIS VIEWS OF EDUCATION—OF KNOWLEDGE, WISDOM, HEREDITY, ETC.—SHEFFIELD SCHOOL AND FIRTH COLLEGE—MR. BRADLEY AT LIVERPOOL—"STUDY OF UNIVERSALITY"—THE SHADOW OF THE DEATH OF MR. WALKER—THE DEATH OF DR. JAMES RUSSELL—THE PRESENTATION ON HIS DEATH-BED—THE LATE DR. S. MONCKTON.

LONDON, October 10, 1885.

LAST week I gave you some notes about the opening of the London schools. I may supplement them by some remarks as to the same event in the provinces, for in England the provincial schools also open on October 1st, although in Scotland and Ireland they remain in vacation for another month.

As almost a London event I may put the Leeds school first, for there my versatile friend, Mr. Jonathan Hutchinson, F.R.S., delivered the introductory, and took for his subject "The Uses of Knowledge." Of course he was listened to with attention—he always is, mainly, perhaps, because he always has something to say. Then he is a Yorkshireman, and was therefore at home among his brethren, on a visit, too, after years of metropolitan success, and Yorkshire is hospitable and reverences success. Mr. Hutchinson's success has been steady as well as rapid. Few of our London consultants have advanced with more even, constant steps, and all along with the good wishes of his brethren. His secret many would like to learn, though it is no secret; he has merely done what was before him with steadfast, earnest purpose, without show or any attempt at brilliancy. He has proved himself prepared for whatever duty might come to him, and capable of advising on almost any case. He has cultivated more than one specialty—indeed so many, that he is a sort of general specialist, a thoroughly "good all-round man," with extra points in several departments. This is largely the result of industry. The mere reading he must have done would alarm many a man who cannot be called idle. His solidity is well exemplified in the operating-room. He never does anything to excite attention, still less enthusiasm, never seeks the applause of colleagues or students, but does his work cautiously, yet well, as if all he thought of was to do what was necessary for the patient with the least fuss or flurry. Some of our younger surgeons, some even brought up at his feet, would do well to copy him in this.

But about his address—well, according to the Leeds papers, I judge it capable of exciting discussion, even opposition. I could object to much myself, but can keep my objections to talk over with him—at any rate the chief. He urged the limitation of our memory, and held that it would be good to remember this: We can only store away, he said, a certain quantity, and the pressing of more in must force something out. Is the mind, then, like a travelling trunk, its capacity fixed beforehand? The doctrine would certainly tend to lessen the burdens of the student. Surely, however, it is expansible, or what a capacity it must naturally present—as we see in Mr. Hutchinson's own case! Whatever we do, he says, we soon reach the limit, and must then choose what to retain and what to commit to oblivion. Hear this, you examining boards, that are always adding something to the subjects which men are to cram up.

What to choose, then? Special things are to most of us in the way of duty, he says; beyond these is a range for choice. So a surgeon must ever retain what is essential for practice. That is first. The range of other knowledge acquired may make him a well-informed man.

But the uses of knowledge—and here, if accurately reported, he became a little less lucid than usual, though I have previously heard some mystical remarks of this kind from his lips. The noblest faculty, he says, is love, and this is not an abstract quality, springing up causelessly in our hearts, but the result of hereditarily transmitted faculties, by which we take cognizance of beauty. No doubt the young men who heard this thought they learned something. Let them tell it to their sweethearts, and I doubt if it produces more impression than a statement of the chemical composition of tears, when offered to show the futility of grief.

And Mr. H.'s favorite notion of heredity is applied also to wisdom, which, he says, cannot exist apart from the matured results of hereditarily transmitted knowledge; and to cap this handy assertion, he added, "No ignorant person, born of ignorant predecessors, can possibly be wise." I fancy few communities will indorse this doctrine. Heredity may be a factor in many things, but is it not a proverb that the sons and grandsons of wise men seldom evince a tithe of their wisdom?

Descending to matters of less importance, the kind of knowledge affecting education, Mr. Hutchinson would banish Greek and Latin from the boys' schools, and deliver our girls from the attempt to learn French, and some very smart things he said on this subject. Geology and poetry are better than French and German for an English boy or girl to study, and far better for a man or woman to remember; and as memory is limited, why burden it with languages, which are likely to be of little use? Audacious as this view will seem to many, there is something to be said for it in these days, when knowledge is so multiplied that the text-books of a student are more extensive than the library of the ancient sage.

Mr. Hutchinson would, as a counterpart to the dismissal of philology in order to make room for science, have all technical terms reduced to English, and compel the writers to find equivalents which every English reader could understand for the strange syllables which meet them on every page of botanical or geological manuals. He thinks an enterprising publisher who produced such books would succeed. Let us hope the hint will be taken, for why should the language of flowers be the most jaw-breaking combination of unnaturally conjoined syllables? But how can such a thing ever come if wisdom is only the result of hereditarily transmitted knowledge? Gamopetalous, monœcious, syncarpous, and so on, do not approach more closely to English than when first coined, and it is difficult to believe that generations of cacophonous syllables will hereditarily transmit euphonious language.

At Sheffield, Mr. Pye-Smith congratulated his audience on the prospect of incorporating the medical school with Firth College, which is fully equipped in all the departments of science. About £2,000 is required for new buildings and ought at once to be forthcoming, for Sheffield manufacturers are many of them rich, and examples of liberality have not been wanting among them. He appealed for public support to the hospitals, and deprecated the objections often made to *post-mortem* examinations, which were of so much value in promoting knowledge useful to the living. He also offered the students good advice in the pursuit of their work, and some remarks to stimulate their devotion to duty.

At Liverpool, Professor Bradley delivered the address, and took for his subject "The Study of Universality," as Bacon in his day called it when he complained of its neglect. Now that his college was formally associated with the new Victoria University, this subject was appropriate and would commend itself to many. Mr. Bradley would apparently like to see students more or less associated with other Faculties in the University than medicine, and plenty of people will agree with him. It is right, however, to remember that the medical curriculum is so overcrowded, and our students so severely tested by examination that they have no time to cultivate other branches of knowledge. It is unfortunate for

learning that the new Victoria University has followed to so great an extent the evil example of the London so-called University, which has done so much to sever medicine from learning. When men are compelled to cram with useless details in such quantity that only those with excellent memories need hope to pass, how can they be expected to look at other subjects?

I know men who have not dared to look at a book or picture or listen to a concert, and who have also absolutely restricted their professional reading to the books of their examiners and such other manuals as were reputed to "tell at exam." When remonstrated with on the narrowing effect on their minds, they would say it "is useless to think of anything but learning by rote until after the degree, then poetry or literature may perhaps be enjoyed." Could anything be worse for the profession? The London University turns out men who are ignorant of everything but a few favorite books and the fads of certain teachers, and who have to begin to acquire general knowledge after taking their degree. Could there be a greater condemnation of any university?

The opening day at Liverpool was saddened by missing from his place Mr. Walker, the ophthalmic surgeon, whose death I reported in my last letter.

Birmingham, too, had a sad opening, for Dr. Russell, who had lately retired from the teaching staff, lay on his death-bed. His pupils had prepared an address expressing their gratitude and affection toward him, but he was too ill for it to be read to him at length. He was, however, told the gist of it, and that over a hundred signatures were appended. He dictated a message of thanks—his last public effort. He died on October 5th, lamented by all Birmingham, of which town he was a native, after an honorable career which leaves a noble example.

Touching of deaths, I must mention another, Dr. Stephen Monckton, of Maidstone, who for years has been a prominent physician, known in London also, but most admired in his Kentish home, where he wielded enormous influence in political and social circles without losing the confidence of the profession or the public, as so many are apt to do if they display any but the faintest interest in subjects outside their daily work. Dr. Monckton was a man of broad sympathies, earnest purpose, ardent zeal, altogether a man to admire, as well as a physician to trust. He died on September 30th, aged sixty-one, of ulcerative endocarditis.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE DEATH OF PROFESSOR CHARLES ROBIN—THE RÔLE PLAYED BY NERVOUS HEREDITY IN LOCOMOTOR ATAXY—OCULAR TROUBLES IN LOCOMOTOR ATAXY—THE ESTABLISHMENT OF AN HISTOLOGICAL LABORATORY FOR THE EXAMINATION OF MEATS BY ELECTRIC LIGHT.

PARIS, October 9, 1885.

DR. CHARLES ROBIN, Professor of Histology at the Faculty of Medicine of Paris, died at Josseron, in the Ain, whither he had gone for the summer holidays. On Monday night, the 5th inst., he had an attack of cerebral apoplexy, to which he succumbed in a few hours in the sixty-fifth year of his age. The deceased gentleman took his degree in 1845, and was shortly after appointed Professor of Histology, in which branch he eminently excelled, and consequently he was dreaded as an examiner. He was a Senator, and Member of the Institute and of the Academy of Medicine. He has not published many works, but a dictionary that he brought out some years ago in conjunction with the late M. Littré is still considered the best standard work of its kind. It is a dictionary of medicines, of surgery, pharmacy, of the accessory sciences, and of the veterinary art. In fact, it is a small encyclopædia in itself—nothing has been published like it in any other language. All it treats of is in one volume, and it will probably be consulted for many a generation to come.

In a memoir by MM. Landouzy and Ballet on the rôle played by nervous heredity in locomotor ataxy, and for which the authors were awarded a prize at the Academy of Medicine, it is shown that in 138 cases of the malady it was found that in 61 cases it could not be traced to any particular cause or to causes other than syphilis and heredity; 36 cases of heredity, 35 of syphilis, plus 7 cases of syphilis and heredity combined, and 3 cases of probable syphilis and heredity. It will be seen that these statistics notably differ from those which have been cited in favor of the predominance of syphilis as a cause of locomotor ataxy (93 to 103, Fournier; 38 to 100, Erb). These etiological researches are enveloped in difficulties; nevertheless, the results obtained by the authors are very interesting. It will be seen that the number of ataxic subjects by heredity surpasses that of those by syphilis. Whence one is led to conclude that the part of the predominant influence in the pathogeny of tabes may be referred to heredity, syphilis playing a secondary part. The authors do not depend on statistics alone to prove the correctness of their thesis; they adduce arguments of another order in favor of the hereditary origin of locomotor ataxy; such, for instance, among a number of other observations that may be found in other works, the case reported by Dr. Carré, of a family in which, during three generations, there were not less than 18 tabetic subjects, grandmother, mother, 7 out of 12 sons, then 8 near relations, all of whom were affected with tabes. Other pathological coincidences have also been pretty frequently noticed in ataxic subjects, such, for instance, as the combination in a patient suffering from progressive locomotor ataxy, and of another nervous affection, hysteria, vesania, or some mental affection; the frequent coincidence of tabetic symptoms and psychic troubles of general paralysis; divers neuropathic manifestations, epilepsy, hypochondria, lypemania, the delirium of persecution. The conclusion arrived at by MM. Landouzy and Ballet from their researches is that the nervous system in ataxic subjects is affected with some defect which predisposes it to troubles the most varied, a fact which Charcot had already noticed in his lectures. The facts and arguments brought together in their work tend to this demonstration of hereditary predisposition, which, according to the authors, is the predominating, all-sufficient, and perhaps necessary cause of tabes, the other causes, such as cold, excesses, syphilis, etc., intervening as so many accessory or occasional causes.

In connection with this subject I may mention that Dr. Galezowski, a well-known ophthalmologist, in a clinical lecture on ocular troubles in locomotor ataxy, makes the following remarks: "I fully agree with Professor Fournier as to the frequency of syphilis in locomotor ataxy, and believe with him that nine times out of ten the disease is syphilitic in its essence. My opinion is based on a considerable number of observations where the presence of syphilis was not disputable; it is supported particularly by the good effects of the treatment applied."

The Municipal Council of Paris has resolved to establish an histological laboratory at the "Halles Centrales," or Central Market, for the examination of butchers' and other viands thereat sold. It is to be placed under the direction of a veterinary surgeon who will also be well up in micrography. It will form at the same time a practical and theoretical school, serving for the analysis of doubtful meats and for the instruction of inspectors not familiar with the microscope.

In a report by M. Lamouroux, a Municipal Councillor pointed out the necessity for substituting the electric light for that of gas in the pavilion allotted to butchers, as it has been found that microscopic analysis is impossible with the gaslight, which does not enable one to distinguish the proper colors. This renders the tasks of

the inspectors very difficult, as the butchers, who are well acquainted with this inconvenience of the gaslight, take advantage of this circumstance to sell their bad meat at night instead of by day.

LACTUCA GRAVEOLENS IN DROPSY.

To the Editor of The Medical Record.

Sir: In the experimental history of the Materia Medica of Dr. William Lewis, third edition, edited by the celebrated physician and poet Dr. John Aiken, in 1784, or just one hundred years ago, we read, page 375, that lactuca graveolens, vel sylvestris, vel odorosa, vel virosa, or strong-scented, stinking lettuce, by some erroneously supposed to be the wild lettuce, was highly prized by the celebrated Dr. Collin, of Vienna, who wrote a tract recommending it in the cure of dropsies. The preparation he used is an extract from the expressed juice, first sufficiently clarified, then evaporated by very gentle heat. This comes near our fluid extracts, and is better than those made from old dried plants. He begins with small doses, but in dropsies of long standing, originating from visceral obstructions, notably perhaps of the kidneys and portal system, he rises to the quantity of from one to three drachms in twenty-four hours. He has constantly found it a mild remedy, agreeing perfectly with the stomach, and usually keeping the bowels open, but without exciting purging. It also seldom failed of proving powerfully diuretic, and at the same time mildly diaphoretic. The patients' excessive thirst was totally extinguished by its use, but all were allowed to drink freely of diluting fluids during the course. Dr. Collin asserts that out of twenty-four dropsical cases all but one were cured by this medicine, a degree of success which, Dr. Lewis says, certainly entitles it to the further notice of the medical faculty.

Did Dr. Collin tell a whopper here, or rather twenty-three whoppers, or perhaps less, or has a valuable remedy been long neglected? Stephenson and Churchill, in their "Medical Botany," London, 1831, vol. i., article 12, say they consider lactuca virosa one of the most valuable native plants. They quote Dr. Collin and say in a dropsical case that lately came under their care it certainly produced a salutary action on the kidneys, and procured quiet sleep. They also ascertained to their own satisfaction that it possesses another most important virtue, viz., that of *reducing the velocity of the pulse*, at the same time that *it increases its tone*; and so remarkably efficiently did it act in one patient that three small doses of the tincture depressed the pulse from 130 to less than 70, accompanied by intermissions. Unlike digitalis, its effects on the brain were scarcely felt.

Pereira says the milky juice of L. virosa furnishes from fifty to fifty-five per cent. of lactucarium, while that of L. sativa only gives up seventeen to twenty-three per cent. François says it allays pain, diminishes the rapidity of the circulation, reduces body-heat, and favors sleep. Buchner says the same, and Dr. Bigelow that it promotes the secretions from the kidneys and skin. Dr. Seidel, a homœopathic physician, experimented on fifteen healthy persons with considerable doses of the tincture and extract. First it caused a sense of heat in the stomach, followed by coolness. Then contraction in the stomach or heart, with real præcordial anguish; the thorax seemed compressed, with a longing for the open air and frequent yawnings. Then the head became anæmic, or, at least, confused and a little giddy, with some buzzing in the depths of the ears. Then gurglings in the stomach and bowels, with eructations and flatulence, some mucus in the throat, with cough, followed by loose pappy stools, while the urine became considerably increased. The pulse was less frequent for several days. Dr. Seidel thought it suited to some cases of hepatic, cardiac, pulmonary, and renal congestion.

John C. Peters, M.D.

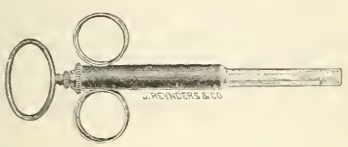
New Instruments.

A POWDER INTRODUCER.

By F. F. C. VAN ALLEN, M.D.,
Albany, N. Y.

Where it is desired to introduce a quantity of absorptive powder into the external auditory canal in the treatment of purulent otitis, a powder-blower is certainly an unsatisfactory apparatus to use. After using various contrivances I had an instrument made for me, and after employing it both in private and hospital practice for more than a year, I can say that it is very satisfactory.

This powder introducer consists of a small glass tube suitably connected with a piston. To charge it, the



piston is withdrawn to the full extent, and the tubular end is plunged into a shallow, wide-mouthed bottle containing the powder, which readily crowds up into the tube, the air escaping from a vent-hole at the upper portion. Thus charged the instrument is introduced a short distance within the meatus, and powder pushed into the canal by pressing the piston. By varying manipulation the powder can be packed firmly or loosely.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 11, 1885, *to October* 17, 1885.

Irwin, B. J. D., Lieutenant-Colonel and Assistant Medical Purveyor. Ordered from Department of Arizona to New York City, for temporary duty in charge of Medical Purveying Depot at that place, relieving Captain Henry Johnson, Medical Storekeeper. S. O. 233, A. G. O., October 10, 1885.

Morris, Edward R., First Lieutenant and Assistant Surgeon (recently appointed). Ordered for duty in Department of the Missouri. S. O. 233, A. G. O., October 10, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending October 17, 1885.

Baldwin, L. B., Passed Assistant Surgeon. Detached from Naval Hospital, Philadelphia, and ordered to Navy Yard, Mare Island.

Dickinson, D., Surgeon. Detached from Naval Hospital, Mare Island, and ordered to Training Ship Portsmouth as relief to Surgeon A. M. Moore.

Moore, A. M., Surgeon. Detached from Training Ship Portsmouth and await orders.

Shafer, Joseph, Assistant Surgeon. Detached from Receiving Ship St. Louis and ordered to Naval Hospital, Philadelphia, as relief of Passed Assistant Surgeon Baldwin.

Hester, F. A., Assistant Surgeon. Detached from U. S. S. Minnesota, and ordered to the Tennessee, as relief of Passed Assistant Surgeon Nelson H. Drake.

Drake, Nelson H., Passed Assistant Surgeon. Detached from the Tennessee, 31st inst., and await orders.

Medical Items.

Female Physicians for India.—There has just been established, under the auspices of Lady Dufferin, as lady president, a National Association for Supplying Female Medical Aid to Women in India. The object is to supply in hospital wards and within private houses that medical care and advice which respectable native women will only accept from their own sex. The association will provide scholarships for women under tuition, and will procure from Europe and America a sufficient number of skilled female medical teachers. The support and sympathy of influential native princes have already been promised, and aid from England and India is invited.

The Berlin Medical Society is house-hunting, and a very unsatisfactory task it finds it. It has recently held two trial sessions in different buildings, but has not selected either of them, and it appears not improbable when the summer vacation is over that it will find itself without a local habitation. The society numbers over 400 members, and it seems strange that it has not a building of its own.

Moss as a Surgical Dressing.—For some months past moss has been employed as a surgical dressing in the Teaching Hospital in St. Petersburg; it costs 50 kopecks a pood (25 cents for 36 pounds). The results have been very satisfactory.

A New Mercurial Ointment.—M. Ivan proposes to replace lard by soft-soap in preparing mercurial ointments (*Le Progrès Médical*). When one part by weight of soft-soap (as nearly neutral as possible) is rubbed up with three parts of mercury it is seen that the extinction of the mercury occurs as completely as with lard, and much more rapidly. The mercurial soap will keep indefinitely and does not become softened by heat, but retains its natural firmness in all temperatures. It is of itself unirritating, and is easily removed by washing. Mercurial soap would thus seem to be preferable in many ways to the ointment.

The Inheritance of Artificial Deformities.—In the course of a discussion at a meeting of the Société de Chirurgie of Paris, M. Magitot stated that for the past fifteen years, in the laboratory of the Faculté de Médecine, he had been cutting off the tails of all the rats in one descending line. But now, at the end of so long a time and after the deformity had been produced in so many generations, the rats were born with just as long tails as ever.

The Feuilleton of one of the Parisian Medical Journals consists now of a literal translation of the *Pall Mall Gazette* exposures of London vice. The tale is continued from week to week, and the feuilleton occupies very nearly as much space as does the scientific matter.

The Treatment of Pityriasis Versicolor.—Dr. W. Thornton Parker, of Newport, R. I., writes: "I notice in to-day's Record an item concerning the treatment of pityriasis versicolor, in which sulphur ointment and nitric acid ointment and the corrosive sublimate solution are recommended. All these may be good remedies, but to me they seem needlessly harsh. I find it sufficient to direct my patient to take a warm bath or sponge bath before going to bed. After this I direct that a cake of soap, common bar soap, or better still, Frank Siddall's soap, be well moistened by holding it in warm water for a moment, and then rubbed on the spot, in fact *well rubbed in*, until the soap becomes dry. The night flannel is then put on, and a cotton night shirt. In the morning the dried soap is to be *removed* by the sponge bath. The bath must be thorough, and every vestige of the soap removed. For the day wear a clean flannel every morning and a clean flannel every night until the discoloration has disappeared. The flannels must be boiled and well washed before using again. This simple treatment, carried out faithfully for a longer or shorter time, according to the extent and persistency of the discoloration, will be found successful. The application generally prescribed will not prove satisfactory in many cases, unless this plan is associated with the treatment. I am quite certain that in treating this affection harsh methods are entirely superfluous."

Malingerers in Galicia.—According to Filleabaum, the simulation of diseases has been reduced to a fine art among the conscripts of Galicia. The particular form of mutilation varies according to the different districts, in one place prolapse of the rectum being the favorite, while in another the recruits prefer to cut off their fingers. One plan which is very popular is to produce corneal opacities by a sort of tattooing process, and in one case the author observed a leech-bite on the cornea, a method that had been employed by over thirty men coming from Kars. Nystagmus is often simulated, but the deception is made evident by irregularity in the rhythm during a prolonged examination. The author saw twenty cases of artificial subluxation of the shoulder. The arm was abducted, the head of the humerus being displaced toward the axilla and fixed so that the scapula followed the movements of the arm. The muscles were strongly contracted, and the inner edge of the scapula was raised as in paralysis of the serratus magnus. A very moderate pressure was sufficient to reduce the dislocation, but it was at once reproduced by a sharp contraction of the muscles. Emaciation was caused by fasting, purgatives, and abstention from sleep. Twenty young Jews from the district of Zolkien were sent to the hospital for this cause, but refused to eat anything but bread, saying that the food was not prepared according to their rites, and it was found necessary at last to give them their discharge.—*Journal de Médecine et de Chirurgie Pratiques.*

Explosive Physic.—A list has just been published, in the *Union Pharmaceutique*, of accidents which have recently occurred during the preparation or carriage of explosive substances used in medicine. At Strasbourg, a chemist's assistant was changing some lycopodium-powder from one bottle to another; the particles that escaped mixed with the air, a jet of gas was burning, and a slight explosion occurred; the frightened assistant dropped the jar containing the lycopodium, the room was at once filled with the powder, and a violent explosion took place. Chlorate and permanganate of potash are also dangerous. M. Meyet has stated that a tooth-powder composed of chlorate of potash and cachou has been known to explode in the mouth of a person engaged in brushing his teeth. A druggist who dried some hypophosphite of lime in a receptacle containing sand was killed by its explosion. Oxalate and citrate of lime are also explosive, but only at a high temperature. Pills of permanganate of potash have been known to explode spontaneously. A mixture of perchloride of iron and glycerine exploded in the pocket of a patient who carried it. An eminent chemist at Paris prepared ozone with powders composed of equal parts of peroxide of manganese, permanganate of potassium, and pulverized oxalic acid; he took every recognized precaution, and the mixture was corked up in a bottle; a few minutes afterward an explosion took place, and the bottle was reduced to atoms.—*British Medical Journal*, August 1, 1885.

The Practical Results of Sanitation.—The effect of sanitary improvements upon the health of a community is well illustrated in the case of Merthyr Tydvil in Wales. In this place, during the last thirty years, sanitary improvements have lessened the death-rate from 332 to 232 per 10,000, while the average age of death has been increased from seventeen and a half to twenty-seven years.—*The Sanitary World.*

What the Chinese Eat.—That "one-half of the world does not know how the other half lives," is as true of eating as of anything else. Many of us, no doubt, have experienced a pharisaical satisfaction in contrasting the dainties which tickle our palates with the ragoûts, fricassées, and consommes of dog, cat, and rat, which we have believed to be the choicest tidbits of the heathen Chinee. It now appears that these animals form no part of a Chinese menu, except in the case of some cranky individuals who are found among the Celestials as well as among the Yankees. Now and then a Chinese woman resorts to rat-flesh to restore her fallen hair, or a man eats cat-steak to renew his blood, and persons too poor to buy even "bread and cheese," eat dog-soup rather than starve. But a gentleman who has lived fifteen years in China, and associated with all classes of people, avers that he has never seen cat, dog, or rat-meat served in any form whatever. "What, then, do the Chinese eat?" was asked of a Chinese gentleman, and *Wide-awake* gives his reply as follows: "Chinese gardens are prodigal of vegetables; our ponds, rivers, and lakes swarm with fish; our farm-yards are crowded with pigs, land-fowls, ducks, and geese; our fields are gilded three times every year with ripening rice. In some sections of the empire wheat and barley are produced; but rice is our usual substitute for bread. These articles make up the every-day food of the people. But there are certain things unknown to your tables that are considered great delicacies by everybody, one of which is edible birds' nests. Another is shark's fins. The Chinese do not keep many cows, and it is true that beef is not esteemed as good as pork, and that many will not eat beef on account of religious scruples. Milk, butter, and cheese are almost unknown articles of diet. The Chinese think it is robbing the calves to take milk from the cows."

A Sure Cure for Cholera.—The Spanish medical journals are publishing a letter addressed to them by a French physician, Dr. Laubie, who claims to have discovered something which is "really a sovereign remedy against cholera." It is, he says, very rapid in its action, an improvement being experienced within half an hour, and the course of the disease being thenceforth a rapid one toward recovery. After thus raising the expectations of his readers to the highest pitch, he forgets to state what his specific is. It is a peculiarity of "sure-cure" doctors the world over to keep the nature of their remedies secret.

Genius or Madness?—The *Medical Times* gives the following particulars about Victor Hugo: His uncle died insane; his brother, Charles Hugo, who at an early age gave promise of great literary talent, became insane before twenty, and spent the latter part of his years in a hopeless state of dementia; and one of the poet's daughters, still living, is the inmate of a "maison de santé." That in a family thus tainted with insanity a man of immense genius should arise is only another instance of that close hereditary connection between mental disease and highly intellectual powers which Moreau de Tours so forcibly pointed out in his celebrated book, "La Psychologie Morbide;" but any impartial reader will find in many of Hugo's best writings a large number of passages which could only have been conceived by a diseased imagination, and which bear the indelible stamp of madness. In this respect the French poet widely differs from his great prototype, Shakespeare, who in the wildest flights of his poetical phantasy still remains faithful to sound common sense. The mind of Shakespeare was evidently a healthy one; that of Hugo was not; and if some future Plutarch attempts to strike a parallel between these two great literary giants, he will do well to keep this fundamental difference in view. It may seem ambitious to compare Hugo to Shakespeare, but in this city and at the present day most people seem inclined to place the modern poet above the older bard, an exaggeration which time will doubtless dispel. Yet, as regards the conduct of his private affairs, no man could excel Victor Hugo in that shrewdness which persons "not quite right about the head" so often exhibit. No banker could more carefully have managed his fortune, no politician could more tenderly have nursed his popularity; and the man who left a fortune of more than two hundred thousand pounds sterling was the idol of a jealous democracy, while the politician who played at fast and loose with all parties was buried in the midst of universal applause. Such an instance of great "wit to madness near allied" the annals of the civilized world have never hitherto placed on record for the edification of posterity.

An Illinois "Ten-Year Man."—At Carbondale, Ill., there once lived a pretentious old quack—"a ten-year man"—by the name of O'Haven. One day he lounged into a store where were several of the more reputable physicians of the town and a literary man. The literary man knew of the ignorance of the quack and concluded to expose it, and, to do so, inveigled the pretender into a scientific conversation. Turning to one of the more reputable physicians present, our literary friend, with a significant wink, began: "Dr. R., what do you think of the controversy in the *Lancet?*" Dr. R.: "Well, the fact is, I haven't made up my mind about it." Literary Man: "But, doctor, don't you think it strange that so important a question as the position of the liver should not have been settled before this? I have always thought that there was no doubt but that the liver was situated above the diaphragm." Dr. R. (taking the hint): "Well, it's not so strange after all. I've seen cases in which it was hard to tell. I confess, however, I have been of the opinion that in most cases, at least, it was below the diaphragm." L. M.: "The question is certainly an important one, or the London *Lancet* would not spend so much time and space discussing it. Ah, there is Dr. O'Haven! Doctor, you have had great experience; what is your opinion on the question that appears to be vexing the professional mind?" Dr. O'H. ("ten-year man"): "Well, sir, that is a question to which I have given a great deal of attention. From my long study and extensive observation I have, however, been able to settle the matter beyond all dispute. The liver, sir, is situated *half above and half below the diaphragm!*"—*Cincinnati Medical Journal*, August, 1885.

Aqua Camphor, not Tinct. Camphor.—A correspondent says: "There is a serious error in Milner Fothergill's paper, p. 227, August 29th issue. The writer means aqua camphor, undoubtedly, as an ounce of tinct. camphor at one dose would be fatal, and a drachm is sufficient to cause in most people violent and dangerous convulsions."

Wounds of the Heart not Instantly Fatal.—Dr. Charles H. Cockey, of Baltimore, Md., writes: "In regard to wounds of the heart, Elwell, in 'Malpractice and Medical Evidence,' page 568 (edition 1866), says: 'A British soldier survived for thirteen days with a musket-ball in his heart. In a case tried in Glasgow in 1819, the medical evidence showed that the auricles and part of the aorta next the heart were destroyed by slugs and brass nails with which the piece was charged, and in that case he must have dropped down dead the moment he received the shot. But the evidence showed the body to have been found some distance from the door where the prisoner claimed to have shot him, as he was entering his house by force, as a stream of blood was found from the door to the place where the body lay. It was determined that the prisoner did not run into the street and shoot the deceased, but that the deceased did run from the house to the spot where he lay, though shot in the manner described. The prisoner was discharged.' In the *New York Medical Journal*, vol. xxviii., December, 1878, page 634, Dr. V. P. Gibney relates the following history as sent to him by Dr. F. M. Holly, of Greenwich, Conn.: 'A man, aged eighteen, was accidentally shot,

July 7, 1878, by a Smith & Wesson revolver, calibre 22. He was seen by Dr. Mead an hour after the injury, and was then in a state of partial collapse, from which he subsequently rallied. He had no remembrance of the shooting, or of having fallen into a brook near to which he was sitting. He recovered quickly without any unfavorable symptoms, except slight dyspnœa and slight pleuritic pain on both sides for a few days, and at the expiration of a fortnight was sufficiently well to resume work. He was engaged as a farm-hand, and was able to do his usual duties till August 30th, when, after a hearty breakfast, he went into the field, and was found, after twenty minutes, dead behind the plow. Upon examination a small cicatrix was seen near the left nipple, an inch and three quarters above and toward the median line. On opening the thorax, the left pleura and pericardium were found distended with serum and coagulated blood. A small cicatrix existed on the upper lobe of the left lung in line with the external cicatrix. Beneath, an opening one-fourth of an inch in diameter was found in the pericardium. . . . Opposite the opening in the pericardium, and on the anterior surface of the right ventricle, a small aneurismal sac, the size of a hazel-nut, was found ruptured. The walls of this sac were very thin, and a probe introduced in the rent passed into the ventricular cavity. The rupture of this aneurismal sac was the cause of the extravasation of blood into the pericardium and pleura with sudden death. . . . Dr. Gibney said that when he received the specimen, he opened the left ventricle and found the ball lying behind one of the pillars of the columnæ carneæ, above and to the left of the apex of the cavity. On a more careful examination, an opening was traced through the upper portion of the septum and contiguous semi-lunar valve, through the aorta itself, to the left auricle. All these openings were found on a line with the opening into the right ventricle.' . . . But undoubtedly the above cases are known to you."

Brutal Treatment of a Physician.—The following is an illustration of the sort of treatment to which physicians in the cholera districts bordering on the Mediterranean are exposed at the hands of the ignorant and frightened populace: At Puebla Larga, near Barcelona, a man died of cholera. The relatives told not a soul of what had happened, but, assembled in the front room of their cabin, awaited the arrival of the doctor on his daily round of visits, and when he came asked him quietly, as though all was well, to step in and see his patient. What was his astonishment on drawing near the bed to find that it held a corpse, and, on turning around, to see himself surrounded by the relatives, whose appearance had now become most threatening. They demanded of him what right he had to take their money without curing his patient, and called him a murderer, saying that this was the third person he had deliberately killed in one week. Then the wife of the dead man gathered all the medicines, pills, liniments, disinfectants, and the rest, which the unlucky physician had prescribed, and while the others held him down and forced open his mouth, she emptied the contents of all the boxes and bottles down his throat. For twenty minutes this man was held down while the fiend of a woman poured carbolic-acid solutions, hot liniments, drugs, one after the other, into her victim's mouth. An hour later he was dead. And in two days his father was also dead from the shock which the news of his son's fate gave him.

The American Medical Missionary Society was organized last March, with headquarters in Chicago. The objects of the Society are to assist young men desirous of becoming medical missionaries in obtaining a thorough education, and in qualifying themselves practically for the work which they will be called upon to do; to establish medical mission stations and dispensaries abroad; to supply medical missionaries with the necessary medicines and instruments, etc. The constitution is modelled upon that of a similar society which has been in existence for some time in Edinburgh. The objects of this society are laudable, and we wish the promoters of the work every success. But we cannot approve of some of the statements set forth by the Society in its "Plea for Medical Missions." One of these is, that in some parts of China, in case of delayed child-birth, if the child is not tempted to come into the outer world by a bait of rice spread upon the floor, "the woman is placed upon the floor and actually jumped upon." It may have happened some time or other that a Chinese woman was jumped upon while in labor, just as it has happened in our own happy land that women in childbirth have been jumped upon, but that such is an established custom in China any more than it is in America we know on excellent authority not to be the case. And the American Medical Missionary Society, or any other Missionary Society, will do no good and convert no heathen by giving circulation to such old wives' fables. However, we hope the Society, in spite of its "plea," will gain many recruits for medical work in uncivilized lands, for although the Chinese are not brutes by nature, they are lamentably deficient in the knowledge of the treatment of disease, and well-educated physicians may accomplish much good among them. The Secretary's address is 206 Twenty-eighth Street, Chicago, Ill.

Iodoform and Carbolic Acid.—It is not uncommon to read in accounts of operations that the wound was covered with iodoform over which carbolized gauze was applied. This practice is said by Mosetig-Moorhof to be wrong, and he attributes to this mixing of iodoform with various antiseptic acids most of the ill effects which have been unjustly laid to the door of the pure iodoform.

Arseniate of Gold.—A correspondent of *La Crónica Médica*, of Valencia, writes that arseniate of gold, which has been said to be a therapeutic agent of no mean value, does not and cannot exist. In order to make it, he says, it would be necessary to combine the protoxide of gold, Au_2O, with arsenic acid, AsO_5. But as the protoxide resists the action of the strongest acids, it is to be inferred that arsenic acid cannot affect it, and it is therefore, he reasons, impossible to have an arseniate of gold, therapeutists to the contrary.

Bacteria in the Air.—M. de Parville has published a paper on the presence of bacteria in the air we breathe. He says that the proportion of bacteria in a cubic metre is 6 in sea air, 1 in the air of high mountains, 60 in the principal cabin of a ship at sea, 200 in the air at the top of the Pantheon in Paris, 360 in the Rue de Rivoli of Paris, 6,000 in the Parisian sewers, 36,000 in old Parisian houses, 40,000 in the new hospital of the Hôtel Dieu of Paris, and 79,000 in the old hospital of Pitié in Paris. In Ryder Street, St. James's, London, a cubic metre of air contains only 240 bacteria, whereas in the Rue de Rivoli the same quantity of air contains 360. M. de Parville maintains that the superiority of London air as compared with Paris air is shown not only by the London air containing fewer bacteria, but also by the London rate of mortality being smaller. The greater purity, or less impurity of the air of London than that of Paris is accounted for by London being nearer to the sea, by its covering a larger extent of ground in proportion to the population, and by its houses being lower.

Tincture of Cobweb.—A correspondent writes that he has seen tincture of cobweb mentioned as of use in intermittent fever, but has been unable to find mention of any such tincture in any work to which he has access. He inquires where he can find a description of the manner of preparing it.

The Treatment of Mastitis.—Dr. J. A. Stilwell, of Brownstown, Ind., does not think there should be any controversy as to priority in treating mastitis by compression and rest. He has been treating it that way for ten years, and is sure it is not original with him, he having got the idea from an item in some medical journal.

The Medical Record

Original Articles.

THE CHOICE OF REMEDIES.[1]

BY LAURENCE JOHNSON, M.D.,

NEW YORK.

TWENTY years ago there was much less faith in the efficacy of drugs in the treatment of diseases than there is to-day. One of our most prominent medical teachers and authors was wont to say in those days, that medicine was worth all the study given to it, if for nothing else than to enable the practitioner to make a diagnosis and prognosis. And this remark meant far more than appeared in the mere words uttered, for while the carefullest attention was paid to the diagnosis, clinical history, prognosis, and pathological characters of disease, the treatment was dwelt upon in such general terms as to mean anything or nothing. In other words, disease was considered principally from the natural history standpoint, and the catalogue of self-limited affections, with whose natural course the physician should not meddle, grew to uncomfortable proportions.

It is unnecessary to discuss the causes of this particular form of medical scepticism. That it existed cannot be questioned; and that its existence operated as an obstacle to the success of medical men educated with that lack of faith is equally capable of demonstration.

Naturally this heresy, like many others which for a time have ruffled the current of popular belief, did not long survive; but none the less, like some other heresies, it led a train of evils that long outlived the cause which produced them. A generation of medical men went forth to unlearn the false precepts of their teachers by the hard road of practical experience. One cannot but smile at the pitying contempt which the recent graduate of twenty years ago had for the simple faith of the old practitioner, who actually believed he could with drugs moderate the course of a pneumonia or cure a rheumatism. Yet such was the fact. This evil was, however, of a somewhat personal character and served chiefly to handicap the individual practitioner. The faith of the public remained unshaken, and he who ministered most successfully to the public was most substantially rewarded. In reviewing this subject in the light of personal experience, bearing in mind also the experience of professional friends with whose history I am familiar, I am fully convinced that to this sceptical training more than to any other one cause, are due many of the difficulties encountered in the early years of practice.

But other evils followed. If drugs were of doubtful efficacy, they could not be dispensed with. As already remarked, the public faith remained unshaken. The public, when sick, would have drugs. The theory of the self-limitation of disease, together with the apparent financial success of homœopathic practitioners, who, it was believed, administered pleasant-tasting or altogether tasteless medicines, while the disease ran its natural course toward recovery or death, pointed the politic road—that of making medicines as palatable as possible. And here seems to me to be the origin of one of the greatest evils from which we, as a profession, and our patients are suffering. From striving to render remedies more and still more palatable, efficiency has been largely sacrificed to elegance, and unless the tide be stemmed in some way the whirligig of time will again bring around an era of scepticism, based, however, upon a more substantial foundation. While I would not for a moment decry elegant pharmacy, within reasonable limits, I do most vehemently protest against its abuse, as at present so largely practised. Granting for the sake of argument that the proprietary pills, elixirs, and other compounds so largely used are compounded in accordance with their published formulæ, it cannot be doubted that their use begets in the physician a routine practice altogether at variance with the intelligent exercise of his calling; and the more skilful he may be in diagnosis, the greater is the contrast of his treatment. But in very many instances, at least, these preparations do not contain what is claimed for them. This has been shown again and again by chemical analysis.

Then how shall we be guided in the choice of remedies to use in the treatment of disease? This question seems to me easily answered in words though practically it requires more thought than has been our custom to bestow upon it. In the first place, we should bestow upon materia medica and therapeutics the same careful study as is commonly given to other departments of medicine; the same careful attention to details as, for instance, is exemplified in practical, and consequently, successful antiseptic surgery. Knowing first the remedies within our reach, not by name merely, but having a practical familiarity with them as individuals, an intelligent appreciation of their properties and effects, and of their comparative relations to each other, we shall be prepared to use them intelligently.

But one may say, this of itself would require the study of a lifetime. By no means. Let one but learn to distinguish the wheat from the chaff, and the materia medica will, so far as he is practically concerned, soon shrink to comparatively small proportions. Suppose the practical surgeon were to provide himself with all the instruments which have been used since surgery began to be practised, how many of them would he employ to-day?

Our materia medica is certainly anomalous. Every root and herb at any time employed, from Hippocrates down, must needs be included, together with almost every chemical which man's ingenuity or nature's fertility has provided. But how many of them are used? How many are worthy of use? Hardly a larger number than of surgical instruments. So while in surgery the antiquated are labelled and placed in museums, in materia medica the good and the bad, the useful and the demonstrably useless are left side by side as if for use together.

While everyone is familiar, at least in a general way, with the articles of standard worth of the materia medica, few have paid sufficient attention to the subject to enable them to pass a decided judgment upon the great number of useless and inefficient ones; and it is in behalf of these little known drugs that our credulity is most frequently appealed to by blind enthusiasts or designing speculators.

The properties, uses, and limitations of the minera preparations of the materia medica are pretty well recognized and understood. Take the preparations of iron, for instance. Everyone recognizes that though iron in any form is a tonic, yet there is a wide difference in the applicability of different preparations to different con-

[1] Read before the Section in Practice of Medicine of the New York Academy of Medicine, October 20, 1885.

ditions. The same may be said of mercury, potassium, or sodium. The facts regarding these minerals are firmly fixed in our minds, simply because the knowledge of them is classified. Now, if the same plan be pursued with drugs of vegetable origin, our knowledge of them would be just as readily available. In a general way, the individual plants comprising a great natural family, may be said to be as nearly related to each other as are the different chemical compounds of iron to each other. Take, for instance, the order Solanaceæ, which furnishes us, among others, belladonna, stramonium, hyoscyamus, and tobacco. In these four plants we have about all the efficiency that this order is likely to afford us in the way of narcotic agents. Each one of these has a sphere of applicability almost entirely its own. This fact being conceded, why waste time and energy in fruitless experimentation in search of possible new agents in the order?

Take, as another instance, the great order Labiatæ—the mint family. We are all, I trust, reasonably well acquainted with the properties, uses, and limitations of peppermint. Well, now, this plant in itself represents all the medicinal activity of the entire order—a very large one. Other plants have different flavors, and may on this account be more or less agreeable to some persons, but their medicinal action is entirely similar if not absolutely identical. And yet it is not uncommon to find specific effects attributed to plants of this order, and some men believe it. The Cruciferæ, the mustard family, affords another instance of similar character. Mustard-seed represents all that is to be extracted from the order; all the rest may be dismissed without thought or hesitation. And so one may pursue his course through the vegetable materia medica, excluding, without hesitation, scores upon scores of drugs which but encumber his path.

When one has gone through the materia medica in this manner, and excluded the articles which reason and common sense convince him are beneath his notice, he will be ready to make his choice from those which remain, of the remedies to use. And here I would not wish to be misunderstood. For my own purposes I exclude a large number of drugs, not because they are altogether valueless, but because there are others much more efficient, and it seems to me that we should choose for our use only the best attainable. To illustrate, the number of vegetable tonics is very great. Almost anything bitter is possessed of tonic properties. Now, almost any vegetable bitter may be used in such a manner as to cure intermittent fever. The bark of the flowering dogwood, magnolia, tulip tree, or willow will do it, as will also tansy, wormwood, or boneset, but what man of sense would think of employing any of them when cinchona or its derivatives are attainable?

I believe it was Sam Patch who died while making an effort to prove "that some things can be done as well as others." It seems to me there is considerable Patch-work in medicine of a similar character, only it is not the operator who dies in the experiment.

But, some one may say, such a course as this would commit a man to contentment with his present choice of remedies for the balance of his professional life. Not at all. By accepting the verdict of his predecessors as to the worthlessness of certain drugs, he in no way binds himself to reject new discoveries with claims that can be substantiated. He will, however, be less credulous, and, on this account, less likely to experiment with anything and everything to which his attention is called.

Moreover, such an examination of the materia medica would show upon what an unsubstantial foundation the claims of many of the articles rest. I have, in not a few instances, traced back the history of a drug from author to author till I reached the original statement that it was used for such and such purposes by the aborigines. And in some cases it has been easy to observe that the original statement was copied by one after another with very little variation, the later authors including the article simply because their predecessors included it. Such medical histories of drugs, should, I think, make us slightly sceptical, and so this scepticism does not reach the point of blind prejudice, both we and our patients will be the better for it.

In days when journals are published for the sole purpose of pushing new remedies into notice; when men are employed directly or indirectly for the express purpose of manufacturing reputations for drugs, of which the proprietors of the paper have a monopoly, a little judicious scepticism is not far removed from wisdom.

However uncertain medicine may be, however inexact as a science, however disheartening it may often be in practice, it does present some things which are sure. Having, then, excluded from our materia medica the things which we consider beneath our notice, we can begin our choice of remedies for daily use by accepting at once all those whose reputations rest upon a solid foundation.

Of remedies of vegetable origin, we should probably err little in accepting all those which yield to analysis any principle capable of producing physiological effect upon the human system, taking into account, of course, the relation of the quantity of the crude drug to the principle found, and the amount of the latter required to produce sensible effect.

Of drugs which do not meet this requirement—the possession of a demonstrable active principle—we have at least the right to reserve our judgment. Accustomed as medical men of the present day are to look for a cause of every effect observed, it seems to me only rational that they should demand the reason why a drug does thus or so, and if this be not forthcoming, they have the right to expect a very clear demonstration of the fact that a therapeutic effect is produced before accepting it.

It is an easy matter to say that a drug produces good effects in this or that diseased condition, and not very difficult to compile statistics from medical literature in support of one's statements, but let one attempt to verify such statements by actual experiment, and he often finds the task a hopeless one. I refer, of course, to drugs having no appreciable active principle capable of producing physiological effects, at least in doses proportioned to the amount of the drug employed.

Take, as an illustration, viburnum, a drug introduced a few years ago as "nervine, antispasmodic, astringent, diuretic, and tonic, and especially useful in the nervous diseases of pregnancy and in the prevention of miscarriage" (U. S. Disp., p. 1521). Let anyone endeavor to verify these claims, and he will appreciate the difficulty of the task, and probably end with the conviction that the drug is wholly useless. Such, at least, has been my own experience. And yet viburnum is employed to a very considerable extent, notably in threatened miscarriage. If the patient does not abort, the drug gets the credit; if she does, why the case was too far gone to be influenced. While we as practitioners of rational medicine, so called, are uniformly sceptical regarding the therapeutic claims made by practitioners of other schools, and rarely esteem their statistics worthy of serious consideration, we will find plenty of just such unreliable material much nearer home if we care to search for it

As with viburnum, so with many other more or less fashionable remedies—their reputed efficiency is commonly greatest in cases incapable of demonstration. Of such remedies we should choose, at most, a very small supply.

But with all the drugs of vegetable origin possessing demonstrable active principles at our command, we still have more than we need, and further discrimination is necessary in order that our armamentarium be not too unwieldy. Classification of the most important ones, based upon the effects which they produce, is essential to final selection. Such a classification must, however, of necessity be artificial and somewhat arbitrary, because

of the varying effects produced by one and the same drug in different doses and in different conditions. Illustration of this point is scarcely necessary. Everyone has in his own mind, or should have, the drugs which he employs thus classified to a greater or less extent, but not every one uses wise discrimination in selecting the proper drug from a given class when prescribing at the bedside. How many of us use opium unnecessarily? How many employ quinine antipyretically, without rhyme or reason? How many administer ergot, digitalis, arsenic, or strychnia without careful consideration?

Having by the analytical course which I have endeavored to sketch, reduced the materia medica—both organic and inorganic—to a reasonable compass, and having those remedies which we will permit ourselves to employ classified, how shall we be guided in making the final selection? For the choice of proper remedies at the bedside is, of course, our ultimate end and aim.

This question appears to me to involve three considerations, namely, 1, efficiency; 2, liability to do injury; 3, ease or difficulty of administration.

There can be no question about the advisability of always using the drug which will most certainly produce the therapeutic effect desired, save as this may be modified by its liability to act injuriously upon the patient. This is a very important consideration. For example, opium is very potent in relieving pain, and, judiciously used, seldom does harm. And yet it cannot be safely used in very young children; and it should not be employed in adult life one moment longer than absolutely required, owing to the danger to the patient of the formation of the opium habit. I know that this danger is often exaggerated, but it does exist, and we should bear the fact distinctly in mind when we prescribe at the bedside. The same may be said of chloral, and of the inhalation of ether and chloroform. These drugs should never be used indiscriminately; the question of their efficiency should always be modified by their possible dangers, and when these dangers are greater than the ills for which it is proposed to use them, they should be replaced by safer, though less efficient, drugs. Take, as another instance, aconite, veratrum, and gelsemium, all used as arterial sedatives indiscriminately—commonly, however, by different physicians. Considered merely from the standpoint of efficiency, there is little choice between them, but a consideration of their relative dangers shows them in an altogether different light. Aconite need never do harm; veratrum often produces unexpected vomiting, purging, and dangerous depression; and gelsemium is nearly as unreliable as lightning. So that you may use aconite with safety, veratrum with fear, and if you push gelsemium, you should do it with positive dread of the possible consequences.

I might go on illustrating this point almost indefinitely, by comparing the drugs of different classes with each other, but it is unnecessary.

It remains to consider the efficiency of drugs as modified by the difficulties of administering them. As previously intimated, it has been more or less the fashion to consider this first. As this involves the question of how best to administer the drugs we have chosen, it deserves rather more attention than my limits will permit.

The patients to whom we administer drugs may be divided into three classes: 1, those who are so ill as either to offer no objection to swallowing anything prescribed, or, on the contrary, strenuously objecting to everything. To the latter division of this class may be added young children accustomed to rule the house; 2, people who, though perhaps not quite sick, are still not wholly well, and who consume medicine largely as a matter of habit; 3, people who consult physicians for want of some more active employment.

The first class of patients, those who are really ill, of course, comprises the bulk of those with whom there is any difficulty. With adults not too sick to appreciate their condition, and consequently both able and willing to co-operate with us, there is commonly little trouble in administering anything necessary, and we are only required to choose the most efficient preparation of the drug desired. And here at once arises the vexed question, what are the most efficient preparations? If we are willing to accept the opinions of those who claim to be extremely solicitous for our welfare—the manufacturing druggists—we can have this question settled for us readily in the shape of A's pills, B's granules, C's fluid extracts, etc. If, however, we consider it among ourselves, we shall probably reach different conclusions. Now, it is the habit of some to consider the alkaloids or other active principles of vegetables as the most efficient preparations, and to use them exclusively, making morphia, for instance, represent opium, atropia, belladonna, strychnia, nux vomica, and so on, overlooking the fact that these alkaloids do not fully represent the drugs from which they are derived. In other words, they fail to recognize the fact that there is a time to administer morphia, and another for solid opium; that, while strychnia has its uses, nux vomica has its peculiar sphere. Moreover, the extreme practitioners of this class often employ these potent active principles in the form of gelatin or other coated granules, whose ready solution in and absorption from the alimentary tract is a matter of conjecture. I am not in sympathy with this mode of practice; still less with that whose commonest dose-measure is the hypodermic syringe. The best preparation of a drug I conceive to be that which most completely represents the crude article; and, of vegetable remedies, this is more commonly in a liquid form. I would relegate alkaloids and other active principles to their proper place, and use them in solution, if practicable, by the mouth when possible, otherwise only when necessary. And when necessary to employ remedies in pill form, these should be freshly made, commonly by extemporaneous prescription, rather than turned out by the thousand dried, coated, polished, and impregnable. And I firmly believe there would be much less complaint of the uncertainty of drugs if they were employed in this manner.

And here I wish to add one word for the benefit of those whose bugbear is *polypharmacy*—the giving of numerous drugs in one and the same dose. I see nothing irrational in the intelligent combination of drugs, and, theoretically, at least, no limit as to the number which may be thus combined and administered at a single dose. On the contrary, it seems to my mind much more commendable than the practice of frequent alternations, which only serves to annoy the patient. A young physician, in my hearing, once boasted of his physical endurance in watching with a patient six weeks, and administering medicine every fifteen minutes. Though the patient lived, I hardly consider the case as evidence against the wisdom of combining remedies, if for no other purpose than to lengthen the intervals between doses. With remedies chosen in the manner indicated, I believe there will occur little difficulty in treating all really sick people whose co-operation is obtainable. Regarding the obdurate, and the fractious children, I have no suggestions to make. Certainly the most elegant pharmacy will be of little avail.

As to the second class of patients, the habitual medicine-takers, why, it is altogether immaterial. If they require medicine at all, give it in the most efficient form, without regard to taste. On the whole, I think a decidedly bad-tasting mixture, one which stays by them, suits them best. Certain it is that some of the vilest tasting proprietary compounds have had the largest sales, and not because they restored those who consumed them, either. The same is true of pills: those which are most drastic are most highly appreciated.

Regarding the third class, still less need be said. They consult you, as I have said, for the want of more active employment. If you care to bother with them at all—it is business that pays—let them have *elegant pharmacy*, the more elegant and the less efficient the better.

THE CLINICAL RESEMBLANCE OF TYPHOID FEVER AND ACUTE TUBERCULOSIS, AS ILLUSTRATED BY A CASE.[1]

By JOSEPH EICHBERG, M.D.

CINCINNATI, O.

Among the few diseases which the student is taught by nearly all text-books of practice of medicine to consider as possible, in making a diagnosis of typhoid fever, is acute miliary tuberculosis. The statement is generally made without any qualification or further explanation, and the student is left to reconcile, as best he may, the types of disease as he will find them carefully traced in this same text-book. There is to him great difficulty in understanding how the regular fever curve of typhoid, with its easy and accurate subdivision into first, second, third, and fourth weeks, can be in any way counterfeited by the fever line of the tubercular disease, and most puzzling of all, is the fact, that an affection characterized by so many local symptoms as typhoid, should possibly be mistaken for a generalized infectious process, invading simultaneously, or in rapid succession, nearly all the important viscera with their investing serous membranes. The student is apt to overlook two important facts, which may even escape the attention of the more advanced practitioner. These are firstly, that the typical fever-line of typhoid does not apply to all—scarcely, I should think, to a majority—of the cases observed here (and in this statement I am borne out by the recorded experience of the large Cincinnati Hospital); and secondly, that an acute tuberculosis may be localized as to symptoms, and often in its anatomical distribution to one great serous cavity, leaving the others entirely free, or affected so slightly as to cause no special symptoms. The impression most likely to be left in his mind from his reading, and from his didactic lectures, is that acute miliary tuberculosis means a development of tubercles in the brain, lungs, liver, spleen, intestines, mesenteric glands, arachnoid, pleura, and peritoneum; and I must confess to having retained this idea myself until a very recent date, when I found in a number of autopsies made upon patients dying of phthisis or of tubercular disease the actual distribution of the disease limited very frequently to the peritoneal cavity, leaving the lungs, the supposed starting point of infection, entirely unaffected by gray tubercle, though the signs of lobular pneumonia were frequently, not invariably, present.

The easy possibility of a clinical mistake was brought home to me by a case of my own, of which the following is a brief history:

A. B——, aged twenty years, American, a young man of exemplary habits and good social standing, was seen on the evening of July 15th. He complained of considerable pain in the abdomen, which he located in the right iliac fossa, and which he said had annoyed him for twenty-four hours; it had not been very severe through the morning, so that he rode into the suburbs, some four miles, being forced to return, however, by the increasing discomfort late in the afternoon. There was rather an anxious expression of face, the skin was hot, the temperature, 101.4° F.; pulse, 98, and the respiration, 18. Physical examination showed a very flat chest, the boy being remarkably tall, the muscles not very well developed, the body being rather thin, though not badly nourished; the lungs and heart normal. There was considerable tenderness on deep pressure in the right iliac fossa, some tympanitic distention of the entire abdomen, and the knees were flexed. There was loss of appetite, but great thirst. The tongue was slightly reddened, but moist and soft, and it was a noteworty fact, that, from the beginning to the end of his illness, there were never present, for as much as a single day, the changes which this organ records in typhoid. There was no redness at the sides, no V-shaped redness at the tip; no swelling, dryness, white or yellowish coating, no fissures or furrows, no sordes on lips or teeth; from first to last the tongue remained smooth, comparatively pale, moist and flexible, was never tremulous or protruded with difficulty, and only toward the end bore indentations of the teeth, as a sign of general muscular relaxation, such as accompanies all conditions of exhaustion. It happened that just at that time the hospital wards had received several cases of typhoid, that a case of peri-typhlitis and subsequent general peritonitis under my own observation was convalescing, and I at once expressed an opinion that the case was likely to be protracted. He was ordered quiniæ sulph., gr. iij.; pulv. opii., gr. ¼, every three hours, and a strictly fluid diet, to consist largely of milk.

At 4.15 A.M., July 16th, he had a violent chill, lasting about fifteen minutes, after which the temperature rose to 103°, the pulse to 120, and the pain in the abdomen slightly increased. Hot flaxseed poultices, large enough to cover the entire abdomen were ordered to be changed every half hour. The bowels were constipated. The fever gradually declined toward evening, but at 9.30 P.M. he had another chill, not so violent and of shorter duration than that of the morning.

July 17th.—A.M.: Temperature, 101°. Considerable distention of the abdomen; gurgling in the right iliac fossa; abdomen still tender; slight increase of resistance when pressing over right iliac fossa. Temperature, P.M., 101°; pulse, 96.

July 18th.—A.M.: Temperature, 102.4°; P.M.: temperature, 101.5°. Had an attack of epistaxis during the day. Otherwise symptoms unchanged.

July 19th.—Slight diarrhœa; two or three stools; temperature, 101°; pulse, 96.

July 20th.—Abdomen not so tender; tympanites diminishing; appetite fair. Is troubled with slight headache.

July 21st.—Temperature, 99°; abdomen becoming soft; says he can make pressure at any point without giving rise to pain. Feels very much easier; no diarrhœa.

On the 23d of July, having been free from pain for several days, the evening temperature not having risen above 99°, as tested in the mouth, he was allowed to get up, having received a caution as to remaining perfectly quiet and not attempting any exercise. However, the boy felt himself so well, that he walked several times into an adjoining room, spending the greater part of the day on a sofa there, and returning to his bed at four in the afternoon. In the evening, he complained of a slight return of his pain, and slight diarrhœa set in, two or at most three stools a day, light in color and of rather pasty consistency. His diet was limited to milk, of which he took about three pints daily.

On July 24th, the temperature was 99.4°; in the evening, 100°. It were a monotonous repetition to give the daily record of his illness from that date to August 2d, when a decided change for the worse set in. In those nine days, there was comparatively little change in his condition, the diarrhœa not again manifesting itself, the temperature remaining at or nearly at 101°, with a distinct tendency to morning exacerbations, the appetite varying from day to day, the pain in the bowels gradually getting better under the use of hot poultices most assiduously applied, and the tympanitic distention gradually giving way to a feeling of doughy softness, seemingly limited to the abdominal wall. There was not, at that time, any doubt in my mind as to the typhoid character of the malady; but I was rendered uneasy by a steady emaciation, whose progress was visible from day to day, almost from the morning to the evening visit, and which was out of all proportion to the intensity of the fever and other symptoms. The pulse, too, continued good, being moderately forcible and full, and varying between 88 and 96 per minute. The treatment with quinine and opium, in small doses was continued, and the constipation which had now become a persistent symptom was relieved by simple enemata.

[1] Read before the Cincinnati Medical Society, October 5, 1885.

On August 2d in the evening the temperature reached 103°. The boy had been doing fairly well; he received an unexpected visit from his father, was encouraged to talk rather freely, and owing to the presence of a number of visitors, a lively general conversation was carried on in the sick-room, in which he joined. The fever remained high for the next three days, there being no new development of any local symptoms, save a large area of pulsation over the abdominal aorta in the region of the cœliac axis, so that the impulse could be felt an inch and a half to the right of the median line down to the umbilicus, and about one inch to the left of the median line. Taken in connection with the rise of temperature, and my hypothesis as to the cause, it seemed not unlikely that infiltration, and possibly suppuration of the retro-peritoneal glands was going on, and I was in great measure strengthened in this belief when at 4 P.M., August 5th, he had a slight rigor, followed by fever and profuse perspiration. He was seen that evening by Drs. Mackenzie and Dandridge, in consultation, and I laid before them a proposition to make an exploratory incision for the purpose of giving exit to any pus that might be forming in or very near the peritoneal cavity. The plan was negatived—happily so, I think, for the operation would have been made to bear the opprobrium of the boy's death. The pulse now became very feeble, irregular, 120 per minute, the respiration 28, alæ nasi moving on inspiration, the face wore a more pinched expression, and the strength was rapidly declining. There was retention of urine, so that the catheter had to be employed, the urine, being dark in color, slightly alkaline, and, owing to the great heat, undergoing ammoniacal fermentation almost as soon as drawn; there was an abundant deposit of phosphates, no albumen

August 6th, at 4 P.M., had a very severe chill, so that he shook the bed, lasting fifteen minutes, followed again by profuse sweating. Owing to the cardiac feebleness he was ordered tr. digitalis, gtt. xx.; ether sulph., gtt. xxx.; spts. frumenti, ℥ ij., every four hours. The second chill occurred, notwithstanding a dose of quin. sulph., gtt. xx., taken at 5 A.M. After the chill, the temperature, which had reached its highest point at 4 A.M., being then 104.6°, and had gradually fallen until it marked 101.3° at noon, rose again to 104°. The chill was not again repeated, the patient suffering occasionally from slight rigors, and the temperature remained high for two or three days. There was again great abdominal distention, gurgling was elicited by very light pressure over the whole surface, and pain complained of on pressure in the right iliac, right lumbar, and umbilical regions. The pulsation in the latter region now became more distinct, and on August 9th, the tympanites having subsided, a hard indurated, irregularly rounded mass was felt through the abdominal parietes. Auscultation over this mass revealed a distinct double murmur, synchronous with the heart-sounds, and similar to the murmur obtained by making firm pressure with the stethoscope over the carotid or subclavian artery. It was interpreted to signify that pressure was being made either on the aorta itself or on the cœliac axis by a packet of enlarged glands. But my views as to the cause of this enlargement had undergone considerable modification by many of the anomalous symptoms presented, and Dr. Mackenzie, who had hesitated about accepting the diagnosis of typhoid fever, now agreed with me in regarding it as a case of acute miliary tuberculosis, limited to the peritoneal cavity. The most careful examination of the heart and lungs revealed nothing abnormal.

August 10th.—The patient passed the best day he has known in several weeks. The morning temperature was 99°, the pulse 84, the respiration 20 and fairly regular, his manner was more lively and cheerful, though he had been quietly hopeful from the first, and he expressed himself as feeling very hungry. It was apparent that he was becoming constantly weaker and that the emaciation was progressing. He moved freely from side to side, was able to pass urine voluntarily, and complained of no pain except on pressure over the umbilicus. The apparent improvement was so marked that his family became extremely hopeful of his ultimate recovery.

August 11th.—He passed an extremely restless night. Physical examination this morning reveals a loud, very distinct systolic murmur, heard with considerable intensity over the whole præcordial region, and having a musical, distinctly whistling character, very much like the sound produced by driving a whip forcibly through the air. The heart's action was rather feeble, but tumultuous, and the pulse small and easily compressible. The murmur over the tumor in the abdomen was now systolic, having lost its double character. It was not in any way related to the cardiac murmur, which had developed later, as there was between the two a distinct area in which no abnormal sound could be heard. The stomach, for the first time in the entire course of his illness, became troublesome, and all liquids taken were rejected, with large quantities of bile. There was not much retching, vomiting taking place without any effort. Bowels constipated.

August 12th.—Vomiting controlled by small doses of calomel and camphor. Perspiring very freely. Endocardial murmur not as loud as yesterday; has more the character of an ordinary murmur. Appetite good. Is losing ground perceptibly. Temperature, 102.6°; pulse 120, very small and feeble.

August 13th.—Countenance this morning has Hippocratic type. Had slight chill yesterday afternoon. Intellect perfectly clear. Some pain about the umbilicus, where the indurated mass can be more clearly felt, partly on account of its enlargement, partly because of the increasing emaciation. Abdomen neither tympanitic nor retracted; still has a certain boggy feel.

August 14th.—Died this morning at 8 A.M., having retained consciousness to within an hour or two of the end. An autopsy was not obtained, and yet I have not much hesitation in affirming the case to have been one either of acute tuberculosis or of pyæmic absorption from some focus in the peritoneal cavity. Typhoid can be eliminated, I think, because of the absolute freedom from all cerebral disturbance, because of the peculiarities of the temperature in the last week, because of the persistent constipation, because of the clean, moist tongue and the absence of any signs of feebleness or prostration, other than could readily be accounted for by the gradual muscular waste. We use the term typhoid, as applied to other diseases, to characterize the presence of these symptoms, probably of all nervous origin; and the absence of all of these, irrespective of the temperature or condition of the bowels, seems sufficient warrant to exclude this affection. It may be objected that the endocarditis, developing in the last few days, would be a very unusual complication of acute tuberculosis.

It may be a rare complication, certainly, but that this is not sufficient reason for altering the diagnosis, is in a measure demonstrated by the occasional reports of cases of supposed typhoid complicated by parotitis, the autopsy alone revealing the true nature of the case. Such cases are reported by Senator (*Berl. kl. Wochensch.*, 1881) and Samter (*Berl. kl. Wochensch.*, 1884). The case of Senator is particularly interesting, the patient's history containing many points of similarity with the case here reported, the tongue being moist, the intellect perfectly clear, epistaxis occurring in the first week, and abdominal distention and tympanites being prominent symptoms in the second and third weeks. A suppurative parotitis appeared two days before the fatal termination, and the clinical diagnosis, made by so careful and experienced an authority as Senator himself, was typhoid fever. It remained for the autopsy to demonstrate this plausible error. The fact of the patient's having had an attack of typhoid fever three years before could not militate against the diagnosis, as Senator and others had met with cases in which a second attack

undoubtedly occurred. There was a certain anomaly in the temperature curve, the morning remissions being very marked, but this was not considered sufficient in itself to cause a serious doubt, and when finally, after repeated occurrence of epistaxis, suppurative parotitis set in, a complication recognized as a comparatively frequent attendant of enteric fever, there seemed no longer any room for doubt or hesitation, the prognosis at the same time being thereby made very unfavorable. The latter was confirmed all too soon, and the autopsy revealed miliary tuberculosis of the lungs, caseous bronchial glands, miliary tuberculosis of the enlarged spleen, liver, and both kidneys. There were not the slightest indications, either of the old attack of typhoid, or of any more recent trouble in the intestines. The difficulty of diagnosis in this case was enhanced by the early appearance of the characteristic roseolar spots, a symptom of the greatest rarity in acute miliary tuberculosis; in our own case the external application of hot poultices and turpentine stupes would have made the very recognition of the rose-colored spots impossible, had they been present. Senator, in this very valuable and explicit contribution, refers to the comparative frequency of acute miliary tuberculosis in individuals who up to that time had been in apparently good health, thus rendering the diagnosis much more difficult. He refers to other symptoms of supposd diagnostic value, as *distention of the abdomen, dicrotic pulse, partial deafness, tendency to hemorrhages, particularly epistaxis,* in typhoid fever; and *cyanosis, dyspnœa, irregularity of the pulse, and an increase in frequency of the latter out of all proportion to the rise of temperature,* in tuberculosis. But his own case shows the unreliability of many of these symptoms, though he says that of all published cases he knows of only one other in which epistaxis occurred during miliary tuberculosis, and he concludes his paper by affirming the impossibility of correctly diagnosing such a case as his own.

In the case which forms the subject of this paper there was another symptom, which seems to me of special diagnostic value—a rapid and progressive emaciation, very decided, disproportionate to the amount of fever and general constitutional disturbance, and steadily increasing despite a very fair amount of nourishment consumed, and apparently assimilated, daily. This, in conjunction with the other facts which would not well comport with the hypothesis of typhoid, decided the diagnosis. It is true, the crucial test of its correctness, the autopsy, was denied us; yet it seems to me that there can be no question as to the exclusion of typhoid fever. There yet remains to be explained the acute endocarditis. Samter, in the article referred to (*Berl. kl. Wochensch.*, 1884), believes that there is in some cases of acute miliary tuberculosis a double infection, a septic and specifically tubercular one, anatomically distinct from each other, as evidenced by the presence of the bacilli of tubercle and micrococci, and it is possible that the septic element may have manifested itself here in the development of the endocarditis.

Perhaps it may be stated in objection to the diagnosis that typhoid and acute miliary tuberculosis may be simultaneously present; of such an association there are, according to Senator, but three authentic cases on record, and it is not necessary to seek for so distant a hypothesis, when the clinical history is sufficiently explained by assuming the case to have been one of acute tuberculosis. There is one point in connection with the history which has been the subject of some speculation with me, though it must be a fruitless kind of inquiry, and that is whether or no the permission to get up on the ninth day was in any way responsible for the farther development of the symptoms. It seemed unreasonable to confine the patient after his having passed three days with scarcely a trace of fever and with entire freedom from pain; and, though he transgressed the limits of indulgence, I cannot make this the cause of the farther and fatal course of the disease. I doubt whether all my hearers will be willing to agree in the diagnosis, even when I mention the fact, made known to me only upon persistent inquiry after the unfortunate death of the young man, that there existed a decided hereditary tendency to tubercular trouble on the mother's side, but if the paper shall have succeeded in calling attention to the close similarity of the two diseases, even to what have been considered as almost pathognomonic symptoms, a resemblance extending from the beginning to the close of the attack, it will have accomplished all that I had hoped for it. I append the post-mortem notes of three cases in which the autopsy was made by myself and in which the tubercular deposit was confined almost entirely to the abdomen.

No. 1, June 19, 1885.—A. N——, aged twenty-five, body that of a white woman slightly below average height, fairly developed, poorly nourished. Autopsy nineteen hours after death, rigor mortis slight. On puncturing the diaphragm, after the usual median incision had been made, air or gas escaped from the left pleura with a hissing sound. The left pleura found thickened, the result of chronic inflammations. The left lung was much compressed, so that it occupied about one-third of its normal volume. Its substance was solidified and covered with a thick layer of lymph. No point could be discovered by which air had entered the pleural cavity. The right lung was œdematous; small, indurated deposits were found in its lower lobe, but no signs of caseation.

The liver, spleen, stomach, intestines, uterus, and bladder were everywhere covered with tubercular deposits, which had led to the formation of many adhesions between neighboring viscera. The parietal peritoneum was covered with similar deposits. Uterus, slightly enlarged, contained at the fundus a small, hard, submucous fibroid. Fallopian tubes were filled with caseous material, probably the result of a chronic salpingitis. Retro-peritoneal glands and thoracic duct were enlarged and thickened from tubercular and caseous masses. Pancreas contained along its surface a number of small caseous deposits.

No ulcers were found in the intestines, nor were there marked changes in any of the viscera.

Cause of death.—Tubercular peritonitis, probably secondary to caseation from chronic salpingitis.

No. 2, July 28, 1885.—A. H——, body that of a colored boy about twenty years of age, well developed, poorly nourished, slightly below average size. Autopsy ten hours after death, rigor mortis absent. Extreme emaciation everywhere apparent. On opening the abdomen all the viscera were found firmly adherent to one another by bands of fibroid adhesions, which evidently had their point of departure in a chronic tubercular process associated with tubercular ulceration of the intestines. Fully one-half the abdominal cavity was occupied by a large packet of caseous glands, which projected from the median line over each side of the spinal column, and were intimately adherent to one another and to neighboring parts. All the abdominal viscera were covered with small caseous tumors adherent to the capsule. The intestines were in many places so firmly matted together that it was impossible to separate the adhesions without tearing the intestinal wall. Bands of adventitious tissue ran across the wall of the cavity, intimately blended with loops of intestines.

In two or three places ulcers of the intestine had extended down to the peritoneal layer. Spleen, amyloid; liver, cirrhotic; kidneys, fatty; lungs presented characteristic changes incident to general tuberculosis, with one or two cavities; brain, œdematous.

Cause of death.—General tuberculosis, mainly in peritoneum.

No. 3, June 21, 1885.—A. P——, aged sixty, body that of a white woman, well developed, fairly nourished, of average size. Autopsy fourteen hours after death, rigor mortis moderate. On making the usual median in-

cision it was found that the abdominal viscera were all matted together by tolerably firm, comparatively recent adhesions. Thorax slightly distended, bulging forward owing to the emphysematous condition of the lungs, which organs, aside from the emphysema, were normal. Heart soft and flabby. Liver fatty, slightly enlarged, its peritoneal surface (as, indeed, the entire peritoneal surface) was densely strewn with gray miliary tubercles. Kidneys enlarged, cortex gray and slightly fatty, capsule adherent, leaving a faintly roughened surface when detached, evidently the early stage of cirrhotic kidneys. Stomach normal, covered with tubercles. Intestines showed no ulcerations, contained small quantities of thick mucus and light-colored fecal matter. Fallopian tubes were both dilated with clear fluid, presenting a symmetrical condition of hydro-salpinx. Endometrium was congested and swollen. Retro-peritoneal glands slightly enlarged, but not caseous. Brain not examined. There was noted a slight ulceration of the right cornea.

Cause of death.—Tubercular peritonitis. No focus of caseation was discovered.

As a matter of very considerable interest, and one calling for farther careful study, I append the following short extracts from the original article of Brunniche, published in the *Gazette Hebdomadaire*, 1875, No. 3, to show the value of the peculiarities of temperature in deciding a doubtful case :

Of 52 patients dying of phthisis, in whose cases a careful record of the temperature was kept, the inverse type (morning exacerbation with evening remission) was noted in 33. The inverse type seemed to bear no relation to the degree of fever, to any hyperpyrexia, to colliquative or night sweats, nor to any phenomenon revealed by auscultation, but it was found on post-mortem examination to have occurred much more frequently in cases that became *tubercular*. In phthisical cases, without the presence of miliary tubercle, the inverse type was present in only twenty-five per cent ; in those in which tubercles had developed, the history showed this peculiarity of the temperature in eighty-six per cent. *Brunniche* regards miliary tubercle as a sort of inoculation through the agency of caseous matter contained in the lymphatic glands, and thinks himself justified in concluding from his experience that the inverse type is probably very often a sign of miliary tubercular infection.

In a series of 41 cases of phthisis, there were, first, 13 cases without tubercular infection, and in these the inverse type was noted in 38.4 per cent ; second, 28 cases with tubercular nodules in the lungs and other organs, and the inverse type was present in these in 70.87 per cent.

In 10 cases of primary acute miliary tuberculosis, without any accompanying phthisis, the inverse type of temperature was present in ninety per cent.

In another series of 17 cases of primary acute miliary tuberculosis 15 presented this peculiar range.

There was also a predominant tendency to the inverse type in female patients as compared with those of the male sex ; probably, Brunniche thinks, owing to a greater predisposition of females to tuberculosis.

THE DEATH OF A MEDICAL POET.—Our French exchanges announce the death of Dr. Camuset, of Paris, and some of them lament in him the loss of a talented medical poet. The *Cincinnati Lancet and Clinic* has taken the trouble to translate two of his sonnets, of which the following is a specimen :

"THE CORN.

"I'm a poor little corn, and protest
'Gainst the shoemaker raising a blister.
'Tis the fashionable boot I detest.
Heaven help dear phalanges ! my sister.

"The chiropodist doeth his best,
He wields a sharp knife, the professor.
Short is his triumph, from pain there's no rest,
I'm renewed, spite the iron aggressor."

FURTHER REPORT ON OXYGEN AS A THERAPEUTIC AGENT.[1]

BY SAMUEL S. WALLIAN, A.M., M.D.,
BLOOMINGDALE, N. Y.

IN again reverting to a subject upon which I have already written several addresses and journal articles, no apology is necessary, since I am a confirmed believer in, and the prevailing temper of the profession generously tolerates, if it does not boldly encourage, special lines of medical inquiry. It is by confining our chief efforts to a single subject of investigation that each is enabled to contribute valuable results to the general stock of professional knowledge.

Since the publication of my first paper upon this subject, I have further pursued the study of the therapeutic possibilities of oxygen and its congeners, have received hundreds of letters of inquiry from practitioners in various parts of the country, and have corresponded extensively on the subject. I have also published several articles in THE MEDICAL RECORD and elsewhere, some of which have been reprinted in pamphlet form, and may be had on application.

Papers and reports bearing upon this subject, have also, from time to time, appeared in various foreign as well as American medical journals.

Loyssel, in the *Journal de Médecine de Bruxelles*, August, 1884, reports results of extensive experiments with the pure gas. During the year I have received a copy of a work published in 1870, at Calcutta, by J. E. Purdon, Staff Assistant Surgeon in the English Army operating in the Indies. It is a quaintly printed octavo of 120 pages, entitled : "Cholera ; and Efforts toward Framing an Equilibrium Theory of Disease."

Dr. Purdon labors with really ingenious plausibility to show that oxygen, and its actinic state, ozone, by their presence or absence are important, if not principal, factors in the origin, dissemination, and antagonism of cholera and other epidemic and zymotic diseases.

Loyssel, in the paper referred to, formulates the following conclusions :

1. In certain cases of poisoning, viz., by chloroform, ether, chloral, opium, sulphide of hydrogen, carbonic oxide and hydrocyanic acid, oxygen is the only means of preserving life after all other means have failed.

2. Its presence in the operating-room would be an infallible safeguard against fatal accidents from the use of anæsthetics. It promptly restores sensibility and eliminates narcosis in all such cases.

3. It offers the best prospects for success in asphyxia from strangulation, drowning, poisonous gases, etc., as also in cases of suspended vitality in the new-born.

4. It will almost surely sustain life in all cases in which respiration has not entirely ceased, even if the intervals between inspirations be very great, provided it be persistently exhibited.

5. If cardiac and respiratory action have been absent for but a short time, resuscitation is often possible through the use of oxygen ; and this agent should be perseveringly used in all such cases, even when appearances indicate that all efforts will prove useless. Cases have been frequently reported of drowned persons and apparently still-born children being fairly raised from the dead by persistent endeavors with oxygen.

6. There is no contraindication of the gas in any case of asphyxia.

7. The gas can be respired in notable quantities without the slightest injury.

Dr. Holstein, in the *Gazette Médicale de Paris*, asserts that oxygen has marked power in enfeebling or inhibiting exaggerated reflexes.

Professor Lashkevitch, of St. Petersburg, reiterates this assertion, and a this suggestion, Dr. Favr, of Kharkov

[1] Read before the Medical Association of Northern New York, at Malone, October 6, 1885.

(reported in *Vratch*, No. 13, 1885), resorted to oxygen inhalations in two cases of puerperal eclampsia, and his efforts were followed by prompt and brilliant results.

The first was that of a seamstress, aged nineteen, who was brought to the hospital in an unconscious state, cyanotic, with stertorous breathing, the convulsive paroxysms being very frequent, and each preceded by a uterine contraction. Warm baths, wet packings, and enemata had been thoroughly tried without affording any relief. Chloral hydrate failed to mitigate the paroxysms, and even chloroform inhalations gave but slight and transient relief. Oxygen was then resorted to as a forlorn hope. Within five minutes from the first inhalation of the gas the patient recovered consciousness sufficiently to call for a glass of water, the pulse fell from 120 to 90 per minute, and a tranquil sleep of two hours' duration intervened. At the end of this period uterine contractions recurred, without exciting an eclamptic seizure; but on suspending the oxygen inhalation the paroxysms soon returned. A fresh supply of the remedy brought each paroxysm to a speedy termination and quiet sleep followed each resumption of oxygen inhalation. At this juncture, the os being not yet dilated, Barnes' dilators were used, the membranes punctured, and the delivery completed without further accident. The patient was discharged on the nineteenth day after confinement, in a very comfortable condition.

The second patient, a primipara, aged eighteen, had two paroxysms of eclampsia, *post partum*, twenty minutes apart, and lasting twelve minutes each, the patient remaining unconscious in the interval. On the administration of oxygen consciousness at once returned. Four more paroxysms followed, but they were very much milder, and separated by intervals of entire consciousness and perfect comfort. This patient made a rapid and satisfactory recovery.

Dr. Favr concludes his paper by expressing his enthusiastic hope that further tests will so corroborate these results that, in the near future, oxygen-gasometers will become a common and indispensable feature of all lying-in hospitals.

Among the newer preparations brought forward, recently, as related to the oxygen family, Professor Beck stands godfather to one called by the rather questionable name *Ozonine*. It is a liquid, depending wholly upon ozone, or actinic oxygen, for its medicinal virtues, and was recently discussed at a meeting of the Biological Society of Paris (*Repertoire de Pharmacie et Journal de Chimie Médicale*, 1, 1885).

Of this preparation—the details of its manufacture not being given—Onimus, of Paris, declares that as a disinfectant it is scarcely less prompt or efficient than ozone in a gaseous state.

Brand, of Toulon, used this drug with marked success in small-pox and in cholera.

Griol and Long assert that for putrid and zymotic diseases and conditions, in hospital practice, this preparation, by constantly liberating ozone, affords to nurses, physicians, and attendants, certain and safe immunity from infection.

Its application to flesh in an advanced state of decomposition, and to putrid eggs, promptly corrected all odor and appearance of putrefaction.

It blackens metallic silver, changes arsenite of potash into arseniate, and gives the usual reactions of ozone with the test-papers of Schönbein and Houzeau, as also with thallium paper.

Thus as an antiseptic, antizymotic, antiputrefactive, and disinfectant, this preparation may, in time, supersede the entire list now in use.

Following in the wake of the above, a Boston firm has offered a preparation called *ozone water* (*Aqua Ozonata conc.*), which is claimed to be an efficient form in which to exhibit ozone, both as a disinfectant and for internal administration. Although I have used this article to some extent it has not met my expectations; but my experience with it does not warrant any intelligent or final decision as to its merits.

Of *hydrogen dioxide*, H_2O_2, commonly called peroxide of hydrogen, and by some inaptly called "oxygenated water," I have spoken in former papers. Among recent experimenters with this compound, Hensel, a German chemist of note, has given it careful study, and has published the results in a brochure which has been translated into English by Professor W. A. Dayton, assisted by Mr. Paul Trentler, of New York. The translation has not yet appeared in print, but it is to be hoped it will ere long be rendered available to the American profession.

According to the interesting table of Professor Miguel, peroxide of hydrogen stands third on the list, as to potency in preventing putrefaction, the binoxide of mercury and iodide of silver alone excelling it in this direction. Since it is entirely non-irritant, non-toxic, and almost as bland in use as simple water, it ought to supplant all the toxic and irritant agents now in use in surgery for the purposes named.

It is also an accurate and reliable test for pus in urine. By adding a solution of the peroxide to the suspected sample, brisk effervescence at once ensues, if pus be present.

Dujardin-Beaumetz has recently given the results of some experiments with this drug, internally exhibited, in cases of severe anorexia, in diabetes mellitus, and in polydipsia. In the first, return of appetite was readily accomplished without causing any gastralgia or other untoward symptoms. In the cases of diabetes the results were negative. In a case of polydipsia, in which twenty-eight litres of urine were voided daily, the improvement was very prompt.

In the *New York Medical Journal* of April 25, 1885, Dr. Dayton, whose joint translation of Hensel's work has been referred to, gives a summary of his experiences with peroxide of hydrogen. Having had his attention called to it by Hensel's enthusiastic description of its properties, he essayed its use both topically—chiefly in spray—and internally, in solution, in severe cases of throat, nose, and ear disease, "complicated with tubercular infiltration of the lungs." Dr. Dayton concludes his paper, which will well repay perusal by all who are interested in the subject, by asserting, "that the peroxide of hydrogen has a future among the most trusted resources in the materia medica, I have no doubt. It is a potent deodorizer, it is an eligible antiseptic (in [?] and out of the circulation), and it is an effective remedy in a large class of diseases in which mucous-membrane tissue is chiefly involved. For cleansing purposes it has no equal in any known agent. In operations on mucous membrane, where the secretions and hemorrhage often embarrass the surgeon, the use of a strong solution of the peroxide (twelve per cent.) facilitates progress by decolorizing the blood and by its cleansing, styptic properties."

Dr. F. Allport, of Minneapolis, in a recent number of the *American Journal of Ophthalmology*, gives a strikingly similar report of experiments with this drug, used in the same class of diseases. He, however, evidently writes, as do most recent observers, in utter unconsciousness of work done and reports published by confrères and predecessors; hence encumbering his brief paper with a reiteration of the now somewhat trite history of the original discovery, etc., of the compound.

Certain scientists are now asserting that the immunity from pulmonary and other degenerative diseases, and the general healthfulness enjoyed by those who dwell in the immediate vicinity of pine forests, is largely due to the constant presence of peroxide of hydrogen in the vapor of the atmosphere.

These pine districts have, on the same account, been noticed to have a remarkably beneficial effect on the voice.

Heretofore it has been the custom to ascribe these effects to ozone.

Nitrogen monoxide.—On the therapeutic use of this

gas I have received nothing new from foreign sources since the publication of the several papers already referred to. If anything of importance concerning it has appeared, at home or abroad, it has escaped my notice. While its importance as an additional member of the oxygen group cannot be called in question, no one of the foregoing authorities makes the slightest allusion to this compound, which must eventually be recognized as an essential adjunct to every comprehensive trial of the so-called "oxygen treatment."

This gas is the "nitrous oxide" of the old nomenclature, is more generally known by this name, and is represented by the formula N_2O. It is the basis of the "well-kept secret," for years so successfully vaunted by polished and oily-tongued quacks as "Compound Oxygen;" and, it must be admitted, that in connection with some wholesome hygienic rules persistently inculcated, these advertising professional outlaws have really performed some therapeutic, as well as *moral*, wonders by its aid. While no honorable member of the profession can respect their pusillanimous claims as "discoverers" of a "new compound of oxygen," or can do otherwise than feel contempt for their cheap and vapid "home-treatment" swindle, composed, as has been reliably shown, of inert solutions of the nitrates of lead and ammonium, my now somewhat extensive experience compels me to esteem nitrogen monoxide an essential adjunct in nearly all instances where oxygen is indicated. When I say that I scarcely ever treat a single chronic case without its aid, this admission is as strong evidence as I can adduce of my personal estimate of its value as a potent and essential modifier of pure oxygen.

Here, again, American enterprise has lagged, and foreign investigators have given us most of the accurate knowledge we possess concerning this gas. Its fame and excellence as a temporary anæsthetic have generally overshadowed any claims it has as a therapeutic agent. In fact, a fairly inexcusable degree of ignorance and misapprehension exists, on the part of the profession, concerning the chemical nature and physiological possibilities of nitrous oxide gas. Even by our foremost chemists it is assumed that anæsthesia produced by it is a true narcosis, a genuine asphyxia. Thus Dr. Squibb says ("Transactions New York State Medical Society, 1871," p. 201): "A patient may, doubtless, be as effectually drowned by nitrous oxide as by water, and the resuscitation from partial drowning by it involves the same principle of treatment."

This assertion is a concise statement of the average estimate of the physiological relations of this gas.

With all deference to the generally dispassionate and proverbially accurate opinion of the eminent scientist who utters it, this estimate is wide of the truth, and utterly misleading. All modern dentists can refute it by daily experience, thousands of their patrons inhaling it, to the extent of physiological saturation, as it were, without suffering from any of the usual sequelæ of asphyxia. On the contrary, the usually observed effects following its excessive exhibition, aside from the temporary anæsthesia produced, are those of pleasurable exhilaration and restfulness. There are no evidences that the blood of subjects caused to inhale even excessive quantities of this gas is poisoned, as by carbon dioxide or carbonic acid; therefore it remains to be shown that the nerve-centres are momentarily benumbed in some other way than by the toxic influence of this latter agent, or the non-aeration of the blood.

I have not hitherto found time, nor am I aware that any one has yet attempted to perform the necessary physiological test-experiments on the lower animals, which can evidently be made to set forever at rest this scientifically disputed but, empirically, already settled question.

Dr. Ziegler long ago insisted that this gas, being almost as good a supporter of combustion as pure oxygen, is capable, when inhaled into the lungs, of supplying oxygen to the animal system. My clinical experience with it certainly corroborates this estimate.

If it were, in fact, an asphyxiating agent, as so loosely taught, it is evident that its exhibition in unstinted quantities to literally hundreds of thousands of dental patients every year, would be far more frequently attended by disastrous sequelæ. As it is, the danger of a fatal result, even after the most careless and excessive exhibitions of it, in dental practice, to patients representing every possible degree of vital stamina, is immeasurably less than that represented by the buncombe lightning risk appended to some forms of fire insurance policies. It is practically nil, since an equal number of deaths would occur, in the same practice, from nervous shock, accidental anomalies—almost from old age!

To refute and correct this antiquated misapprehension, it is only necessary to quote an outline of its chemical nature and physiological properties from any authentic hand-book of chemistry, viz.:

N_2O is a colorless, almost inodorous gas, of distinctly sweet taste. Its specific gravity is 1.525, a litre of it weighing 1.97,172 gramme; 100 cubic inches weighing 47.29 grains. It supports the combustion of a taper or a piece of phosphorus with almost as much energy as pure oxygen; it is easily distinguished, however, from that gas by its solubility in cold water, which dissolves nearly its own volume. Mixed with an equal volume of hydrogen, and fired by the electric spark in the endosmometer, it explodes with violence, and liberates its own measure of nitrogen. Every two volumes of the gas must consequently contain two volumes of nitrogen and one volume of oxygen, the whole condensed or contracted one-third —a constitution resembling that of the vapor of water. *If quite pure* (the italics are mine), or merely mixed with atmospheric air, it may be respired for a short time without danger or inconvenience. The effect is very transient, and is not followed by depression (Fownes).

Those who have witnessed fatal cases of asphyxia from respiring "choke-damp," or any other asphyxiating gas, need not be reminded that the rapidly fatal toxæmia of the latter agents, with the accompanying cyanosis, œdema, and distortions, is quite unlike any of the foregoing phenomena attending the use of nitrous oxide.

Of the millions of instances of its inhalation, even to complete saturation of the system, for dental and surgical purposes, how many have proved fatal, or even temporarily injurious? Surely not so many as have dropped dead while passing along the street, or sitting at table, or as have been smitten by lightning, during the same time.

Can such a record attach to so potent an asphyxiator as Professor Squibb would have us think is found in gaseous nitrogen monoxide?

Reverting to the several authorities briefly cited, it will be seen that, little by little, the meagre literature bearing upon the therapeutic possibilities of the oxygen group is being added to, and, in time, we shall not be without cumulative, as well as conclusive evidence, of a clinical character, in connection with this interesting subject

The most serious drawback or hindrance to the rapid progress of this so-called oxygen treatment, which may be aptly styled the principal branch of natural therapeutics, based as it is on reason, physiology, and clinical success, lies in the fact that, with our present facilities, or lack of facilities, its extensive clinical exhibition involves more time, care, and cumbersome apparatus than a majority of practitioners can devote to it. It is for lack of the *required patience and painstaking that so many experiments have failed, and will continue to fail, of satisfactory results.*

But facilities are being constantly increased and improved. Oxygen can now be had, condensed in rather unwieldy but portable iron flasks, containing one hundred and two hundred gallons each. Nitrogen monoxide has for years been available, in liquid form, in flasks of

readily portable size; and several manufacturers are now giving us the peroxide of hydrogen in convenient form and of unexceptionable quality. The liquefaction of oxygen is also, at last, an accomplished fact; M. Cailletet having recently perfected a process and an apparatus of very simple character by which this result is easily attained. The process is thus sketched: Ethylene is brought to the boiling-point in open vessels, producing a degree of cold represented by -123° C., or -253.4° F. At this point oxygen assumes a liquid form, and may be stored in strong flasks. It ought not to be long ere we can procure this element at the counter of any well-stocked pharmacy in suitable vehicles for ready transportation and instant use.

A French mineral-water firm has begun to supply Paris dinner-tables with distilled water charged with oxygen. The beverage is mildly exhilarating and likely to become popular. The idea was suggested by the favorable report of Dujardin-Beaumetz to the Société Thérapeutique already referred to.

I shall be glad to assist in an advertising boom for the first American firm which shall have the enterprise to follow suit.

As an offset to the charge of enthusiasm and hobby-riding it may be pertinent to reiterate a few well-known physiological and vital aphorisms:

"Oxygen is the sustaining principle of animal life and of all the ordinary phenomena of combustion.

"The process of respiration in animals is an effect of the same nature as common combustion. The blood contains substances which slowly burn by the aid of the oxygen thus introduced into the system. When this action ceases, life becomes extinct" (Fownes).

The biblical account of creation says, God breathed into his nostrils the breath of life (oxygen) and man became a living soul. Nor can animal life be maintained for a single hour without it. The first gasp of the newborn is for oxygen, and this instinctive and involuntary struggle continues, without a moment's cessation, at every step of the journey, from the cradle of infancy to the ever-open portals of "that pale realm from whose bourne no traveller returns."

Nine-tenths of all the curable diseases with which the human race is afflicted are the direct results of deprivation; they are genuine *toxicoses*. Each individual nurses within his own breast the poisoned arrow which finally slays him. All the habits, fashions, and tendencies of our modern civilization lead to physiological robbery, physiological semi-asphyxia. The poor are "hovelled and hustled together, each sex like swine," while the rich vie with each other in devising costly mausoleums in which to immolate themselves.

The race, as a whole, ekes out but half its possible days on earth for want of better air—oxygen. All the processes of animal life go on by the aid of, and are incessantly presided over by, this omnipresent and well-nigh omnipotent element.

It may be urged that the natural atmosphere contains the true normal and sufficient proportion of oxygen for human consumption. Granted, but what proportion of the human race, living under civilized conditions, is fortunate enough to experience even an occasional breath of "natural atmosphere," untainted by floating germs, smoke, dust, or nauseating odors? Even on the frozen summits of the Alps, Tyndall detected floating motes and impalpable impurities; while the air of towns and cities is constantly loaded with noxious, though often invisible, organic and septic particles. The mansions of the wealthy residents afford no immunity. The heavy carpets and soft upholstery furnish lurking lodgement for clouds of dust-particles, which every movement of occupants or air-currents sets afloat, to permeate every available cubic inch of the "natural atmosphere," in every room in the house. Even if those whose waning energies show the subtle but sure deterioration going on be temporarily sent to the mountains or on sea-voyages, they must spend much of their time in cramped and unventilated hotels or dwellings, or in the crowded cabins of noisome steamships, where no breath of "natural atmosphere" is ever tolerated.

Thus pages might be filled with apt and applicable illustrations from everyday life, to prove the necessity for, and adequacy of, an increased proportion of oxygen, in our efforts to overcome the disastrous results of evil influences and untoward surroundings which cannot be wholly escaped in any thickly settled community. Oxygen burns up waste, effete, and deleterious organic matters retained in the system, or taken into the lungs during respiration. It supplies to the blood and tissues one of the chief elements of nutrition. It dissolves and eliminates morbid deposits and infiltrations. It is the one purifier of the blood, *par excellence*. Hence, it is available in nearly every form of chronic disease, and in many acute conditions.

True, there are yet difficulties in the way of its general use, but there is no reason why enterprising practitioners, who are not already too severely overworked, or who are not too shiftless or indolent to incur the necessary preparation and painstaking, should long be without facilities with which to avail themselves of this potent therapeutic agent. Its use has long enough been surrendered to advertising quacks. *It is time the regular profession rescued it from the smirch of charlatanry which has, to some extent, heretofore attached to it.*

Cases Treated.—Continuing my numbers from previously published reports, I proceed with

Case X.—Mrs. S. C——, aged forty-three; married; the mother of four children, the youngest nine. In October, 1883, severe and repeated floodings came on, attributed by her to protracted overstrain, as a laundress, and to the approach of the menopause. The symptoms, however, were quite similar to those of an induced abortion. Pelvic cellulitis supervened, and was followed by a large psoas abscess, which developed slowly, accompanied with intense suffering, including paroxysms of sciatica, hysteria, and an endless host of neurotic disturbances. Omitting details and non-essentials, the abscess was opened February 8, 1884, and discharged two quarts of very fetid pus. Evidently it should have been opened a few days earlier, in fact, during my temporary absence at the meeting of the State Medical Society of that year; but the neighboring practitioner, in whose hands I left the case, either doubted my diagnosis or hesitated to operate until my return.

Phlebitis of the larger veins of the right thigh supervened, probably of pyæmic origin, and the right knee-joint became the seat of severe inflammation. Contraction of the muscles and tendons ensued, with great deformity and total inability to use the limb. Anorexia and vomiting were persistent, the patient became much emaciated and greatly depressed, and altogether the case was discouraging.

As soon as it was feasible (April 27th) she was placed on oxygen treatment. ℞.: O, N_2O, and common air, āā 3 gallons, b.i.d.

May 10th.—General improvement is quite evident. The limb is less swollen and less painful, appetite returning. Treatment reduced to once daily.

May 20th.—Lameness very much better; she can get about the house without crutches and employs herself at housework.

June 10th.—Steadily gaining; does most of the housework for a family of eight. Appetite good. The limb is normal in size.

July 7th.—The improvement has steadily continued. Lameness nearly gone; appetite fairly voracious, and digestion excellent.

August 10th.—Lameness entirely gone. General health better than for some years, she having formerly suffered greatly from chronic dyspepsia. Treatment suspended. (Saw this patient September, 1885, rugged and well.)

Case XI.—D. F. A——, a railway engineer, aged

twenty-eight; single. Sent to me from a distant part of the State by his family physician. Father living, mother died of phthisis at thirty-eight. Says he has always been rugged with the exception of coughs and colds in winter. Admits that he formerly lived a little "fast," and that he had a touch of specific trouble several years ago. A homœopath "cured" two sores (chancres?) on the prepuce several times for him, the last one year ago. On the day following Easter, 1884, while at a circus, a profuse hæmoptysis occurred, suddenly and without warning. He was removed to the nearest physician's office, but bled so rapidly as to lose consciousness, and it was some hours before he rallied sufficiently to be carried home. Arrived here May 8, 1884.

May 9th.—Physical examination developed the following conditions: Figure slightly stooping; weight, 140; chest narrow and barrel-shaped; pulse, 110 and wanting in volume; temperature, 99.9°. On percussion find an area of dulness over the upper portion (not apex) of right lung, 5 × 5 inches. On forced expiration chest measures 30½ inches; on forced inspiration, 31¼ inches, showing an expansive capacity of only ¾ inch. Very loud tubular breathing over the right bronchus. Appetite capricious, the sight of an unsavory dish being sufficient to destroy it at any time.

Realizing the danger of recurring hemorrhages he is placed on a modified mixture of oxygen and nitrous oxide, well diluted with common air, and is cautioned against making any unusual effort when inspiring. Under this restriction he inhales four inspirations of 50 cubic inches each, b.i.d.

May 9th.—7.45 P.M.: pulse, 100. Four inspirations, as above, reduce the pulse to 92 *within two minutes.*

May 10th.—Pulse, 88, after treatment; respiration, 28.

May 11th.—5 P.M.: has just walked half a mile; pulse, before the inhalations, 117; after, 108.

Patient has heretofore been an inveterate smoker, consuming six or eight cigars of an evening. He is astonished to find his appetite for the weed entirely gone, and attributes it to three days' use of oxygen. As I have not before observed this result, further tests are necessary before announcing oxygen as a panacea for the tobacco habit! Dosage, 2 gallons, b.i.d.

May 14th.—Pulse, before treatment, 108; after, 102; and at the end of thirty minutes, 82.

May 16th.—Pulse, before inhaling, 81; after, 76.

May 18th.—Pulse, before treatment, 95; after, 85.

May 22d.—Chest measurements slightly increased, and he can now easily inspire 130 cubic inches at an effort. Can walk five or six miles at a stretch, without much fatigue, and feels very much encouraged. Eats and sleeps well. Pulse, before treatment, 82; after, 88; temperature, 99° F.

May 27th.—Pulse, before inhaling, 108; after, 94. To supply new material for the reparative processes evidently being inaugurated, I place him on Phillips' wheat phosphates, urging plenty of fresh beef, milk, mutton, eggs, and cream, with inunctions of cod-liver oil and glycerine three times a week, at night, to be followed in the morning by a hot bath, medicated with aqua ammonia and borax. He is also directed to imbibe half a pint of hot water before each meal, and at bedtime, daily.

May 31st.—Pulse, before treatment, 108; after three inspirations (five minutes), 96; temperature, 98.9°. There is a mild form of syphilide showing itself on the chest and back. Iodide of potash is added to his treatment, grs. x., t.i.d. Proportion of oxygen increased.

June 2d.—Pulse, before treatment, 84; after, 82; respiration, 24.

June 7th.—Before treatment, pulse 86; after four inspirations, 84. Chest now measures 30½ and 32 inches, a gain of ¾ inch in expanding capacity. Pulse-volume increasing. Dosage increased to three gallons, b.i.d.

June 20th.—Patient steadily gaining; can now inspire 150 cubic inches at an effort; chest measures on forced inspiration 32¼ inches. Dull area is smaller, and the vesicular murmur can be faintly heard over much of it. He can walk ten miles or more a day without fatigue. Treatment suspended, a pressure of summer travel requiring him to return to his post, promising to return in the fall. Weight, 145 pounds.

September 5th.—Returns, as per promise, weighing but 133 pounds. Has had no second hemorrhage. Pulse, 88; temperature, 98.8°. Chest measures 29¼ and 31 inches. Dry tubular breathing over right bronchus. The eruption is nearly gone.

October 1st.—Tubular breathing still distinct, but smoother. Area of dulness much smaller. Order Phillips' wheat phosphates with syr. pruni virg. and tr. nucis vom. Chest measures 29¾ and 31¾ inches. Temperature, 98.9°.

October 24th.—Dulness nearly gone. Eats and digests well. Pulse, 90, and quite full; temperature (8 P.M.), 99°.

November 27th.—Tubular breathing much less distinct. Pulse, 80; temperature, 99°; respiration, 20.

January 4, 1885.—Pulse, 93; temperature, 97.7°; respiration, 20.

February 19th.—Pulse, before inhaling, 98; after, 93.

March 10th.—Pulse, before inhaling, but after excitement, 104; thirty minutes later, after four inspirations, 96. Tubular breathing still audible, but vesicular murmur nearly as loud over the former dull area as elsewhere. Respiration still a little hurried—20 to 22—higher after exertion; but patient eats and sleeps well, weighs 144 pounds, and feels competent to return to his occupation. Treatment suspended. Have heard from this patient during the past summer, and always favorably.

Case XII.—S. A. C——, merchant, aged fifty-nine. Case of chronic rheumatism, severe dyspepsia, and slowly progressive locomotor ataxia. Oxygen treatment undertaken by means of a portable rubber bag, patient being confined to his bed, and completely helpless. Result of six weeks' treatment, gradual amelioration of all the symptoms. Locomotion became possible by the aid of a cane, and so remains at this writing.

Case XIII.—Mrs. S. A. M——, aged twenty-six. Disease, severe, chronic, gastric catarrh. Complete recovery, and a gain of fifteen pounds in body-weight, in six weeks.

Case XIV.—Mrs. H. A. E——, aged thirty. Case of unusually severe chronic constipation of ten years' standing. Family history shows phthisis, which has been both predicted and feared. Result of six weeks' treatment marked general benefit, which continues to date.

Case XV.—Mrs. W. M. A——, aged fifty-five. An extremely severe case of chronic eczema, complicated with hay-fever and an undoubted *specific* taint. The true nature of the case having been disguised in the beginning, treatment was undertaken and pressed for six weeks, when only moderate benefit being apparent, beyond the relief of the hay-fever and accompanying indigestion, further treatment was refused, the patient being advised to go to the Hot Springs of Arkansas.

Case XVI.—Dr. A. M——, aged fifty five, came to me suffering from aggravated dyspepsia, with persistent constipation and distressing insomnia. Weight, 130 pounds. Has had inflammatory rheumatism, and one sister died of phthisis. Was placed on active oxygen treatment with nourishing diet—no drugs whatever—and in three weeks gained five pounds in weight, and had an excellent appetite. Constipation relieved and digestion good. Sleeps soundly, and has climbed to the summit of a neighboring mountain, nearly five thousand feet above the sea-level. Is to continue the treatment at home.

Case XVII.—Mrs. H. W——, aged thirty-seven. Disease, chronic metro-peritonitis and subinvolution, with their usual train of feminine malconditions—dyspepsia, nervous prostration, hemicrania, cough, circumscribed "sore spot" under the left clavicle, etc. Percussion dulness over right apex, with exaggerated resonance over left.

Is placed upon O sixty per cent., N_2O thirty per cent., diluted ten per cent. Of this mixture, two gallons, b.i.d. The first inhalations produce marked sensations, viz., greatly accelerated respiration-rate, *without increasing the pulse-rate;* momentary partial anæsthesia; relief of prevailing migraine.

Mixture reduced to O twenty-five per cent., N_2O thirty-five per cent., diluted forty per cent., of which three gallons at a sitting, b.i.d.

At the end of one month's treatment she returns to her distant home, greatly relieved in every respect. Has gained a little in avoirdupois, more in vivacity; eats and sleeps well, climbs mountains, and has much less chest trouble. Has given up dying with "consumption," and has very little migraine.

Case XVIII.—Dr. K. J——, aged forty. Has been a chronic sufferer from indigestion and "neurasthenia." In one month the indigestion is a thing of the past. He eats the miscellaneous fare of a well-kept hotel with impunity. Has gained five pounds in weight, and says he feels "rested" and much stronger. Can hunt, fish, and climb mountains without great fatigue. Says he feels physically "renovated," and returns to his practice with zest.

Case XIX.—S. C. H——, aged thirty-seven; married; suffering from distressing dyspepsia, insomnia, and decline of virile power. After four weeks of active, but somewhat interrupted treatment, he declares himself a "new man." Was able to sleep soundly all night for the first time in two months after a single treatment—six inspirations. Now sleeps, eats, and digests well, and asserts that his virile powers are all that he could desire! In respect to this latter result, it was a surprise to me, but I have since noted the same revival in a very marked manner in a number of additional cases. The treatment has proved a prompt restorative to this function *in every case since observed*, in which loss of sexual appetite and power, *in either sex*, had been a marked feature.

Case XX.—Mrs. W. M. H——, aged forty-one; a good sample of the "lymph-albuminous" subject referred to by Bartholow. Very short of stature, but weighs one hundred and fifty pounds. Family history shows hereditary tendency to phthisis, rheumatism, and insanity! Suffers from frequent attacks of arthritis and daily recurring "stupid spells," in which it is impossible to keep her from indulging in a lethargic sleep, varying in duration from half an hour to three hours. Subject also to a "bilious" form of indigestion, with "sour stomach," periodic vomiting, and prostrating headaches.

In this case treatment was irregularly and spasmodically followed for several months, relieving the indigestion, and at the same time *reducing the body-weight ten pounds!*

She goes through the whole day without a "sleepy spell," the rheumatism yields with the aid of a little oil of wintergreen; no vomiting and no headaches. From being depressed and indifferent is now ambitious, active, and cheerful.

Two men were quarrelling. One of them threatened to shoot the other. The threatened man, in revival of an old piece of sarcasm, asked: "Where do you bury all your dead?" Just then an excited man drew the satirist aside, and said: "My gracious! you ought not to talk that way!" "Which way?" "Asking that man where he buries his dead." "Why?" "Because he is a physician."—*Ex.*

A New Treatment for Irreducible Hernia.—Dr. Burke reports a case in a man, sixty years of age, of a hernia, supposed to be irreducible, which was replaced during an attack of sneezing. He proposes the employment of snuff in similar cases in the hope that the violent sternutations will break up the adhesions and cause the bowel to slip back.

Clinical Department.

COCAINE IN CIRCUMCISION.

Dr. C. E. Bruce, of New York, communicates the following: The patient was a young man of twenty years, with an extreme phimosis, the prepuce extending about an inch beyond the glans penis and the orifice so small as scarcely to admit a probe. In urinating he had great difficulty, the foreskin would balloon up with the retained urine, which could only pass through the opening in the prepuce in a very small stream. He had prepared himself to be etherized, but consented to the use of cocaine when the probabilities where explained to him. Following the suggestion of Dr. J. L. Corning, "that the arrest of the circulation will prolong and intensify the anæsthesia"—and further, if possible, to secure a bloodless operation for its moral effect upon the patient, he being fully cognizant of his position and able to witness the surgical procedure—the penis was bandaged tightly with a narrow elastic tape, thoroughly compressing the member from the glans to the root. The bandage was then securely tied at the root of the penis, completely shutting off the circulation.

At once hypodermatic injections of about two minims each of a five per cent. solution of cocaine were made in the prepuce, both on its mucous and cutaneous surfaces. The entrance of the needle was scarcely perceptible to the patient—due no doubt, to the pressure of the elastic bandage—and not at all so after the first four or five injections had been made. A few minims were also placed in the meatus and underneath the prepuce, between it and the glans.

In about eight minutes the part was completely anæsthetized, the patient having experienced no pain or discomfort whatever. The foreskin was drawn forward evenly, so as to bring the mucous lining on an equal stretch with the skin, and clamped at the proper distance with long extension dressing forceps. The foreskin was then excised along the forceps, the patient *not having the slightest sensation*. The forceps were removed, when the edges were seen to be precisely and evenly matched in the entire circumference. There was no hemorrhage at all, the hands of the operators not even being soiled. The edges were then brought together by fifteen interrupted sutures, and the skin could then be easily slipped back of the glans.

The piercings of the needle were not felt in the least; at this point the elastic ligature was removed, when a slight hemorrhage followed (by oversight the frænal artery was not secured), but this at once ceased on the application of a firm bandage of iodoform and bichloride gauze with which the wound was dressed. The patient sat up immediately and dressed himself without assistance, went down stairs, and in fact resumed his ordinary avocation.

A few more points of interest:

The anæsthesia remained complete during the whole forty minutes of operation with no other injection of cocaine than the first. Pain did not recur on allowing the circulation to resume, nor for five hours afterward. There was no nervous shock, no disturbance of the stomach, no ill effects whatever. The amount of cocaine used was about two and one-half grains in fifty minims of water. Whether this prolongation of anæsthesia is due to the exsanguination of the tissues alone, thus allowing the contact of the anæsthetic with the sensory nerves to be prolonged and not have it washed out of the parts by the blood-current, and is a consequence of such prolonged contact, more or less profound; or whether it is due to a chemical change in nerve filaments, rendering the insensibility more protracted and hindering the rapid resumption of their sensitive functions, is a matter not yet settled.

Progress of Medical Science.

The Laws Regulating Continuous Extension as Applied to the Lower Limbs.—Dr. J. Hennequin has made an exhaustive study of the laws regulating the application of extension to the lower limbs. The following are the conclusions at which he has arrived (*American Journal of the Medical Sciences*): 1. Weights and heavy bodies of a determined value should be employed in extension, to the exclusion of elastic cords, in which the force of extension exerted is too variable and very frequently entirely inefficacious. 2. The apparatus of extension should have its point of resistance upon the skeleton of the mobile segment, in order that the force which it exerts may be of utility. 3. Extension, active force, counter-extension, passive force, are automatic, mechanical, or mixed. 4. Mechanical and mixed extension should be fixed upon that portion of the bone belonging to the less cumbrous, most mobile portion of the limb; counter-extension should be applied to that portion which is firmest and least mobile. 5. The method employed to produce fixation of both portions of the limb should be comfortable and such as will do no injury to the member, and should never extend beyond the limit of the segment upon which they have their points of resistance. 6. In solution of continuity, the point of fracture, and in arthritic disease, the interarticular line, is always the limit and centre of the forces applied for extension. 7. The force of traction must be proportionate to the resistance to be overcome and regulated, so as to render possible an estimate of its absolute power and of the effect produced. 8. The only traction of real value is that employed to overcome constant resistance; any force applied to overcome accidental resistance is entirely futile. 9. The inevitable resistance is represented by muscular tonicity and the elasticity of the teguments; accidental resistance has for its factors diverse elements, among which the principal ones are friction of the segments upon the bed and apparel, and the action of gravity upon the same segments resting upon an inclined plane. 10. The accidental resistance must be annulled or decreased to a minimum, and the mobile segment submitted to extension regulated in such a manner that the influence of gravity may be beneficial or its ill effect entirely obviated. 11. The application of extension and counter-extension to the segments of an injured limb is habitually mediate and rarely immediate; that is to say, that the forces applied generally take their points of resistance upon levers contiguous to those employed to produce motion or immobilization. 12. To direct and scientifically employ an apparatus for extension, it is necessary to know the value in force: 1, of the motor force; 2, of the force transmitted to the mobile segment; 3, of the resistance to be overcome; 4, of the loss experienced by the force of extension; for it is indispensable that this last factor retain, after all loss of power from all causes whatsoever, sufficient efficiency to overcome inevitable resistance. Upon this point the efficiency of the apparatus depends. 13. The value in weight of accidental resistance is impossible to be established, and it is therefore necessary to suppress it or to reduce it to such an extent that it may be disregarded. The inevitable resistance in an adult, whatever may be the development of the muscles or the location of the fracture, may be estimated at or between two and a half and nine pounds, and consequently the force applied to the bone of the movable segment, the efficient force should never exceed nine or be less than four and a half pounds. In the great majority of cases the weight required will be nearer the first extreme than the second. 14. Counter-extension, which should be rather mixed than purely automatic, and never exclusively mechanical, needs only to be employed with a force equal to the traction exerted upon the segment to be immobilized; if this is placed horizontally when the part rests upon a declined plane, the counter-extension bing of necessity exerted against both, the force of extension transmitted by the lax tissues which unite the segments, becomes absolutely imponderable. 15. In the majority of cases it is advisable not to permit the crural portion of the limb to remain completely free; a small trough will exercise direct pressure if it becomes necessary for any reason to adjust the fragments and retain them in position, and the conformation of the limb will be more regular, and the consolidation of the bone more perfect. 16. Apart from special indication, the limb submitted to extension should never be placed upon an ascending inclined plane, but upon a plane either horizontal or slightly declined.

The Infectiousness of Pneumonia.—Dr. R. Massalongo relates the history of a curious epidemic of pneumonia, occurring at Tregnago, a town of two thousand inhabitants in the province of Verona, Italy (*Lo Sperimentale*, August, 1885). The epidemic was not preceded by any special atmospheric changes to which its origin could be attributed, but began in a few houses situated near a pond which served as a place for washing clothes. In most of the houses there were from two to five cases, and the disease attacked the inhabitants of one house after the other in regular succession, never leaping over any. No special predisposition was shown as regards age, sex, or social condition. Of the inhabitants of the hamlet, one hundred were attacked with pneumonia during the epidemic, and thirty died. Numbers of micrococci, such as those described by Klebs, were found in the sputa, but no mention is made of the so-called pneumococci of Friedländer. The course of the epidemic would seem to point to the presence of a contagious influence, yet there are so many other possible explanations of the peculiar march of the disease, that it cannot be regarded as a very conclusive argument in support of the theory of infection.

Ophthalmia and Rheumatism of Joints.—Dr. Zatvornitski has published an account of two cases of rheumatic inflammation of joints following ophthalmia. The first was that of a young man who, while suffering from severe urethritis, conveyed the urethral secretion to his eyes. When the ophthalmia was at its height, the wrist became acutely inflamed. The eyes were cured by applications of nitrate of silver. The joint inflammation, after continuing in an acute form for ten days, gradually began to subside, so as to allow of the employment of active and passive movements. The second case was that of a newly-born infant, in whom ophthalmia appeared in one eye. Through carelessness and want of proper attention the affection extended to the other eye, and lasted for about six days. When the ophthalmia was most acute, it was noticed that the right elbow and wrist became swollen and inflamed, and shortly afterward the left ankle. The child's temperature was 104° F., and it was very much prostrated. The joint inflammation continued for some ten days, after which it gradually subsided. The remark is made in reference to these observations, that the first case may be merely an instance of gonorrhœal rheumatism. This would certainly seem the most obvious explanation. May not a similar suggestion account for the second case also?—*Lancet*, September 3, 1885.

The Cold Douche in Insomnia.—The following is recommended as a very efficacious means of producing sleep in insomnia associated with eruptive or continued fevers: The patient's shoulders are covered with a cloth and the ears plugged with cotton. Then the head being held face down over the edge of the bed, a fine stream of cold water is dropped upon the neck and occiput. The water should fall from a height of eighteen inches during a period of three or four minutes. The head is then dried, and the patient made comfortable in bed. As a general rule, sleep follows in a very short time.—*Concours Médical*.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, October 31, 1885.

THE PRESENT CONDITION OF NATIONAL HEALTH LEGISLATION.

THREATENED as we are with an invasion of small-pox from the north, and of cholera from the east, no occasion would seem to be more opportune than the present for calling the attention both of the medical profession and the public, sharply, to the anomalous condition of national health legislation. We do not need to discuss at this time the need of national sanitary legislation. Whatever diversity of opinion there may be as to the form of such legislation, it may be safely affirmed that, in view of our increasing commercial intercourse with foreign powers, and the facilities afforded for inter-State communication, the necessity for national legislation, through which the sanitary service of the several States may be efficiently co-ordinated is universally recognized. Passing over, then, the agitation of public health questions, which resulted in the establishment of the National Board of Health, which has rendered incalculable service to the country, let us come at once to the present condition of affairs.

Under the Act of Congress approved March 3, 1879, the National Board of Health was established. In accordance with that law the Board is required "to make investigations into, and collect information on, all matters affecting the public health, and to advise the several departments of the Government, the executives of the several States, and the Commissioners of the District of Columbia, on all questions submitted by them, or whenever in the opinion of the Board such advice may tend to the preservation and improvement of the public health." On June 2, 1879, Congress passed an Act enlarging the powers of the Board, and charging it with the duty of aiding State and local boards of health in their efforts to prevent the introduction of contagious or infectious diseases from abroad and their spread from one State to another. It was under the provisions of this Act that the Board co-operated with the health authorities of the Mississippi Valley in stamping out the epidemic of yellow fever of 1879, which made its appearance within a month after the passage of the Act; and again in 1881–82, with the authorities of the North and West, in putting an end to the progress of small-pox, which was rapidly overrunning the country from the Atlantic coast to the Mississippi Valley.

The record of those years is written, and the success which attended the efforts of the authorities, State and National, working hand in hand, established beyond a question both the necessity for national aid in such emergencies, and the wisdom of Congress in providing the legislation by which such co-operation could be secured. From that day to the present State boards of health, local boards, medical societies and associations, have been unanimous in their approval of the work of the National Board and urgent in their appeals to Congress and the President to support and strengthen it in its efforts to improve the health of the people.

The Act of June 2, 1879, took the place of an Act approved April 29, 1878, by which authority in sanitary matters was centered in the Surgeon-General of the Marine Hospital Service, and after defining the duties and powers of the Board, proceeds as follows:

"SEC. 9. So much of the Act entitled 'An Act to prevent the introduction of contagious or infectious diseases into the United States,' approved April 29, 1878, as requires consular officers or other representatives of the United States at foreign ports to report the sanitary condition of and the departure of vessels from such ports to the Supervising Surgeon-General of the Marine Hospital Service; and so much of said Act as requires the Surgeon-General of the Marine Hospital Service to frame rules and regulations, and to execute said Act, and to give notice to Federal and State officers of the approach of infected vessels, and furnish such officers with weekly abstracts of consular sanitary reports, and all other acts and parts of acts inconsistent with the provisions of this Act, are hereby repealed.

"SEC. 10. This Act shall not continue in force for a longer period than four years from the date of its approval."

In consequence of the provisions of this last section the duties of the National Board, so far as they were set forth in the Act of June 2, 1879, ceased on June 2, 1883, and since that date the Board has continued its operations under the Act of March 3, 1879.

In regard to the Act of June 2, 1879, the late Hon. Charles J. Folger, then Secretary of the Treasury, in his Report to Congress for the year 1883, used the following language:

"On June 2d last the Act of June 2, 1879, to prevent the introduction of contagious or infectious diseases, expired by limitation. There is now no legislation immediately to the same end. Whether there be need of reenacting any or all of the provisions of the Act of June 2, 1879, it is for Congress to determine." The decision of Judge Folger was in accordance with Section 12, Revised Statutes, edition of 1878, which reads as follows:

"*Whenever an act is repealed, which repealed a former act, such former act shall not thereby be revived, unless it shall be expressly so provided.*"

In the face of this provision of law, a circular has recently been issued from the Treasury Department, citing the law of April 29, 1878, and assuming it to be in force.

This circular emanates from the "Office of the Supervising Surgeon-General, U. S. Marine Hospital Service," is signed by that officer, and is approved by the Secretary of the Treasury and the President. A more flagrant instance of assumption of power and authority, under color of law, cannot well be conceived. Acting under

the provisions of this *repealed* law, the Surgeon-General proceeds "to frame rules and regulations, and to execute said law," and the Secretary and President approve his acts. Meantime the National Board of Health, the only national health authority now recognized in law, is entirely ignored by the department which it is required to advise on sanitary questions.

In view of the preceding facts it is apparent that national health legislation is sadly in need of revision, and we trust that, at the approaching session of Congress, such definite action will be taken as will determine positively the kind of central organization which we shall have, and the exact nature and scope of its duties. The danger of leaving the great and all-important question of the prevention of epidemics, such as cholera and yellow fever, to the discretion of the President, has been demonstrated by the ridiculous efforts which were made under his direction to control yellow fever in Texas, and the feeble measures now in operation to protect the country against small-pox. Fortunately, neither cholera nor yellow fever has reached us this year, and time is once more given to set our house in order. No proper effort should now be spared by the American Public Health Association, which is largely responsible for whatever national legislation we have, to secure its revision, and to remedy its manifest defects.

A PLEA FOR THE OLDER PHYSICIANS.

We print with pleasure the following note from an esteemed correspondent:

"Dear Mr. Editor: I have seen a great deal in medical journals about struggling young doctors, and the persecutions and hardships and injustice which they suffer. But can there not be a word said for the older men? Have we not also some hardships as well as some rights and privileges. I have been practising now, in a country town of fair size, for twenty-five years. When I began there were five physicians here, now there are twelve, several of whom belong to the class of the much-abused young doctors. I had to work hard for years to gain a standing and a lucrative practice here. I have got it, but I also have a family to support, and I still need all the money that I can honestly earn. But a new young doctor comes in here every now and then, and assumes at once that he 'knows it all,' and is just as much entitled to a living as I am. If I do not welcome him with all my heart, or try and thrust cases upon him, is it very strange?

"In my experience these poor, struggling young doctors are more eager to adopt new ways of gaining practice, more eager to advertise, and to worm their way into new families than we older ones ever were. Sometimes we are almost forced out of practice by these new bustling, business-like ways of the 'poor struggling youngsters.' There would not be much left for us, certainly, if we at once lent a hand to set them up in practice.

"Yours respectfully, ———."

Our correspondent has called attention to a veritable condition of affairs, and pleads his cause so well that we need add but little. We quite agree that a physician who has worked faithfully for a quarter of a century, acquires a certain amount of moral right to his ground, provided he has won his way by good work. Unfortunately, though much can be said, little can be done. Young doctors have studied medicine and received diplomas, with the impression that their education and their sheepskin entitle them at once to a living. They settle down for practice with this idea. When patients do not come to them, but go to the older man, they feel it as an injustice which justifies them in adopting energetic tactics.

A few remedial measures may be adopted now, however. For example, the older physicians need not be so ready to encourage any one who is likely to be their office-student, to study medicine. And again, more attention should be paid to ethical teaching in our medical colleges, and to informing young students of the proper mode of dealing with their fellow-practitioners.

ASPIRATION OF THE AORTA.

Mr. J. Dacre reports, in the Bristol *Medico-Chirurgical Journal*, "a case of sudden pulmonary congestion relieved by aspiration of the aorta," the aorta being aspirated by mistake instead of the right auricle. The patient was a man forty years of age, who had had some phthisical symptoms for a year. He was brought to the Bristol Infirmary suffering from a sudden and acute attack of pulmonary congestion and œdema. His symptoms were great lividity, cold extremities, a feeble, rapid pulse, and great dyspnœa. Loud gurgling râles were heard over the chest. His condition steadily grew worse until the patient became pulseless and apparently *in extremis*.

As there was apparently next to no systole of the heart, and no distention of superficial veins, it was determined to relieve the venous engorgement of the lungs and right side of the heart by tapping the right auricle itself.

Accordingly, a medium-sized needle and canula was inserted in the fourth intercostal space on the right side, close to the edge of the sternum, and passed straight through the intercostal tissue until it was felt to be in the chest; the point of the needle was then turned sharply inward under the sternum, and pushed in that direction for about an inch and a half, when it was felt to be in a cavity. On removing the needle, blood jetted from the canula and thirty ounces were withdrawn. For two hours the patient was more comfortable. He then began to sink again. Aspiration was repeated in four hours and sixteen ounces of blood drawn. This caused no relief, and the patient died about half an hour later. Post-mortem examination showed that the needle had passed immediately above the right auricular appendix and pierced the anterior surface of the aorta about a fourth of an inch above one of the semilunar valves. There were two ounces of blood in the pericardium.

We give considerable space to the foregoing because cardicentesis is a novel procedure, and one of which little is yet known. So far, the operation has not established itself in any wise as one which will help when all other resources are exhausted. It appears, in fact, probable that phlebotomy is better and as efficient. Still, on the other hand, experience so far shows that cardicentesis is not dangerous.

One practical point brought out, according to Mr. Dacre, is, that to reach the right auricle the needle should be inserted in the fourth intercostal space on the right side, near the sternum, and should be passed directly back.

THE ARSENIC HABIT.

We have, every now and then, to chronicle the existence of a new morbid habit. One of the newest and probably rarest, in this country at least, is the arsenic habit, a case of which is reported by Dr. T. D. Crothers, in the *Quarterly Journal of Inebriety* for October. The patient was an Englishman by birth, and a horse-jockey by occupation. He had led an irregular life and had probably drank considerably. He began to take arsenic about the year 1875, using it for the purpose of keeping off fevers. For five years he took from one to two drachms of Fowler's solution daily, and his general health continued good. From this time he gradually increased the dose until he was taking from twelve to twenty grains of arsenic daily (!), either in the form of the powdered acid or of Fowler's solution.

When seen in 1885, his appearance was that of good health, the face full, the skin clear and white, the eyes brilliant but unsteady, cutaneous sensibility was diminished, the appetite was poor, the action of the bowels irregular, and the heart was enlarged. There was no muscular weakness, but the gait was slow and hesitating. His sleep was broken, and he awoke mornings with a sense of exhaustion, which continued until he had taken his dose of arsenic. He complained of failure of memory, was very emotional, and showed evidences of eccentricity and mental weakness. There was a strong, offensive odor coming from the skin, apparently due to the elimination of arsenic.

Dr. Crothers' case is one of a unique character, and we regret that he did not use more care in substantiating his facts. It is generally admitted now that the practice of eating arsenic exists among the Styrians, and in certain parts of India, but even the most inveterate arsenic habitués of these regions do not take doses of more than two or five grains. The statement that a patient takes twenty grains daily certainly needs very strong corroboration.

Dr. Crothers states that, from correspondence with other physicians, he is led to believe that the secret use of arsenic is rapidly increasing. However this may be, it is pretty certain that the practice of taking twenty grains of arsenious acid daily will never become widely popular.

THE ETHICS OF CRANIOTOMY.

In cases of contracted pelvis, or in cases in which there is some other mechanical obstacle to the passage of the fœtus, four measures of relief are possible: the induction of premature labor, version and forceps, craniotomy, and Cæsarean section. There has been of late years considerable change in the feelings with which these various measures have been regarded. In the first place, a more careful study and examination of the patient has led to more frequent recognition of pelvic deformities, and hence the adoption of premature labor as a means of saving both mother and child. On the other hand, the increase of skill in obstetrical manipulation and in abdominal surgery has led to more frequent successes in the extraction of the unmutilated fœtus. Statistics show that craniotomy is a serious thing to the mother, perhaps almost as serious as Cæsarean section, when the latter operation is performed outside of hospitals. The country practitioner, if he understands the value of antisepsis in surgery, may often get better results by Cæsarean section than by attempting to drag the mutilated fœtus through a passage two and a half inches in the conjugate.

The tendency at present is, therefore, to limit the indications for the performance of craniotomy. This is certainly very gratifying, for the operation of craniotomy upon a living child is a thing from which every physician shrinks with feelings of profoundest dread.

The question has recently been raised, however, whether craniotomy upon the living child should ever be performed, or taught in the schools. The Roman Catholic Church has considered the matter, and one of its societies has pronounced against it. Some time ago the Archbishop of Lyons sent a letter of inquiry upon this subject to the Congregation of the Holy Office, at Rome, otherwise known as the Holy Roman Inquisition.

The following answer was received:

"Most Eminent and Reverend Lord: The most eminent, the Inquisitors General, in congregation assembled, on the 28th of the present month of May (1884), took under consideration the questions propounded by your eminence, to wit: 'Whether in Catholic schools of medicine the operation known as craniotomy may be taught, and under the following conditions, to wit: when this operation is omitted both mother and child may perish; but with the operation the mother's life may be saved, the infant alone perishing.' Having thought long and earnestly upon the subject, and having read those things which have been written thereon by learned Catholics (and which were forwarded to us by your eminence), we must answer that this thing cannot safely be taught (*tuto doceri non posset*); which response having been submitted to the Holy Father, and by him confirmed, I transmit to your eminence. Kissing your hands most humbly, I am your eminence's most humble and obedient servant.

"(Signed) Rev. Cardinal Monaco."

It would appear from the above that Catholic obstetricians are morally debarred from performing the operation of craniotomy upon the living child, even to save the mother's life.

This view is a logical and consistent one from the Catholic standpoint. It is not, however, that which physicians have always been taught, nor does it seem to us to be in harmony with the best and broadest ethical instincts.

THE REVIVAL OF THE USE OF MURIATE OF LIME.

Few substances, writes Dr. R. W. A. Crighton, in *The Practitioner*, really possessing marked therapeutic powers, have had more turns on the wheel of fortune, or, more correctly, of fashion, than the old muriate of lime —the modern chloride of calcium. First employed by the French physician Fourcroy, as also by several Dutch and German physicians during the last century, it does not appear to have been much used in Great Britain till

near its close, when strong testimony as to its efficacy in scrofulous affections was given by Dr. Beddoes; Dr. Wood, of Newcastle; Drs. Sanders and Hamilton, of Edinburgh; and Dr. Anthony Todd Thompson. Soon, however, disparaging statements as to its therapeutic powers were made by Professor John Thomson, of Edinburgh; Mr. Benjamin Phillips, and Mr. Samuel Cooper, of "Surgical Dictionary" celebrity.

These great names prevented many from giving the drug a fair trial, and it gradually fell into disuse, till, in 1848, Dr. Neligan, in his valuable work "On Medicines" almost refuses it any therapeutic recognition.

This neglect may also, in a great measure, be attributed to the introduction of the preparations of iodine by Coindet, of Geneva, in 1820, and to the powerful advocacy of cod-liver oil by John Hughes Bennett in 1841.

But during this time the remarkable powers of chloride of calcium were being patiently investigated by at least one individual, the elder Begbie, who bequeathed his large experience and rare therapeutic instincts to his son, the late Dr. Warburton Begbie. In 1872 the younger Begbie wrote an elaborate paper (*Edinburgh Medical Journal*, July) on its therapeutic action, in which he confirmed and extended its value in scrofulous and allied affections. Since that time the only contribution of similar value has been from the pen of Dr. Sinclair Coghill, of Ventnor, in the *Practitioner* for October, 1877.

Dr. Crighton himself now contributes the results of his experience with the drug. He has used it, he says, for years, and is confident that it has a distinct therapeutical value. Its use is indicated in scrofulous affections, and more particularly in glandular enlargements of the neck in children, where the glands are massed together, have an almost stony hardness, and do not yield to iodine and cod-liver oil. The lime salt is sometimes equally efficacious after suppuration has occurred. In scrofulous caries it has also produced remarkable results. In pthisis the remedy is not very efficacious.

Chloride of calcium is probably both a vascular tonic and a bone tonic. It is given in doses of gr. x. to xv. for adults, the crystallized salt being dissolved in syrup.

Medical Lectures to Ladies Only.—We have before commented upon an obvious and painful tendency to irregular and quackish practices on the part of medical women. It could only occur, we venture to say, to a lady homœopath to keep herself before the public by lecturing "to women only" on the sexual relations. The annual visitation of a scientific lady, who is in this particular line of business, occurs, we believe, at about this period. We have no desire to question the motives or doubt the eloquence and delicacy of the gifted medical lecturess. We are very decidedly of the opinion, however, that public lectures on the sexual relations do more harm than good, and that it is little less than an impertinence to have tickets and circulars bearing on the subject thrust into the hands of wives and daughters.

Distilled Water and Turpentine are said by Dr. Ralfe to be very efficient remedies for renal calculus.

News of the Week.

More Medical Colleges.—St. Paul and Minneapolis are each thriving cities, but evidently very unhealthy. We infer this from the fact that between them there are now three new medical colleges, with well-equipped faculties, consisting of a total of sixty-odd professors, while each college seems to be supplied with an enormous amount of clinical material. Minnesota is a great State, having nearly as many inhabitants as Philadelphia, and rather more than Brooklyn. There is no reason why it should not have a medical college, but is not three a little excessive for cities which five years ago, together, had only 80,000 inhabitants? In this connection we take the opportunity of chronicling, on the authority of the *Medical Annals*, the prospective organization of another new medical college at Wichita, Kan.

Dr. H. C. Fessenden, of Eastport, Me., a brother of William Pitt Fessenden, died October 22d, aged sixty-six years.

Bequest for the Erection of a Hospital.—The late Colonel Thomas M. Pierce, President of the Texas, Houston & San Antonio Railroad, made a bequest in his will of such a sum as his trustees may deem necessary, providing it does not exceed $20,000 to establish a charitable hospital on the line of the Sunset Route Railroad in Texas.

The Early Contagiousness of the Infective Exanthems.—M. Lancereaux, in a recent communication to the Académie des Sciences, stated that a series of facts, collected in his hospital wards, convinced him that small-pox, measles, and scarlet fever were transmissible from the onset. The period of incubation varied; it was from eight to ten days in inoculated small-pox; from ten to twelve in spontaneous small-pox. A mild form of small-pox might, by transmission, provoke a violent or a mild form.

Small-pox and the Gospel.—The Salvation Army at St. Catherine's, Ont., have spread small-pox more than they have the gospel, and it is proposed to burn their barracks.—*Sanitary News.*

Bequests for Hospitals.—We learn from the *Boston Medical and Surgical Journal* that the will of the late Mary G. Perkins contains bequests of $10,000 each to the New England Hospital for Women and Children and the Children's Hospital.

Another Resignation from the Congress.—Dr. George W. Major, of Montreal, has declined to serve on the Council of the Section of Laryngology.

St. Paul is to have a small-pox hospital. Minneapolis will, therefore, soon have two, if we understand aright the generous rivalry between these two great cities.

The Eleventh Congress of the Italian Medical Association, writes a correspondent of *The Lancet*, just held at Perugia, was in some respects more memorable than the most brilliant of its predecessors. Concurrently with its meeting the Royal Italian Society of Hygiene was to have been convened at Turin, but the promoters of these congresses, to obviate the inconvenience of two closely connected programmes being

carried out the same week in different parts of the peninsula, agreed to combine their forces and to have one assembly in common. The hygienists accordingly held their discussions in the Section of Public Sanitation, which the Medical Association always includes in its programme, the Umbrian capital being the rendezvous. The proceedings extended over so vast a field that we can only indicate a few of the subjects in which special interest was taken, subjects chiefly introduced by the representatives of the Florentine "Istituto di Studi Superiori." Professor Chiari read a very original paper on "Recent Advances in Operative Surgery," and Professor Tafani on "Some important Contributions of Microscopy to Medicine." Electricity, as became the fatherland of the science, especially in its bearings on therapeutics, came in for a large share of attention, chiefly at the hands of Dr. Turchini and Professor Dall'Eco, who exhibited electrical apparatus of a very ingenious and practical kind. The admirably appointed museum, which was a prominent adjunct to the Congress, was particularly rich in models of ambulance service and field hospitals; while invalid cookery had a department to itself, and the orthopædists and gynæcologists had their special wants supplied in several new and effective additions to their *armamentaria*. Nor must we omit mention of the startling specimens of animal petrification contributed by the veteran Dr. Comi, who, since 1834, has shown in a hundred different ways how human cadavera can be utilized for the manufacture of tables, desks, and such-like furniture, of exceptional solidity and elegance.

The First Circular of the Collective Investigation Committee of the International Medical Congress has been issued by the American members. It is neatly printed, bound in fashionable note-paper, and presents an attractive appearance. The names of the American members, N. S. Davis and A. Jacobi, are imprinted amicably side by side, and no one would believe that one had figuratively taken the other by the top of the head and incised his throat. The Committee begin their investigations with inquiries into the geographical distribution, prevalence, and etiology of rickets, acute rheumatism, chorea, cancer, and urinary calculus. Blank forms are sent which are to be filled out in a manner indicated by the context. As to the character of the questions and the selection of topics we shall have something to say later. Meanwhile we earnestly urge our readers to do all they can to further the work of the Committee. The papers are to be kept during the ensuing year, and the records handed in by January 1, 1887.

New Medical Faculties in Russia.—The Council of the Odessa University has commissioned the Physico-Mathematical Faculty to prepare plans for the establishment of a medical faculty. The rector has visited the St. Petersburg clinics, and has presented his report to the faculty. The university architect is to be sent to St. Petersburg and Kieff or Vienna in order to become acquainted with the arrangements of the university buildings in those cities. The original cost of the new medical faculty is estimated at £124,000, and the annual income necessary at £12,000. The present medical school in St. Petersburg, which is exclusively connected with the medical department of the army, is about to undergo several changes, so as to become somewhat similar to the medical faculties of the other universities.

A New and Jennerian Function for the Mosquito.—Dr. Carlos Finlay, of Havana, has published the results of several experiments he has made on the inoculability of yellow fever. He performed the operation, or rather got it performed for him by mosquitoes, which he caused first to sting a patient suffering from yellow fever, and shortly afterward a healthy person who was to be (with his own consent of course) the subject of the experiment. He found that the disease was only inoculable from the third to the sixth day. When two mosquitoes were employed, so that a double dose was given, the symptoms of the experimental disease were somewhat more severe than when only a single mosquito was used. Of eleven cases of inoculation, six were efficacious, one doubtful, and four negative. The period of incubation varied from five to fourteen days; the symptoms consisted of headache, pyrexia, injection, with sometimes an icteric tint of the conjunctiva, and in some cases albuminuria. The fever lasted, as in the ordinary form, from five to twenty-one days. The author believes that this method of producing artificial yellow fever will ultimately be found very valuable as a prophylactic against the natural and dangerous form of the disease.

The Reach of Quackery.—There is nothing, short, perhaps, of actual damnation, which some people will not believe quack medicines can prevent or cure. Just now in papers in Maine and other places exposed to the small-pox we find an advertisement alleging that "a sure preventive" of small-pox may be found in a certain quack doctor's pills.

A Montreal Physician on Vaccine.—My experience with vaccine has been large. I have used, I believe, samples of every kind that has yet been brought into Montreal, and some that I trust never will be sold here, and I think my successes and my failures have made it possible for me to say with positiveness that vaccinating in hot weather with vaccine brought from a distance is a delusion and a snare. I will never do it again, for I believe that it has done the cause (it is a "cause" in this city) a great deal of harm. It is difficult to persuade people of the utility of being vaccinated after the third or fourth failure, when they have been taught that two or three failures is sufficient to insure immunity from the disease. During the cold months I hope to vaccinate all but a small fraction of my patients that shall require it. We ought to have a properly conducted vaccine farm here, and I believe it would pay. During the next year or two (while King Variola holds sway) not less than 1,000,000 points will be required for Montreal and its surrounding country, and probably $75,000 will be paid for vaccine.—Dr. P. A. Laver, in *Can. Med. Record.*

Death of Professor Samuel G. Armor, M.D.—Professor Samuel G. Armor, Dean of the Faculty of the Long Island Hospital Medical College, died October 27th, at his home, in Brooklyn. He had been seriously ill only since Saturday. Dr. Armor joined the Faculty

of the Long Island College in 1866, as Professor of Therapeutics, Materia Medica, and General Pathology. The next year he succeeded Dr. Austin Flint, who had resigned, in the Professorship of Practice of Medicine and Clinical Medicine. From that time until the end of the last Spring term he attended steadily to college duties. He was a frequent contributor to medical literature, and built up a large practice in Brooklyn. Before moving to Brooklyn Dr. Armor had gained a reputation as an instructor in medicine, through connection with Western medical colleges for nearly twenty years. He was a practitioner at Rockford, Ill., for three years, beginning in 1844, and was then engaged for a course of lectures at the Rush Medical College of Chicago. In 1848 he became Professor of Natural Sciences at Cleveland University. In 1853 he became Professor of Physics and Pathology in the Ohio Medical College at Cincinnati. Three years afterward he was called to the Chair of Pathology and Clinical Medicine in the Missouri Medical College, his Alma Mater, at St. Louis. He remained there until 1861, when he went to Detroit as Professor of Institutes of Medicine and Materia Medica in the University of Michigan. It was from that post that he was invited to Brooklyn, in 1866.

The American Government and Quarantine.—Another illustration of the peculiar way in which our country has to deal with matters of quarantine is furnished by Texas. This State determined last summer to avoid the importation of yellow fever from Mexico, if possible. It, therefore, established a strict quarantine along its Mexican border. This quarantine was so disagreeable and vexatious to the Mexicans that that Government made a complaint to the National Government at Washington. As the result of this, Secretary Bayard sent a mild remonstrance to the Governor of Texas, which has been vigorously replied to. The Texan Governor concludes by saying that, "With all due respect to the Mexican Government I desire to say that Texas must be her own judge of the time and place for establishing quarantine for the protection of her people." The borders of our country are protected at some points by cities, at others by States, at others by the National Government, and at others not at all. "Here's a how-de-do," which our forefathers did not clearly foresee or wisely provide for.

Too Large Doses of Belladonna and Oxalate of Cerium.—In an item quoted from the *Therapeutic Gazette* (on page 460, Medical Record of October 24th) some errors occur in regard to the dosage of belladonna and oxalate of cerium. Every one who knows anything of either drug will see at once that fifteen grains of the extract of belladonna should never be given in one dose, even to an adult, much less a child. The usual dose of belladonna for an adult is from one fourth to one-half a grain. Again, oxalate of cerium is advised in doses of forty-five grains to a child one year old, and four drachms for a child seven years of age. The proper dose of oxalate of cerium is one to two grains.

The American Academy of Medicine.—The Ninth Annual Meeting of the American Academy of Medicine, was held during Wednesday and Thursday of this week, at the New York Academy of Medicine. Dr. Albert L. Gihon, Medical Director of the United States Navy, President of the Academy, called the meeting to order, and the opening prayer was offered by the Rev. Dr. Henry J. Van Dyke. Drs. S. M. Nelson, of Cambridge; J. H. W. Chestnut, of Philadelphia; Rufus W. Bishop, of Chicago; E. E. Mariot, of Springfield, Mass.; G. N. Acker, of Washington; H. V. Logan, of Scranton; H. W. Elmer, of Bridgeton; E. W. Cushing, of Boston; J. S. Wright, of Brooklyn; W. Osgood, of Yarmouth; C. A. Packard, of Bath, Me.; M. K. Oaks, of Auburn, Me.; A. Mitchell, of Brunswick, Me.; D. A. Robinson, of Bangor; C. A. Ring, of Portland; J. A. Spaulding, of Portland; G. W. Marshall, of Milford, Del.; W. A. Hugie, of Charleston; J. B. Shapley, M. H. Post, A. E. Briggs, and J. S. Alleymen, of St. Louis, and W. S. Davis, Jr., of Chicago, were elected Fellows of the Academy.

Dr. Robert Lowry Sibbet, of Carlisle, Pa., read a paper on "The Study of Medicine as a Means of Education;" Dr. Charles McIntire, Jr., of Easton, Pa., presented a paper on "Medical Supervision in Student Life;" Dr. Henry O. Marcy, of Boston, Mass., one on "Western North Carolina as a Health Resort;" and Dr. E. H. Sells, of this city, spoke of "The Importance of Climatology Considered as a Regular Branch of Study in Medical Colleges."

At the Wednesday evening session, Dr. Albert L. Gihon delivered a scholarly and eloquent address on "What is Medicine?" an abstract of which, together with the proceedings of the Academy in full, will appear in our next issue.

The following officers were elected for the ensuing year: Rhodes Stansbury Sutton, of Pennsylvania, President. Lewis P. Bush, of Delaware; S. J. Jones, of Illinois; R. Lowry Sibbet, Pennsylvania; Frederick H. Gerrish, Maine, Vice-Presidents. Richard J. Dunglison, Pennsylvania, Secretary and Treasurer. Charles McIntire, Jr., Pennsylvania, Assistant Secretary. The Committee recommended Pittsburg, Pa., as the next place of meeting.

Reviews and Notices.

Comparative Anatomy and Physiology. By F. Jeffrey Bell, M.A. Illustrated with 229 Engravings. Philadelphia: Lea Brothers & Co. 1885. Pp. 555. Manuals for Students of Medicine.

The conventional practice of teaching medical students *human* physiology instead of *physiology* is unquestionably a wrong one. It tends to narrow the student's view and make of him a memorizing mechanism, instead of giving him sound notions of what biological science really is. For this reason we welcome a work like the present, of which our text-book literature is much in need. For Professor Carpenter's work is now old and too bulky, while Bradley's is mainly a compend for cramming. Mr. Bell writes modestly in his preface as to the methods and character of his work. His method, however, which, is that of tracing the physiological history of the different organs or systems through successive animal forms is the correct one. He has, we think, erred in filling up his chapters with too many illustrative types, and consequently too many technical zoölogical names. We speak here in behalf of the medical student, who would, we feel sure, get a little dazed in going over the work. Mr. Bell has furnished a very large number of fine illustrations which contribute to the attractiveness of the book.

ACNE: ITS ETIOLOGY, PATHOLOGY, AND TREATMENT. A Practical Treatise Based on the Study of One Thousand Five Hundred Cases of Sebaceous Disease. By L. DUNCAN BULKLEY, A.M., M.D. Pp. 280. New York and London: G. P. Putnam's Sons. 1885.

DR. BULKLEY offers to the profession a book admirable in every particular. Its typography, its plates illustrative of microscopical studies, its tables, its arrangement and discussion of the subject under consideration, the complete bibliography, all give satisfaction to the reader, and make him feel that he has the book that he wishes on the subject, and not one which has been built upon the foundation of other works which he would rather consult for himself.

"Acne is one of those diseases which, while not causing physical suffering as a rule, can yet occasion an amount of real distress and annoyance which may often be much more unbearable than even a considerable amount of pain; and although it may never endanger life, it often can and does render existence so miserable that some individuals badly afflicted with it have even wished to die," writes the author; and many a physician can corroborate this statement. To relieve this condition, therefore, is worthy of high endeavors, and he who undertakes the task will feel grateful to Dr. Bulkley for having put the results of his vast observation and extended experience at his command.

PRACTICAL THERAPEUTICS: A COMPENDIUM OF SELECTED FORMULÆ AND PRACTICAL HINTS ON TREATMENT. By EDWARD J. BERMINGHAM, A.M., M.D. 4to, pp. 420. New York: J. R. Bermingham. 1885.

THIS volume is, as its name implies, a collection of prescriptions from all quarters for use in disease. It is interleaved and has well-arranged indices. It is handsomely printed and will doubtless suggest many devices to be followed where the usual plans fail.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Eightieth Annual Meeting, October 26, 1885.

DANIEL LEWIS, M.D., PRESIDENT, IN THE CHAIR.

OFFICERS FOR THE ENSUING YEAR.

President—Dr. Daniel Lewis.
Vice-President—Dr. Laurence Johnson.
Secretary—Dr. Wesley M Carpenter.
Assistant Secretary—Dr. Charles H. Avery.
Treasurer—Dr. Orlando B. Douglas.
Censors—Drs. F. R. S. Drake, H. T. Peirce, William O. Moore, F. M. Weld, and W. E. Bullard.

(Drs. W. T. Alexander and H. B. Conrad served as tellers.)

The Treasurer's Report showed a balance in the treasury of nearly four hundred and fifty dollars.

The Report of the Special Committee on Contagious Ophthalmia in Asylums and Residential Schools, was read by DR. R. H. DERBY, and contained evidence confirmatory of reports already made and published.

The Report of the Committee on Ethics stated that the six cases before the committee had been amicably settled.

The Report of the Committee on Prize Essays made known the fact that no essay had been offered during the past year.

The Report of the Board of Censors was read by DR. DRAKE, Secretary of the Board, and was accompanied by the report of Counsel William A. Purrington, Esq. These papers showed that the litigation for the suppression of quackery, in which the Society had engaged during the past year, had been reasonably successful. The proceedings instituted against the Eclectic Medical College of New York City had terminated by settlement, the College paying to the Society the sum of $1,500, and consenting to an abridgment of its powers, so that it can no longer confer *honorary* or *eundem* degrees; thus destroying a channel through which it might be possible to grant diplomas illegitimately.

AMENDMENTS TO THE BY-LAWS.

The following, proposed by DR. A. JACOBI, was unanimously adopted:

"That the *Comitia Minora* be directed to recommend no applicant for admission to membership unless he be a graduate from a Medical College in good standing, or a licentiate of a regular unsectarian State or County Medical Society of this or any other State; *or, if his diploma or license* be of a sectarian character, unless the applicant declare in writing his or her abnegation of sectarian principles and practice."

The following, recommended by the *Comitia Minora*, gave rise to a lengthy discussion, and finally were adopted:

"The annual dues shall be the sum voted at each annual meeting, but not exceeding five dollars.

"The annual dues shall be payable in advance after the annual meeting.

"They shall be remitted, for the year in which they join, to those who join the Society in the months of September and October.

"If any member shall fail to pay the yearly dues within thirty days after the fourth Monday in November, when the same shall become payable, it shall be the duty of the Treasurer to serve, in the manner in which notices in suits are required to be served on attorneys, upon each member so in default, a copy of this By-Law and a notice to the effect that, unless such dues are paid within fourteen days thereafter, his name and the amount due by him will be reported to the Society at its next succeeding stated meeting, and entered upon the minutes; and if they are not so paid, the Treasurer shall report the same accordingly. At the next stated meeting of the *Comitia Minora* after the date of such report, the *Comitia* may, by order, without further notice, strike from the roll the name of any member continuing in default, and he shall thereupon cease to be a member of the Society, provided that, upon his written application explaining such default, and the payment of all dues to the date thereof, or provided that the *Comitia* unanimously remits the arrears, the *Comitia* shall have power to remit the penalty of this By-Law."

The following, offered by DR. H. G. PIFFARD, was also discussed freely, and then referred to the *Comitia Minora* with power:

"It shall be the duty of the Secretary to prepare annually, and send to each member of the Society, a Register containing the names, addresses, and office hours of the active members of the Society—the Register to be prepared at such time, and in such manner, as the *Comitia Minora* shall direct."

The Society voted that the sum of *three* dollars shall be the dues from each member during the ensuing year.

The Annual Meeting then adjourned, to meet on the fourth Monday in November, at 8 P.M.

SALICYLATE OF METHYL.—Salicylate of methyl has been proposed as a therapeutic agent to supersede salicylate of soda. It colors salts of iron violet, is insoluble in water, of a light-yellow shade, and has an agreeable smell. It has been proved to have no effect on cold-blooded animals, except when it is applied in subcutaneous injections in large quantities, at the same time that the animal is breathing air charged with salicylate of methyl. The silver absorbed is partly distributed in the system, and partly discharged by respiration and the other forces of nature.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 14, 1885.

GEORGE F. SHRADY, M.D., PRESIDENT, *pro tem.*

MELANO-SARCOMA OF THE SKIN.

DR. JOHN A. WYETH presented a female patient from whom he had removed a tumor of the skin. She was seventy years of age. Fourteen years ago there appeared first, below the left eye, a small cutaneous growth which remained almost stationary for several years, and then enlarged gradually. Four years ago it was removed by some kind of caustic paste. She finally came to Dr. Fox's clinic at the College of Physicians and Surgeons, and by him was referred to Dr. Bronson, at the clinic in Thirty-fourth Street, where Dr. G. T. Jackson also saw the patient. Both confirmed the diagnosis of melano-sarcoma of the skin made by Dr. Fox, and Dr. Jackson referred her to Dr. Wyeth for an operation.

The surgical point of interest in the case was that it illustrated the remarkable vitality of the tissues of the neck and face when extensive portions of skin were raised for plastic purposes, and that this could be done with almost complete impunity. In this case the incision extended from the side of the nose to the outer canthus of the eye, was an inch and a half in length by one inch in width, and yet union by the earliest of all intentions was obtained. Fine carbolized silk was used for sutures.

Microscopical examination of the growth confirmed the diagnosis.

DR. H. J. BOLDT presented a specimen with the following history:

CYSTITIS SUPPURATIVA EXFOLIATA PUERPERALIS—CAST OF THE BLADDER.

Mrs. L. L——, aged eighteen years and eight months, primipara, confined September 18, 1885, of a healthy medium size, male child, in L. O. A. position. Pregnancy and labor were normal. On September 21st, the patient began to complain of colicky pains in the hypogastrium and pains in the lumbar region; both were tender on pressure, but nothing further unusual was noticed on examination. Micturition gave no pain and seemed to be at regular intervals for that period after delivery —four to five times in twenty-four hours; as to the quantity of urine voided during that time he was not positive. The bladder, however, was evacuated by catheter at that time, and about four ounces of urine were withdrawn, which had slightly acid reaction. Specific gravity 1.022, and contained albumen, blood, small quantity of pus, renal tube epithelium, bladder epithelium, and phosphates. Diagnosis: Nephritis catarrhalis acuta hemorrhagica. The temperature varied from 101° to 102.6° F.; these and all subsequent temperatures were taken in the axilla.

On September 26th, the patient began to complain of tenesmus and dysuria; only small quantities of urine could be passed at one time; the straining was severe and continuous. The catheter was again used, when eight ounces of thick, bloody, and muddy-looking urine were withdrawn, which had a putrid ammoniacal odor, alkaline reaction, sp. gr. 1.005, contained albumen, blood and pus in large quantities, shreds of connective tissue, renal tube epithelium, bladder epithelium—all three layers—the caudate-shaped epithelium of the deepest layer predominating. The bladder from this time on was regularly washed out with carbolated water 1 to 150 on account of the existing cystitis. The temperature was 99° F., and did not vary more than one degree either way until October 2d. On the morning of this date, information was given that the patient had spent a very restless night, had had more pain in the hypogastrium than previously, and that she thought something prevented her from micturating—it felt like a small lump near the urethral orifice. The temperature was 101.4° F. On inspection, a small sac-shaped mass, about the size of a bean, was seen protruding from the urethral orifice. A bimanual examination, which was rather unsatisfactory on account of extreme tenderness over the bladder and intra vaginam, revealed an œdematous, very painful swelling on the anterior vaginal wall, just above the symphysis pubis. The position of the uterus, on account of existing tenderness, could not be made out. Turning again to the small mass, which he took to be either a part of the urethra inverted, or the inverted bladder, it was found that it could be easily reduced, and then the viscus was washed as previously. Several hours later he found the sac protruding again, and then about the size of a small walnut, emitting an extremely fetid odor. Feeling almost certain that he was dealing with an inverted sloughing bladder, he became greatly alarmed as to prognosis; it was necessary to reduce the sac, however, before washing the bladder could be accomplished. The temperature was now 103.2° F., but went down to 101.6° F. about an hour after the viscus was cleansed. Early in the afternoon the sac-like mass protruded again, much pain, tenesmus, etc., being present; temperature 103.8° F. The bladder was washed out with short intervals almost continuously, until the temperature was reduced to 101.8° F. Dr. Boldt suggested a consultation, and Drs. W. T. Lusk and W. H. Van Wyck were sent for by the family. Both gentlemen agreed with his views of the case, and the treatment was continued with the addition of dusting iodoform upon the protruding mass.

On vaginal examination, Dr. Lusk thought that the swelling felt by Dr. Boldt, and apparently fluctuating, might be an abscess between the walls of the bladder, but the use of an aspirator did not show this to be the case. The following morning, soon after the bladder was washed, the specimen, which he would call "a cast of the bladder," was discharged, the thick portion of the sac which first protruded being first discharged. Immediate relief was experienced by the patient. The washings at first always contained blood, pus, shreds of connective tissue and muscular structure. The temperature previous to each washing being 101.2° to 101.8° F., always fell from 1° to 1.2°. Incontinence of urine was persistent to the end. To get an idea concerning the quantity of urine voided in twenty-four hours, a bed-pan was placed under the patient, and it was found that one hundred and twenty-eight ounces were passed; specific gravity, 1.002; the same microscopical appearances as previously, only more *muscular* structure could be seen by the naked eye, and verified by the microscope. Throughout the course of the case the urine always contained large quantities of phosphates.

From October 5th something seemed to obstruct the introduction of the catheter at a point, by measurement, 2¼ inches from the orifice of the urethra; the instrument could be introduced without causing pain 2¼ inches, and beyond that it gave considerable pain. The patient felt again as though a lump was lying in the urethra and caused much annoyance.

October 9th, 9 A.M.—Patient had spent a restless night, nothing otherwise unusual was noticed; temperature, 101.4° F. At 5 P.M. she was very restless; pulse, 140; temperature, 103.4° F. This apparently sudden change caused him much alarm, and Dr. Lusk was requested to see the patient again. At 8 P.M. the temperature was 104.8° F.; pulse, 150 and feeble. Dr. Boldt thought that probably some loose exfoliated muscular tissue might be in the bladder, giving rise to the obstruction to the introduction of the catheter, and causing the high fever. An examination per urethra disproved this. The remainder of the walls of the bladder were very much thickened, infiltrated, and œdematous, and the cavity much diminished in size. I do not think it could contain more than an ounce or an ounce and a half of fluid. With the exploring finger all sides of the bladder were readily felt, and all parts of the bladder seemed denuded of their mucosa, except just around the internal urethral orifice. A few rough spots on the sides and at the fundus

were also felt; probably from these the muscular tissue came, shreds of which were continuously found in the urine, upon the napkins, and in the washing. Stimulants and antipyretics were used per rectum, as nothing would remain on the stomach. About an hour later the patient began to develop cerebral symptoms.

At 1.30 A.M., October 10th, in spite of energetic treatment, the temperature was 106.4° F.; pulse imperceptible, and cerebral symptoms very marked.

Death took place at 1.10 P.M., October 10th. How high the temperature went just previous to death he did not know. Unfortunately an autopsy could not be obtained.

Dr. Boldt thought it probable that the necrotic process began at the fundus of the bladder. So far as he had been able to ascertain, cases of this kind had not been reported in this country, and but few in Europe. In none of the cases in which the destructive process had advanced as far as in this had the patients recovered.

The cerebral symptoms in this instance were probably due to septicæmia.

The disease had been met with in either the pregnant or puerperal state, and with the exception of one reported by Aveling, of London, and this one, the primary trouble had been, in all the cases reported, retention of urine, due to either displacement of the gravid uterus or neglect in the use of the catheter after delivery. The remarkable diminution in the size of the cavity of the bladder was also an interesting feature of the case.

DR. E. M. CUSHIER presented a specimen of

SARCOMA OF THE OVARY,

removed, post-mortem, from the body of a woman forty-nine years of age, who died in the New York Infirmary for Women. The tumor had been noticed only about one year, and its growth was very rapid. The entire upper part of the vagina seemed to be spread out, drawing up the cervix, and apparently diminishing its length considerably. The immense abdominal mass gave an indistinct fluctuation. The suffering of the patient was so great as to lead to the consideration of the propriety of an operation, and Dr. James B. Hunter saw the case in consultation, who thought it altogether probable that the growth was malignant, but at the same time believed it to be justifiable to give the patient the benefit of the doubt. The patient was exceedingly desirous to have the operation performed, and an exploratory incision was made October 24, 1885. It was very soon ascertained that, on account of extensive and firm adhesions, it would be impossible to remove the tumor, which presented the appearance of a malignant growth. The abdominal wound was therefore closed, and the patient rallied well from the ether; but as soon as she discovered that the tumor had not been removed, she lapsed into a state of despondency from which she did not arouse, and died on the fifth day after the operation.

From the time of the operation until death there was scarcely any elevation of temperature or acceleration of pulse. At the autopsy the tumor was found so adherent that it was impossible to remove it without dissecting away a portion of the muscular tissue of the abdominal wall. The cervix uteri was normal as far as the internal os, but beyond that the entire organ was thickly infiltrated with masses resembling the tumor itself. No left ovary was detected, it being obliterated by the growth. The right ovary was perfectly normal, as well as the corresponding Fallopian tube. There was some enlargement of the retro-peritoneal glands. The liver and spleen were normal. The lower lobe of one lung was in the stage of red hepatization; the other lung contained some nodules which presented the same appearance as did the tumor. There were no rational signs of pulmonary disease.

Microscopical examination showed that the tumor consisted entirely of spindle-shaped and round cells, making it a sarcomatous growth. The nodules in the uterus showed the same spindle-cell and round-cell growth undergoing mucoid degeneration in places, and the nodules in the lung showed round-cell infiltration.

The most interesting question was whether the tumor was originally a sarcoma of the ovary, or a fibroid of the uterus which underwent degeneration. Muscular fibres, such as belong to the uterus, were entirely absent from sections of the tumor; at the same time there was absence of anything suggestive of original ovarian tissue. Dr. Cushier, however, was not at all sure as to its being a real ovarian tumor.

Dr. Cushier also presented a

DERMOID CYST OF THE OVARY

which she removed October 8, 1885. It was interesting from the fact that the patient was confined about three months previous to the operation, and was not aware that she had a tumor until shortly previous to the last pregnancy, when she noticed a swelling about as large as a walnut just above the pubis. After confinement she observed that she did not get smaller, and had several attacks of pain which were referred to peritonitis.

The patient was seen at the infirmary first about the the middle of September, when she was examined by Dr. Daniel, who diagnosticated the enlargement to be due to some form of abdominal tumor. After admission the temperature rose to 101° F., accompanied by pain which required the use of anodynes. Within a week or ten days this attack subsided, pulse and temperature became normal, the general condition of the patient improved, and the diagnosis of cystic tumor of the ovary was made. At the operation, adhesions were found throughout the entire extent of the tumor, but these were broken up with some difficulty, not extreme, however, and the patient was doing very well. After removal it was found that the cyst contained a large mass of hair, a tooth, and a spicule of bone.

DR. T. MITCHELL PRUDDEN thought that in the first case the chances were very much in favor of the tumor having an ovarian origin, from the fact that sarcoma of the ovary is so much more likely to occur than sarcomatous change in a fibro-myoma. Furthermore, the fact that there were no other fibro-myomata favored the view that the growth originated in the ovary, because fibro-myomatous growths were usually multiple.

CONGENITAL CYANOSIS.

DR. L. E. HOLT presented the kidneys, heart, and lungs removed from a case of congenital cyanosis, the child dying forty-eight hours after birth. The history of the family was distinctly syphilitic, and the duration of pregnancy was eight and a half months. The child was a female and weighed from four to four and a half pounds. Respiration on the second day was markedly accelerated, 180, and the pulse was so rapid that it could not be counted. Examination of the heart was made, but nothing could be determined on account of the rapidity of its action. Examination of the lungs revealed over both sides a marked diminution of pulmonary resonance, and the presence of many fine râles. The child was found dead in bed.

The lung was solid, did not crepitate at all, and sank readily in water.

The foramen ovale was large enough to admit two fingers; the ventricles were slightly thickened.

The spleen was enlarged, firm, and showed congestion.

The kidney was slightly softened externally, but it was evident that there was some interstitial increase. The cortex was pale; the pyramids distinct, and contained uric acid infarctions.

With reference to the cyanosis, it was explained by the condition of the lungs, as it did not necessarily follow when the *foramen ovale* was patent, if there was no pulmonary obstruction.

Another interesting question pertained to the kidneys,

as it had been said by Orth that uric acid infarctions was positive evidence that the child had breathed.

The third interesting question was, what influence did the syphilitic history exert in the case?

The Society then went into executive session.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN PRACTICAL MEDICINE.

Stated Meeting, October 20, 1885.

ALFRED L. LOOMIS, M.D., LL.D., CHAIRMAN.

THE CHOICE OF REMEDIES.

DR. LAURENCE JOHNSON read a paper on the above subject. (See p. 478.)

The discussion was opened by DR. W. H. THOMSON, who believed that the author had done good service in calling attention to the necessity of altering our pharmacopœia in the near future in order to keep therapeutics from parting company altogether with physiology and pathology. How was this to be done? His own suggestion would be to see in the first place to what extent the terms now used corresponded to accepted physiology and pathology. For example, to begin with the word tonic, what does it correspond to among the physiological functions of the body? The word originally was taken from music, and accorded with the manner with which a string was put upon the stretch to give it tone. But we are told in applying it that iron is a tonic, vegetables are tonics, a sea-bath is a tonic, and also a sea-voyage is a tonic, and therefore the word really means anything which does good. When, however, we take up the action of remedies we find under this head that a cold shower-bath, which acts only by an external impression, is classed with cod-liver oil, which acts as a food. Of course there can be positively no two operations in these agents which they have in common except that they benefit the patient. So the word tonic comes to mean something which benefits the patient, and the question arises, How can we retain the word very much longer? With the exception perhaps of digitalis and one or two others, there are no cumulative effects in the vegetable remedies. Stramonium relieves an attack of asthma and does this as effectually for ten years as when first taken; but the patient is no nearer to a cure of his disease than when he began its use. With the administration of iron, however, the patient at the end of the twentieth dose is nearer a cure of his disease than after taking the first dose. Hence, he would like to see banished from the Pharmacopœia the word tonic, and with it nearly the whole list of tonics with which the work is now burdened.

So also with the word alterative, and the whole class of alteratives, some of which are contradictory in their action. In the name, and often in the agents themselves, there exist the final remains of old physiological opinions and extinct systems of pathology. He would say that our present Pharmacopœia was in very sad need of an elimination, and in making this we should be guided exclusively by the acknowledged physiology and pathology of the day, so as to bring the two into some kind of harmony.

The author of the paper had very properly suggested one desirable purpose to guide us, namely, that in the daily use of vegetable remedies we should have a suspicion of any which did not contain an active principle that could be isolated. At the same time, there were some remedies which Dr. Thomson would prefer to have remain as they are; for example, ergot, rhubarb, and some others which were most effective when administered in substance.

With reference to the effects produced by remedies, it was very unsatisfactory to go to clinical experience because it was such an uncertain course and entirely dependent upon the observer. Clinical experience when cited in favor of any therapeutical measure as well as therapeutical agent contained so many sources of error that he feared we should be far from being able to reform our Pharmacopœia upon such evidence.

Lastly, he would suggest, as an element of reform in our Pharmacopœia, the selection of some extensive principle which would in its application govern and determine the classification of remedies. For example, he would divide all remedies into those which produce cumulative effects and those which never act in this manner. If we could succeed in doing that we could quickly simplify our Pharmacopœia. Medicines which act cumulatively are those which must be given in repeated doses, as, for example, mercury given until the system is affected; on the other hand, there are remedies which produce their effects in a single dose, and never otherwise.

In conclusion, Dr. Thomson thought that we should set about the work of selection of remedies and of adopting a plan by means of which three-fourths of the Pharmacopœia of the United States might be eliminated.

DR. F. A. CASTLE said there were two points in the discussion of the subject to which attention should be directed: First, the remedies to be used in the treatment of any particular case, and second, the remedies which should enter into the Pharmacopœia. It was the habit of an old Scotch physician to select a few remedies belonging to the different classes, and rarely did he use anything else, unless it was something quite new and the value of which was thoroughly established; at the same time, he never left a stone unturned to find out something new with regard to the old remedies. This principle kept in view at the bedside might be of great service in prescribing in the cases which we were called upon to treat.

But, on the other hand, when we undertake to make a pharmacopœia which shall contain a description of the remedies which are recognized by the profession of a country, such as the United States, or Great Britain, or Germany, it was like undertaking to sweep back the Atlantic Ocean with a broom to say what should be left out and what should be retained. The Pharmacopœia does not attempt to tell what shall be used or what shall not be used, but simply attempts to describe remedies which have been used sufficiently to warrant their introduction. There was no doubt that in the formation of every pharmacopœia many remedies were introduced largely as a matter of prejudice, and not as a result of intelligence; but to undertake to wipe out three-fourths of the Pharmacopœia of the United States was a thing which could not be done. Dr. Castle would impress this fact, that while each one may make his pharmacopœia to satisfy himself with regard to the activity of remedies, he needs to be more liberal with regard to the remedies which he intends to offer to the medical profession of his country.

With reference to the choice in a number of articles belonging to the same class, this might be looked at from another standpoint. There was no doubt but what there were many remedial agents in the vegetable kingdom which possessed similar powers, but suppose it were agreed to ignore all but one, which by general consent was regarded as the best, the result would be that the cost of the article chosen would be very considerably enchanced because of the increased demand. It seemed to be a very wise provision of nature that the same principle was found in a number of remedies belonging to the vegetable kingdom.

IS TYPHOID FEVER EVER OF SPONTANEOUS ORIGIN?

DR. J. H. EMERSON opened the discussion and said:

It is my conception of the office of one appointed to open a discussion that he should present an introduction to the subject proposed; that the presentation of his own views is permissible, but should not be a prominent feature; that his endeavor should be to map out the

field, and that he should reckon it a success if the discussion ultimately follows the lines he lays down.

The subject of the evening is the following: "Is typhoid fever ever of spontaneous origin?" It is not a new topic, but has engaged the attention of the profession in many lands, and at the meetings of many learned societies for thirty-five or forty years, and has been the incentive to much painstaking and thorough research in following up the history of isolated outbreaks, and to ingenious and learned arguments. Leading authors have coined names for the disease, such as pythogenic and enteric fever, and ileo-typhus, which were expressive of their views of its etiology, and much time has been spent in rather unprofitable discussions turning on the significance attached to a word, such as *contagion*. One point after another has been gradually established, and the assent of both parties to the controversy won, and the investigations on micro-organisms published, within the last five years especially, have done much to simplify the question at issue; for if it can be proved that there is a bacillus which bears to typhoid fever the relation which the spirillum, for example, bears to relapsing fever, the position of the disease as to its etiology is fixed. If this proof is wanting, and it must be said that the profession at large is not yet satisfied of the existence of such a microbe holding such relations to typhoid fever, then the argument must follow other channels. Now Gaffky, as quoted by Green, says that observers believe that a certain bacillus is the cause of typhoid, that it is constantly present in typhoid, is recognizable from all known bacilli, and is not found in any other disease. The identity or non-identity of typhus and typhoid fevers was still a mooted question when I began to study medicine, a point I refer to simply to illustrate how gradually the problems presented by this disease are being solved. It is now no matter of dispute that typhoid fever is conveyed or communicated through the agency of the dejecta, notably when these have undergone certain changes to which they are liable on exposure, especially in drains or vaults, it may be a long time after emission. But is that the only way in which it is transmitted? The study bestowed upon various localized outbreaks of this disease has brought to light a series of most interesting and instructive facts as to the media of its dissemination, and the agencies by which a single case may infect a whole community. Most unexpected sources of contamination of water have been laboriously traced out, involving indirectly the milk-supply, and it is very evident that study must be directed in these and other new directions; *e.g.*, to the persistency of life in typhoid germs, also to the diseases of animals, in view, especially of the outbreak at Kloten, although good authorities still express doubts whether any animal suffers from the typhoid fever of man. So it seems that as knowledge has increased, and as methods and instruments of research have improved in efficiency many questions formerly in dispute have been cleared up; "obscurity" in causes has given place to clearness, and ways of communication previously unsuspected have been made known. Thus a point has been reached where the question now is, whether one's powers of belief would be most taxed in supposing that the seeds of the disease, originating in ways which all recognize, have been conveyed to the new victim through agencies which have hitherto eluded detection, but which subsequent investigations may yet disclose, or in imagining that the germs of the disease, which even those who maintain the theory of its spontaneous origin now concede to be a material substance, a *contagium vivum*, can originate from sources independent of previous cases of typhoid, and in substances never yet proved to have a causative relation to it.

I suppose it would be correct to make three groups, in one or other of which upholders of all the chief opinions on this question would find a place: 1. Those who believe with Murchison in the spontaneous origin of typhoid fever. 2. Those who believe with Liebermeister, as quoted by Homolle, that it never originates spontaneously, and that the condition necessary for its development is the presence of a germ derived from a typhoid patient. 3. Those who incline to the latter view, but who prefer to hold their judgment suspended in the absence of positive demonstrative proof, which has not yet been furnished.

Dr. S. Oakley Vander Poel referred to the general proposition of the transmissibility of typhoid fever by ingestion and respiration, and quoted some of the views formerly entertained concerning the disease. For example, Murchison claimed that typhoid fever might originate whenever the human excreta were allowed to undergo a certain amount of fermentation. To that view Dr. Vander Poel could not now fully subscribe, although for many years he entertained the view that the disease could originate *de novo*. The argument in favor of a specific cause of typhoid fever was of two kinds, the negative and the positive. First, with reference to the negative argument, if it could be shown that in many instances polluted water and food had been used without developing typhoid fever it was an argument in favor of a specific cause for typhoid fever. If, on the other hand, it could be proven that the direct introduction of excreta from typhoid-fever patients into the food and water partaken of was followed by the development of typhoid fever in persons or in communities, it furnished a positive argument in favor of a specific cause of typhoid fever.

It was a fact established beyond question, that in this country many cities were supplied with polluted water, and yet typhoid fever was no more prevalent in those cities than in others in which the water-supply was of the purest kind. For example, the city of Albany received its water-supply largely from the Hudson River, into which the sewage of Troy, situated five or six miles above, was emptied, and yet Albany had not suffered from typhoid fever more than other cities. In the southern portion of Albany there still remained several wells from which the inhabitants took water for drinking and cooking purposes. It was found on analysis that this water was intensely polluted, and the Board of Health ordered that the wells be closed. But the citizens objected and continued to use the water, and not a case of typhoid fever occurred in that part of the city. Such evidence was negative in character.

On the other hand, the late epidemic which occurred in Plymouth, Pa., furnished a very powerful positive argument in favor of a specific cause of typhoid fever in the fact that while the city was supplied with the polluted water from the Susquehanna, typhoid fever did not occur, but as soon as the water in the reservoir became polluted by the mountain stream, which received the dejecta of typhoid-fever patients, typhoid fever broke out within the ordinary incubative period.

Similar instances had occurred in England. Dr. Vander Poel believed that large towns were not the proper places in which to make investigations of this kind, and that the best evidence could be derived from the study of cases occurring in small communities, where each one could be traced to its cause.

Dr. W. H. Thomson said that he would as soon expect typhoid fever to be developed spontaneously as potatoes.

The Chairman was not in the position which Dr. Thomson was, because he did not think the question was by any means yet settled. In discussing this subject the first question which came to him was, Did typhoid fever possess any diagnostic facts, clinically or pathologically? The history of typhoid fever, especially as written by the Germans, would lead one to believe that there were three diagnostic symptoms; a peculiar range of temperature during the first week, a rose-colored eruption, and a characteristic diarrhœa; and that after death there is a characteristic ulceration of the intestines.

So far, however, as the typhoid fever of New York was

concerned, if it occurred, these symptoms were not necessarily present, neither the characteristic range of temperature, the characteristic spots, nor the characteristic diarrhœa, in a large proportion of cases. Yet what was called typhoid fever occurred abundantly.

Again, intestines were seen in which there were ulcerations, and yet during life there were no symptoms indicating the presence of typhoid fever, but at the same time these ulcerations could not be distinguished from the ulcerations belonging to typhoid fever. There was a septic fever produced by drinking polluted water, in which the intestinal lesions could not, by the naked eye, be distinguished from those said to be characteristic of typhoid fever. Therefore, he would say that there was nothing necessarily specific about typhoid fever. But the next question which arose was, Is it a contagious disease? If there was any specific poison which produced typhoid fever, it was a contagious disease. But clinical experience did not illustrate that typhoid fever sustained this theory; for, in the hospitals to-day typhoid-fever patients were found side by side with other patients, and it was not expected that by so placing them the poison would be conveyed from them to other patients. It was not contagious and it was not necessarily specific in its cause.

It had been established that certain conditions were necessary to the development of the poison of intermittent fever, and the question might arise, could not typhoid fever be developed in the same manner? but typhoid fever did not so behave.

Dr. Loomis would not commit himself to the spontaneous origin of typhoid fever, and yet he was not willing to commit himself to the existence of a specific germ as the cause of typhoid fever. There was undoubtedly a specific poison in all fevers; that is, a poison which produces malarial fevers, but which differed from the poison that produces a contagious fever. A contagious poison was never of spontaneous origin; there must be a case to get a case from, and typhoid fever was not contagious.

The more he saw of typhoid fever as it occurred in New York, the more he inclined to the name of continued fever, given by the elder Professor Wood, as the name best applied to all those fevers which were partly malarial and partly typhoid, or as they had been called typho-malarial; all apparently of one type but varying very greatly in their manifestations in different cases.

Dr. R. A. Caldwell asked, what was understood by a fever developing spontaneously?

The Chairman replied, a fever which developed without known specific cause.

Dr. Vander Poel desired to take some exceptions to the Chairman's remarks, who stated that because typhoid fever was not contagious, it was not necessarily due to a specific poison. He made a distinction between transmissible disease and contagious disease. Yellow fever was not contagious, and yet it was a specific disease and easily transmitted. Cholera also was not a contagious disease, but it was easily transmissible like yellow fever, and in either case it was only after the fermentative process had begun that the poisonous element was developed and became contagious. In typhoid fever the dejections are contagious, not in the sense of conveying the disease from one person to another, but through the medium of the dejecta, which have undergone certain fermentative changes, the disease becomes more or less contagious in its character. Yellow fever, cholera, typhoid fever, neither of which were strictly contagious, were transmissible from person to person.

The Chairman said that perhaps he did not make himself exactly clear in his former statement. He recognized contagious and infectious diseases. The contagious diseases were infectious, but the infectious diseases were not necessarily contagious. Typhoid fever was an infectious disease, but the poison of typhoid fever could not be carried directly from the human being in which it was produced to another human being and cause the disease; it must first go through certain changes before it became infectious.

Dr. W. H. Thomson said that it was sometimes profitable to discuss the meaning of medical terms. He had been accustomed, in his lectures on disinfection, to use two terms with three subdivisions; first, he spoke of communicable diseases; meaning thereby those which pass from a human or animal body to another human or animal body. He preferred the word communicable, because it did not define the mode in which the disease passed from one body to another; restricting the term to the fact that every case must have originated from an antecedent case of the disease and not from any other source.

The second class were the malarial diseases, an unfortunate word, because it implied transmission through air; but these diseases, instead of having their origin in the human or animal body, came from a thing or place.

To which class does typhoid fever belong? To the communicable from an antecedent case, or to those which come from a place or thing?

He believed that when the subject was studied in this way, we should admit that typhoid fever was a communicable and not a contagious disease. He was very far from believing that it had yet been demonstrated that typhoid fever was due to a micro-organism, and yet the laws of typhoid fever, as it appeared in this country, showed that it belonged in general character and results to the communicable diseases.

Dr. A. A. Smith said it seemed to him that the solution of the question lay in the answer to the other question, Has a typhoid bacillus been discovered? If it had, then the question almost answered itself. If he interpreted correctly the remarks which had been made that would be the position taken by all who had spoken, and until it was decided whether or not there was a specific bacillus which belonged to typhoid fever and to no other disease, the question of spontaneous origin could not be answered. The very latest reports from German sources were from Gaffky, who took the position that he had discovered the typhoid bacillus. He had made observations in sixty-five cases of typhoid fever, in which in nearly eighty-five per cent. he was able to demonstrate the presence of the bacillus in the liver, spleen, blood, and mesenteric glands. It seemed to Dr. Smith that we must still remain on the fence, as the Chairman had expressed himself as being willing to do, until this fact was proved. If it had been proved that a specific bacillus existed in other diseases, it seemed to him that we should not commit ourselves to a positive opinion until it was demonstrated whether or not typhoid fever had a specific bacillus, and he was unable to see how the question of spontaneity of origin could be decided until that question was settled. He confessed that he had seen cases where he had been at a very great loss to determine where the poison which produced unmistakable typhoid fever came from. He belonged to the third class referred to by Dr. Emerson. He would like to be convinced that there was a typhoid bacillus, and should hold his opinion open until microscopists had learned more with reference to micro-organisms.

Dr. A. Jacobi said that was exactly the point where he rested his doubt, as microscopists might discover very many bacilli, but that would not prove that the bacillus was the cause of the disease. It had already been learned from microscopists that there were bacilli in a number of different diseases, and it was quite natural to reason from that that we were in a position to assume that the etiology of all diseases in which bacilli could be found could be explained. Obermeyer found a bacillus in relapsing fever at a certain period in the disease, but it had not been proven that it was the cause of the disease. It had not been found in the beginning of the disease, but even if it had been found at that period it would be doubtful whether it was the cause, or whether the disease was due to causes which were aroused by the bacillus, or whether

the bacillus was the result of the disease. He did not believe that we were justified in saying that the bacillus of relapsing fever was the cause of the disease.

With regard to other diseases, microscopists had been anxious to find bacilli, and thus Gaffky had his bacillus, and Klebs had his bacillus, and so on. So with reference to diphtheria, Klebs had his bacillus, which he assured us was the cause of diphtheria; Eberth discovered his bacillus, which he also said was the cause of diphtheria; and even so cool-headed and sound a man as Gerhardt was led to make the statement, only a few years ago, that undoubtedly diphtheria was a bacillus disease; but as Klebs had discovered one bacillus, and Eberth had found his bacillus, he declared that it was probable that *two different* bacilli could be the cause of diphtheria.

With regard to the question raised by the Chairman as to the existence of typhoid fever, we have heretofore been accustomed to hear him express his opinion quite positively; but to-night the Chairman seemed to be inclined to feel that he was rather on the fence, and several of the gentlemen had said the same thing, and Dr. Jacobi was also willing to place himself among them. But while upon the fence they would probably have their eyes open, and not lose sight of criticism. Those who were guided by the skill of experts who lived under the shadows of Boards of Health, even of such as that over which Koch himself presided, were very apt to be prejudiced in favor of certain theories. Gaffky was committed to the finding of a bacillus, and it was kind of him to find one in only eighty-five per cent. of his cases; if he had been in Gaffky's place he would have found the bacillus in one hundred per cent. Dr. Jacobi had always been glad that bacilli were found, as he was always glad to receive pathological facts recently discovered.

With regard to the position of the Chairman, he would say that it was not necessary to reject typhoid fever as a morbid entity. If it was found that it presented a variety of phases, that was no more than had been seen in other diseases. Even as pronounced a disease as scarlet fever manifested itself in various ways, and so also did measles, sometimes so varied that these diseases were frequently difficult to recognize. Furthermore, in certain years, measles and scarlet fever did not exhibit any pronounced mortality, while in other years the percentage of mortality was immense; still, both set of cases were certainly measles and scarlet fever. Thus it was with typhoid fever. Dr. Jacobi was aware that we had never seen a single epidemic in this country in which typhoid fever had prevailed as the Germans had described it, and even the Germans were beginning to modify their opinions, yet it was only within the last few years that they admitted that typhoid fever might occur without diarrhœa, but that in those cases the characteristic changes in the intestines existed. He would say that here we have a large majority of cases of typhoid fever in which there was no diarrhœa, and that even perforation of the intestines might occur without diarrhœa. The one anatomical fact which he would regard as characteristic of typhoid fever was the ulceration of Peyer's patches. The Chairman appeared to believe that the same ulcerations were found in septic enteritis, but what Dr. Jacobi had seen presented a little different appearance. The ulcerations in septic enteritis were not only about Peyer's patches, but were all through the intestines, beginning in the *upper portion* of the small intestines and extending throughout their entire length. That was what we never saw in severe cases of typhoid fever, in which the ulcerations were confined in the *lower portion* of the ileum, might extend throughout the colon, but were not seen in the upper part of the small intestine.

Again, this peculiar anatomical fact was not seen in young persons, and why not? Although typhoid fever frequently occurs in young persons, the characteristic ulcerations are not found because the Peyer's patches are but little developed.

Typhoid fever is introduced by the respiratory or the digestive organs, mostly by the latter. Small children do not take water in the shape in which adults consume it, but take it either in the shape of milk or in such substances as necessitate boiling the water. It is in this manner that the organic poisons are destroyed, and thus it is that in the first place there are less changes in the intestinal tract and the symptoms are less developed in small children than in mild cases occurring in adults. This shows that typhoid fever may occur in a variety of forms, according to the accompanying circumstances.

Dr. Jacobi believed that there was such a thing as typho-malarial fever, and did not believe that it was the same disease as typhoid fever. It was a severe fever, typhoid in character, lasted longer than typhoid fever, and at the end of three weeks the fever remained, frequently relapsed; after awhile the fever became irregular; in the fifth or sixth week attacks occurred which looked very much like intermittent fever, one or even two chills occurring daily; then fever more of a remittent type manifested itself, and finally complete disappearance of the fever.

The Section then adjourned.

Correspondence.

THE MEDICAL TREATMENT OF UTERINE FIBROIDS.

To the Editor of The Medical Record.

Sir: Your abstract of the paper read by Dr. More Madden at the British Gynecological Society requires a little explanation as to the original paper to make its value really understood on your side of the water. The explanation is briefly this: that Dr. Keith, Mr. Thornton, and myself, who really may be taken to be the chief performers of hysterectomy in this country, stand, of course, on a different platform from Dr. More Madden. We do not deny, any more than he does, that a vast number, probably the greater number, of cases of uterine myoma require no kind of treatment at all, either medical or surgical; in fact, they probably are not discovered at all in very many instances. But we see a selected class of cases which Dr. More Madden is not called upon to deal with, and apparently, with the exception of three instances, he has not seen them at all. This arises, of course, from our different positions. Dr. More Madden is physician to the Mater Misericordia Hospital in Dublin, which is an institution of a purely sectarian character, in which there is no very active amount of work going on. Dr. More Madden himself has a distinguished position as a practitioner in Dublin, but a proof that he has no very special position is afforded in the fact that, after the most careful inquiry in Dublin, I can only discover that he has performed abdominal section once; that it was, very much to his credit, successful, but that he has not had an opportunity of repeating his success. Those of us already named, on the contrary, are engaged every week of our lives in operating upon the most serious class of cases—cases which are sent to us from, practically, all parts of the world. We therefore get numerous cases of a kind which, as I have said, are almost unknown, save in Dr. More Madden's experience.

Concerning the operation for the removal of the appendages for the treatment of uterine myoma, I immediately followed Dr. More Madden's paper by one which I read at the Cardiff meeting of the British Medical Association, and this, when you have seen it, I think, will be found to establish, beyond all doubt, the immense value of this particular proceeding.

I will conclude my letter by one small explanation, which is of a purely personal character. Quoting Dr. More Madden, you agree with him in what he says about my own practice, specially speaking of incompleted

operations. Thus you say, "Of these incompleted operations, Mr. Lawson Tait thinks that he may speak with a certain amount of satisfaction, though from what he derives this contentment we are, with Dr. Madden, at a loss to understand, as his mortality in them was fifty per cent." You, of course, are not responsible for this dishonest misquotation: you merely take the matter as Dr. More Madden puts it. If Dr. Madden had completed the sentence, of which he only takes a few words, he would have displayed to you and his others readers this: "Of one group I think I may speak with a certain amount of satisfaction; that is, the group which includes thirty cases of incomplete operations, even if all that I can say is that three per cent. of incomplete operations is not a large proportion, and I have the satisfaction of knowing that it is still on the decrease, as my experience grows." When this sentence of mine is completed, an altogether different aspect appears from that most improper appearance put upon it by Dr. More Madden, who tries to make it appear, as if I had some inward satisfaction in a mortality of fifty per cent., though, by the way, the mortality is not fifty per cent.

I am, Sir, yours, etc.,

LAWSON TAIT.

BIRMINGHAM, October, 1885.

New Instruments.

BINAURAL CONVERSATION-TUBE FOR THE AURAL INSTRUCTION OF THE DEAF.

DR. SEXTON stated at the recent meeting of the American Otological Society that in many instances the deaf seemed to get the best idea of the character of sound constituting the human voice when spoken to through a mouth trumpet as recommended by him many years ago; but there were a large number of deaf children who could obtain a pretty good idea of the natural sound of the voice by means of a binaural tube, whereby they may compare their own voice with the teacher's. The advantages of the binaural transmission of sound are manifest where some hearing power remains in both ears. The instrument is serviceable in teaching almost all very

deaf children or in conversing with deaf people. The sound of the voice is not so much increased by this instrument as not to be heard in a natural tone, as when spoken directly into the ear by close contact of the speaker. The painfulness of trumpets and conical tubes is thus avoided. The application and use of the instrument are well shown in the accompanying illustration. They are manufactured by Mr. W. F. Ford, of New York. [Since the instrument was shown to the Society Dr. Sexton has caused a self-retaining appliance to be attached, so that a spring holds the ear-pieces in place.]

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 18, 1885, to October 24, 1885.

MCPARLIN, T. A., Colonel and Surgeon. Directed to await further orders in New York City. Letter from A. G. O., October 19, 1885.

VOLLUM, E. P., Lieutenant-Colonel and Surgeon. Assigned to duty as Attending Surgeon, Headquarters Department of the Platte, Omaha, Neb., relieving Assistant Surgeon Wm. C. Shannon. S. O. 103, Department of the Platte, October 15, 1885.

HEGER, ANTHONY, Major and Surgeon. Directed, in addition to his present duties as Member of Army Medical Examining Board now in session in New York City, to perform the duties of Attending Surgeon in that city. S. O. 240, A. G. O., October 19, 1885.

BAILY, JOSEPH C., Major and Surgeon. Granted leave of absence for twenty days. S. O. 225, Department of the East, October 19, 1885.

Medical Items.

CONCERNING CLIQUES.—We recently encountered an old practitioner whose memory extended over a sufficient period of observation of the medical world of New York to give his words an authority worthy of recognition. He thus discoursed concerning cliques: "New York, in the early days, was under the all-powerful sway of the New York Hospital Clique, centring about the old Barclay Street Medical College. This clique was law and gospel to the profession. It held a mighty power. The ins had everything, the outs nothing. But, as is often the case, some of the profession grew restive under the somewhat arbitrary control then exercised, and questions as to rights and patronage arose. The result was the overthrow of the New York Hospital Clique, and the establishment of the clique which represented the College of Physicians and Surgeons. The Kappa Lambda Society was formed about this time. Its object was to restrict patronage in consultations and professional associations to its members. Most of the members belonged to the 'old college,' and for a time controlled the business of the then young city. It was easy for them to say that all others were wanting in respectability and standing, and there was no appeal. This sway in time gave way to the clique at the University, under the control of Dr. Valentine Mott, who stood at the head of the profession, and was the leading surgeon, not only of New York, but of the country. No one man has been able to occupy his place since. Time went on, and three powerful cliques represented the former power which was swayed by one. They were named respectively after the three colleges around which they centred, that of the Physicians and Surgeons, the University, and Bellevue. The reign of cliques is over—New York has become too large for them. Their empire, like that of the old Roman, has gone to pieces by its own weight. To-day there are feeble attempts at cliquism. Ambition is ever ready to grasp at the control and supremacy represented by them, but it cannot be said that the medical profession to-day is under the dominance of one man or set of men holding in their hands the power of life and death. *Le roi est mort;* but now no one shouts *vive le roi.* A republic has succeeded, based on the suffrage of the people. No one man in New York is accorded the title of *The Surgeon,* or the physician; the question is no longer asked in the singular; if it is, it is always answered in the plural. The leading medical societies give every member a chance to give his experience, the leading medical journals print his articles if they are worthy of it, and the field is quite

open to new-comers. It is not in the spirit of the age to tolerate cliques in professional circles, whatever may be the case in social, and it must be considered as a sign of a greater breadth of culture—a broadening of the phylacteries of knowledge. It is true, the colleges are still family stock concerns, but the next generation may change even this. Fairness and truth generally triumph in the long run. But I may tell you more about the colleges at another time."

Static Electricity.—Dr. A. L. Ranney writes: "In your issue of October 24th, two paragraphs appeared relative to my improvement of the Medical Holtz Static Machine, which demand a reply. I will answer each separately: 1. The *soft rubber packing* in the joints of my case is not claimed by Mr. Rosseau either in his letter or the advertisement which he simultaneously publishes; nor, to my knowledge, has it ever been before used in a static machine. This constitutes *my only claim to priority*. The other modifications enumerated by me are of minor importance; but they add to the general effectiveness of the instrument. An air-tight case cannot be made without some protection to the joints, against the entrance of dampness from without. 2. The criticism of the correspondent who quibbles over the chemical effects of burning alcohol in the case of a static machine, is answered *practically* by the fact that a machine will often be excited to action during damp weather by the heated air thus produced, when it will not work under other circumstances until the air is dried by fresh calcium. This is not always at hand. There is a distinction to be drawn between a temporary lift out of a difficulty and a recommendation of such a step as the best way of overcoming it. This criticism is evidently not made by a practical man. As far as I can ascertain, it is a difficult matter for Mr. Rosseau or any other manufacturer to establish *priority for any new principle* in his machine built on the Holtz model or the Toepler model. I think any fair-minded reader will acquit me of a desire to do any one injustice or to claim priority for any part of my model outside of the *soft rubber packing used to make its joints impervious to air*. Even this may have been done before, but, if so, I am not aware of it. I will gladly waive all claim even to this improvement when convinced that I am in error."

Physicians' Commissions from Druggists.—Dr. Richard B. Faulkner, of Allegheny, Pa., sends a letter commenting upon the subject of physicians' commissions from druggists. At the recent meeting of the American Pharmaceutical Association, at Pittsburg, Mr. J. W. Colcord, of Lynn, Mass., read an extract from a San Francisco letter, which asserted that pharmacists are compelled to pay sixty per cent. of the *gross* receipts as commission to the physicians who patronize them. Dr. Faulkner was assured by Professor John M. Maisch that Mr. Colcord's statement was openly made and corroborated by Professor Painter, who added that such cases were common, "not isolated; and that the leading druggists of San Francisco pay to the leading physicians, in money, sixty per cent. of gross receipts." Mr. Whelpley, of the *National Druggist*, said, "Percentages are given in St. Louis, and in different ways; for example, druggists would fit up physicians' offices." Our correspondent avers that this practice of giving percentages does not exist in Allegheny.

Gerhardt's Treatment for Lupus.—Gerhardt has lately employed a treatment for lupus that appears to be very valuable. He applies ice-bags to them during the greater part of the day. He recently showed four cases that very entirely healed over by a very fine elastic scar. He got the idea by arguing that, since lupus is produced by the tuberculosis bacilli, and since the activity of these is greatly diminished by cold, by the employment of this his patients might be more benefited than by any other measure. Of course the spores of the bacillus are not so easily affected; but such objections are always to be found in every kind of treatment. That cold, continuously applied, penetrates inwardly, he has demonstrated by taking the temperature in both sides of the mouth after the ice-bag had been applied to one of the cheeks for some hours. He found the difference to be as much as 3° C. in some cases. The attained results certainly speak well for the method.—*Medical Press of Western New York.*

In Severe Cases of Lumbago, Professor Da Costa advised acetate of potassium, ℈j., four times daily, to be dissolved in syrup. He gives also morphine and atropine.—*C. and C. Record.*

The Ancient View of the Value of Digitalis.—In "The English Physician," 1656, by Nich. Culpeper, a chapter is given on the uses of digitalis (*Lancet*). After giving a botanical description and the habitat of digitalis, Dr. Culpeper goes on to say: "The Plant is under the Dominion of Venus, being of a gentle clensing nature; and withal very friendly to Nature. The Herb is familiarly and frequently used by the Italians to heal any fresh or green Wound, the Leavs being but bruised and bound thereon; and the Juyce thereof is also used in old Sores, to clens, dry, and heal them. The Decoction hereof made up with some Suger or Honey is available to clens and purge the Body, both upward and downward, sometimes of tough flegm and clammy humors, and to open obstructions of the Liver and Spleen. It hath been found by experience to be available for the King's Evil. The Herb bruised and applied, or an Oyntment made with the Juyce thereof and so used, and a Decoction of two handfuls thereof with four ounces of Polipody in ale, hath been found by late experience to cure divers of the Falling-sickness that have been troubled with it above twenty years. Myself am confident that an Oyntment of it is one of the best Remidies for a scabby head that is."

Last year the number of medical and pharmaceutical students who completed their curriculum at the universities of Spain was 703, the total number of students graduating being 3,598.

It is reported in the Bombay Season Reports that on December 27th last seven shepherds lost their lives at Athni, in the Belgaum District, through being struck by hailstones of the size of a cocoanut.

The Odor of New Paint and Abortion.—Dr. Charles H. French, of Waterbury, writes that he has, on two occasions, recently been consulted by patients who were in the seventh month of pregnancy, and who desired to move into a newly painted house. They desired to know whether there would be any danger of abortion being caused by the odor of the new paint, as popular opinion asserts. Dr. French has been unable to find any medical authority for this belief, and is desirous of learning what is the experience of others in the matter.

One Can Quote as Well as Another.—"Measure for Measure," as the patient said when he poured out ℥ij. of turpentine for his tape-worm. "All's well if this end is well," said the tape-worm, as he buried his front end in a follicle of Lieberkühn while the turpentine swept by.

The new Idea in Nostrums is not to pretend that a particular medicine will cure all maladies, but will positively and completely cure the one disease for which it is designed. The clear-sighted student of human nature who discovered this slant is said to be on the road to a fortune.

Controversial.—

Said Koch: "I've some comma bacilli."
Said Klein: "I don't think they will kill." "I"
Said Finkler (and Prior),
"Believe he's a liar."
Said Ferrán: "I can knock you *all* sill i."

The Medical Record

A Weekly Journal of Medicine and Surgery

Vol. 28, No. 19 NEW YORK, NOVEMBER 7, 1885 Whole No. 783

Original Articles.

SUMMARY OF ONE HUNDRED AND SEVENTY-EIGHT CASES OF TYPHOID FEVER.

By EDWIN T. DOUBLEDAY, M.D.,

MEDICAL CLINICAL REGISTRAR TO THE NEW YORK HOSPITAL.

THIS summary comprises the cases of typhoid fever treated in the New York Hospital (new building) from April, 1877, to January, 1885. The following symptoms were taken as marks of the commencement of the disease: chilly sensations, diarrhœa, frontal headache, epistaxis, or pain in the bowels. In cases where all these were absent, or not stated with sufficient accuracy, the time at which the patient took to his bed is taken as a date on which to base calculations.

Number of cases, 178; males, 125; females, 53.

R. = recovered; D = died.

AGE.	R.	D.	Total.
5 to 10 years	2	....	2
10 to 15 years	3	....	3
15 to 20 years	24	5	29
20 to 25 years	57	10	67

NATURE OF CASES.

	Males. R.	Males. D.	Females. R.	Females. D.
Uncomplicated	73	9	23	6
Complicated	34	9	18	6

Relapse occurred in 33 cases; males, 19, = 15.2 per cent.; females, 14 = 26.4 per cent. In five cases there was more than one relapse. Average duration of the relapse: males, 12.88 days; females, 12.95 days. In 9 of the 33 cases of relapse the cause is stated to have been sitting up too early in convalescence. Constipation is supposed to have caused a relapse in 4 cases, and in 1 case the relapse followed an attack of gastric dyspepsia. In 19 cases of relapse no assignable cause could be discovered. None of the cases complicated by a relapse were fatal.

Frequency of Symptoms.—Diarrhœa occurred in one hundred and fifteen cases. Average time of occurrence was the 5.5th day of the disease.

Eruption was observed in ninety-six cases. Average time of appearance was the twelfth day of the disease. The eruption appeared in sixteen cases on the seventh day; in fifteen cases on the fourteenth day; in seven cases on the eighth day, and in six cases each on the fifth, tenth, and twelfth days. Epistaxis occurred in fifty-seven cases. In fifteen cases it occurred more than once. In over a third of the fifty-seven cases epistaxis occurred on the second day of the disease.

Delirium occurred in forty-six cases. Of these forty-six cases twenty-six recovered and twenty died. Of those who recovered the average time at which delirium first appeared was the 13.5th day of the disease. Of those who died the average time of its appearance was the 15.5th day of the disease.

Complications.—Bronchitis occurred so often, and almost invariably at the end of the first or beginning of the second week, that one is tempted to regard it more as a symptom than a complication. It occurred in nineteen cases.

Six cases were complicated by phlebitis. The times of appearance and the situation were as follows: Right femoral vein, on the thirtieth and on the fifty-fifth day; left femoral vein, on the eighteenth and on the thirty-third day; left popliteal vein, on the thirty-third day; right brachial vein, on the sixty-second day.

Abscess complicated seven cases. The abscesses were situated as follows: Perineal, ischio-rectal, left hypochondriac, right arm, both inguinal, left submaxillary, and right parotid region, followed by multiple abscesses. In five of these cases the abscesses were sequelæ rather than complications. One patient (case seven) had thirteen abscesses. He had a chill at the end of the fourth week of the disease, and the temperature ran up from 99° to 103.5°. Examination showed some induration and swelling of the right parotid gland; this was opened on the following day. Subsequently twelve abscesses were opened. These were on the back, gluteal region, inguinal region, malar region, parotid (left), and both submaxillary regions. After the first chill there were only two rises of temperature, and only five of the abscesses gave noticeable pain. These five were situated where pressure was made on them. Some of the abscesses were only detected by daily careful examination of the whole body. Various dressings were tried on the abscesses, among them balsam Peru, zinc oxide (dry and in ointment), salicylic acid, bichloride gauze, boracic acid solution, carbolic dressing, and iodoform. The abscesses treated in the following manner healed quickest: free incision, washed with carbolic acid solution (1 to 40), small amount of iodoform dusted in the cavity, outside an iodoform compress and pressure, and approximation of the edges secured by means of strapping. Abscesses treated in this way healed almost entirely by first intention, notwithstanding the patient was very weak and had extensive bed-sores.

Otitis media suppurativa occurred in three cases.

General furunculosis followed the fever in eight cases, in seven of these cases it came on in the fifth week.

Hemorrhage (intestinal) occurred in twelve cases at the following time: Third, seventh, tenth, twelfth, fourteenth, eighteenth, nineteenth, twentieth, forty-seventh, and forty-ninth days, all cured; on the thirteenth, twenty-seventh, fourteenth, twenty-ninth, thirtieth, and thirty-ninth days, all died.

Three cases were complicated by cystitis. In these the patient had not been catheterized. In one case there was profuse hemorrhage from the uterus and from the vaginal mucous membrane.

Retention of urine was observed in twenty-two cases. In one case it came on in the first week, in eleven cases in the second week, and in ten cases in the third week.

In thirteen cases there was albumen, hyalin, and granular casts in the urine. Of these thirteen cases seven recovered and six died. In five cases the urine contained albumen with hyalin casts, of these four recovered and one died. In thirteen cases the urine contained albumen without casts. Of these eleven recovered and two died.

Lobar pneumonia complicated seven cases; five recovered and two died. Herpes occurred in the fourth week in two cases; both recovered. Bed-sores occurred in two cases only; both recovered. Periostitis (syphilitic?) occurred in two cases.

Mania, meningitis, tonsillitis, acute parenchymatous nephritis, acute rheumatism, persistent vomiting, persistent nausea, each complicated one case; all recovered. Catarrhal pneumonia, purulent bronchitis, abscess of the lung, and perforation of the intestine, each occurred in one case; all fatal. Tuberculosis complicated two cases; both fatal.

Infection.—In four cases there were other cases of typhoid fever in the house. In two cases the patients had been nursing persons sick with typhoid.

Temperature.—In four cases the temperature reached 107°; three recovered and one died. In eleven cases the thermometer registered 106°, or over. Of these three recovered and eight died. In forty-six cases the temperature reached 105°; thirty-five cases recovered and eleven died. These figures are exclusive of antemortem rises of temperature. In two cases death was preceded by a marked fall of temperature. The fall was 2° in one case and 5° in the other case. No hemorrhage in either case.

Treatment.—As few of the cases were similar in anything but their temperature curves, and the sets of cases belonging to different years varied much in their severity, it is a difficult matter to make any comparisons of the efficacy of the different plans of treatment employed. For feeding, milk, milk-punch, eggnog, peptonized milk, and beef-tea were used. Almost all the cases of 1883 and 1884 were fed on peptonized milk until the subsidence of the fever. For stimulants, brandy, whiskey, tr. digitalis, inf. digitalis, and occasionally ammonium carbonate were used. For reducing temperature, quinine, antipyrin, cinchona, kairin, alcohol sponge baths, cold baths, and the wet pack, singly and in combination, were used. Quinine and antipyrin were the drugs used most frequently alone. Quinine alone was used in forty-six cases; forty-three recovered and three died. Antipyrin alone was used in twelve cases; eleven recovered and one died. Kairin alone was only used in three cases; two recovered and one died.

Various remedies directed at the disease itself have been tried, such as bichloride of mercury, tr. iodine, carbolic acid, oil of eucalyptus, and calomel, but the cases are too few for any conclusions as to the best treatment to be reached.

A Large Ventral Hernia.—Dr. Samuel W. Francis, of Newport, R. I., reports a case of ventral hernia in which the measurements for a truss were as follows: circumference at the top, 41 inches; at the middle, 55 inches; at the bottom, 50 inches; length from above downward, 24 inches.

A SKETCH OF THE LIFE OF JAMES LAWRENCE LITTLE, M.D., AND OF THE TWENTY-FIVE YEARS IN WHICH HE PRACTISED SURGERY IN NEW YORK.[1]

By D. B. ST. JOHN ROOSA, M.D.,

NEW YORK.

James Lawrence Little was born of Scotch-Irish and English ancestry, in the city of Brooklyn, February 19, 1836. He attended private schools in his native city until he was about twenty years of age, when he attempted to become a bookseller, and for this purpose became a clerk in a Fulton Street establishment kept by Mr. Riker. The firm that engaged him had a stock of medical books as well as of general literature. The young clerk was soon so deeply engaged in the study of these books that he proved a very inefficient salesman, and he gave up his attempt in business.

This inclination to the study of medicine had already been seen in young Little when he was a mere boy. After much cogitation as to the ways and means of getting a skull for the purpose of study, he finally approached a venerable African grave-digger, who consented to furnish him with the desired relic, if he would bring twenty-five cents and a paper to wrap it in. Little secured the treasure on these terms, and returning home, took a peep at it, and, to his youthful horror, found that it was an unprepared skull looking upon him in the ghastly covering of facial integument and scalp. Fear got the better of his anatomical enthusiasm, and seeking a plan to get rid of what was now a source of dread at its horrible aspect, as well as of fear lest he might be found with such an unexplainable object upon him, he threw it into the waters of Wallabout Bay, and postponed his medical studies for a season.

After leaving the bookstore Little entered the office of Dr. Willard Parker as a private student, and at the same time he matriculated in the College of Physicians and Surgeons. After Dr. Little had become a distinguished surgeon, Dr. Parker gave the writer an account of how he nearly rejected him when he applied for entrance to his already crowded rooms. He was at first disposed to decline to receive another student, but he was impressed by the great earnestness of the tall and handsome young man, and he consented to take him. "But," continued Dr. Parker, "I never had occasion to regret my decision. Punctually as the clock struck nine, the click of the young man's boots was heard upon the doorstep, and I got to recognize his step and to count upon him whoever failed." The word *click* aptly describes the short and quick step that many of Dr. Little's contemporaries will recall as one of his personal characteristics.

After being in Dr. Parker's office more than two years, he successfully passed a competitive examination, and was appointed a junior assistant in Bellevue Hospital. This appointment did not take effect until the following spring. Meanwhile, in March, 1860, he was graduated at the College of Physicians and Surgeons. He then resigned his position at Bellevue, and after examination he was appointed junior assistant in one of the surgical divisions of the New York Hospital. A resignation of a place in one hospital to take a similar one in another was something unusual, and it was said at the time that it caused a little unpleasant feeling among the staff at Bellevue, for Dr. Little was well known to some of them, and to James R. Wood in particular, as a promising man whom it was not well to lose.

Bellevue Hospital was just coming into some importance as a school of surgery, and chiefly through Dr. Wood's clinics and his prizes for anatomical preparations offered for competition among the medical schools. Yet at that time it could in no manner compare with the New York Hospital in furnishing opportunities to a surgical student. It was an institution belonging to the city,

[1] Read before the New York Academy of Medicine, November 5, 1885.

receiving only paupers to its wards, and it was governed by politicians. It had much more importance as a school of medicine than as one of surgery. Dr. John W. Francis was one of its consulting physicians, and occasionally gave a mellifluous and learned address in its amphitheatre, and Alonzo Clark, John T. Metcalfe, and Benjamin W. McCready held clinics in the wards, while on Saturdays there was a great crowd of students to witness the rapid and skilful surgical operations of the renowned pupil of Valentine Mott, James R. Wood. Certainly any young doctor in medicine might have been honored by entrance into such a hospital. But the New York Hospital was a wealthy and private corporation, governed by some of the best laymen in the city, and, more than all, it was one of the most renowned schools of surgery in the world. In its amphitheatre Wright, Post, and Kearney Rodgers had won their fame, and here Valentine Mott, who was still living and lecturing upon surgery, had tied the *arteria innominata*. He was consulting surgeon with Alexander H. Stevens, John C. Cheesman, and Alfred C. Post. Of these but one now remains, an honored link to connect us to the medical New York of fifty years ago. The active members of the surgical staff were Gurdon Buck, John Watson, Thaddeus M. Halsted, Willard Parker, William H. Van Buren, and Thomas M. Markoe. Of this number but one now survives, and he happily in full vigor of mind and body. The old hospital was beautifully situated on Broadway, facing Pearl Street, on ample grounds, with grand old elms. Its beautiful lawn, upon which tame deer might often be seen, was a surprise and delight to the strangers in New York, who came suddenly upon this break in the whirl of a great city.

The house staff was in a traditional state of excellent discipline. Its members vied with one another in their care of their cases, and their dressings of fractures and ulcers were at once the delight and dismay of medical students, who followed the attending surgeons about the wards. It was not strange, then, that young Little, especially when urged by his preceptor, resigned his place in a hospital which had no past, for one whose annals, twenty-five years ago, were more full than perhaps any surgical hospital in the land.

In April, 1860, Dr. Little began his duties at the New York Hospital as a junior walker. In April, 1885, he died. Hence, it may be truly said that a quarter of a century bounded his professional career. What a twenty-five years it has been for medical and surgical science in New York and in the world! There were then three colleges, and perhaps eight hundred students and practitioners attending lectures in the College of Physicians and Surgeons in Twenty-third Street, the University in Fourteenth Street, and the New York Medical College in Thirteenth Street. Bellevue Hospital Medical College existed only in the embryo of its medical clinics and James R. Wood's exploits on Saturday afternoons. Clinical instruction was in its infancy, and there were but two hospitals, at long distances from the colleges, where it may be said to have existed in a meagre way, and then to be attended by not more than a score or so of the students, except when a great operation was to be performed. Now there are added to the New York and Bellevue the great Charity Hospital on the Island, St. Luke's, the Roosevelt, the Presbyterian, Mount Sinai, and St. Vincent's; these are all more or less used for clinical teaching, and eighteen hundred or more students and physicians attend the lectures of the three colleges of our faith, the College for Women, the Post-graduate School, and the Polyclinic.

Among the most widely known of the teachers at the Colleges were Parker, Gilman, Watts, St. John, and Joseph M. Smith, in Twenty-third Street; John William Draper, Bedford, Paine, Van Buren, Post, and Metcalfe, at the University; Horace Green, Fordyce Barker, Ogden Doremus, and Carnochan, in the New York College; while George T. Elliot, Charles A. Budd, Loomis, Jacobi, Thomas, Sands were, as would be said in Edinburgh, *extra-mural* teachers, who were nearly within the walls. So great have been the losses by death in these names, that, as we recall them, the words of the Latin poet come at once to the mind:

> "Eheu fugaces Postume Postume,
> Labuntur anni."

When Dr. Little entered the New York Hospital the civil war had not broken out, although exciting meetings of students had been held on account of the John Brown raid, and Southern students were being pledged not to return to Northern cities for instruction. Terrible strife was soon to cause the erection of immense hospitals by the medical staff of the United States army, from whose records surgical literature was to be enriched to an extent not dreamed of by the surgeons of this country. The battle-fields of Manassas, Shiloh, Gettysburg, and around Richmond, were, from their awful experiences, to train a race of men which has caused American surgery and medicine to take a higher place in the world than would have been attained by half a century of work in small civil hospitals, while the Sanitary Commission was to open up a field for the cultivation of sanitary science and of active benevolence hitherto unknown.

When Dr. Little entered the wards of the New York Hospital, the thermometer was not used to show the temperature of the body. The laryngoscope and ophthalmoscope had just been placed in the hands of a very few specialists, but they were not at all employed in the New York general hospitals.

There was but one hospital of any considerable importance for diseases of the eye and ear, and that had not one-half the number of patients it now has, although three similar institutions have been added to the charitable and educational resources of the city. There were no training schools for nurses, and scarcely any trained nurses worthy the name. Those whom we had were chiefly males, with a strong preference for alcohol as a stimulant, who had been promoted from being patients to be nurses, while the women, in many instances, had been scrubbers in the wards over which they now presided. Not but that there were some excellent nurses in those days, however. Pyæmia, erysipelas, and hospital gangrene were then dreaded foes, and antiseptic surgery, if practised in attempts at absolute cleanliness, was not understood as now, when patients, after operations, are saved, not as by fire, but as a matter of course. Marion Sims had just read his famous paper before this Academy upon silver sutures in surgery, and was about to found the Woman's Hospital and become the intellectual progenitor of men who with him created modern gynecology. All this Dr. Little saw, and in much of it he was an active participant.

New York, in 1860, had two or three medical journals, not of extended circulation, while an Ishmaelitish scribbler or two issued monthly bulletins in a style of medical journalism now happily extinct. There were two medical bookstores, called publishing houses rather by courtesy than as a matter of fact, for scarcely a New Yorker but Bedford and Dalton and Draper had written a medical book, and very few had even edited or translated one. New York scarcely claimed equal rank with Philadelphia as a medical centre.

Now, New York boasts three publishing houses where American medical books are issued, and that in considerable number. Her medical journals are more widely circulated than those of any other city in this country, and they are to be found by the side of the works of American medical men upon the library tables of the physicians of every nation.

In the hospital Little gave promise of his future career. He was assiduous and faithful as an assistant, and suggestive and enthusiastic as a house surgeon. His humorous contemporary, Dr. Samuel W. Francis, remarked of him that even then there was *multum in parvo*. He reported many of the cases occurring in the wards in the

American Medical Times. It was while in the hospital that he devised his method of making and applying plaster-of-Paris splints. It is not too much to say that chiefly, if not entirely, through Little's efforts plaster-of-Paris splints became a practical application. Until then, although much recommended, experience had shown that it was not well adapted for a surgical dressing. Little saw in plaster-of-Paris a material which, if properly used, would form that so much to be desired, an immovable and yet porous splint. Those of us who were associated with him remember his painstaking trials in preparing the plaster, in securing the proper consistency, and the material best adapted to take up the solution, the disappointments and failures until a splint was produced which convinced his colleague, the house surgeon of the other division, and the attending surgeons, that the days of the starch apparatus—a favorite bandage of the hospital—were past. In using plaster-of-Paris as a splint instead of a bandage, he utilized the material as never was before done, and although it is possible that it will never have a widespread use, just as Dr. Little employed it, he gave an impetus to the subject which was perhaps the origin of the famous plaster-of-Paris jacket. His paper upon the subject may be said to be classical.[1]

During the civil war, on several occasions, Little's services were furnished to the Government. He was for a time surgeon-in-chief to the hospital erected on the edge of the City Hall Park, and twice, at least, after great battles, he volunteered with those other New York surgeons who went to the front at the call of Surgeon-General Hammond. Now, as then, the avenues to professional success as a teacher and consultant began at service in dispensaries and clinics. Dr. Little was engaged in such work from the days when he was a medical student and a *substitute* for the junior walker in the hospital, until his death. One year after leaving the hospital he was appointed clinical assistant to Dr. Parker, who was then Professor of Surgery in the College of Physicians and Surgeons. In 1863 he was appointed a Lecturer in the College. His first course of lectures was upon "Fractures and their Treatment." These lectures were continued until 1868, when his chair was enlarged to that of "Operative Surgery and Surgical Dressings."

Dr. Little was very popular as a lecturer. His manner was exceedingly simple, in fact, at first distressingly so; but it was earnest, and devoid of mannerisms and self-consciousness. One of our most successful teachers lately said to me, "Little did not merely tell the men to apply a flaxseed poultice, but he brought the flaxseed and the cloth to the lecture-room and made the poultice before the class. Then they knew how it was done, for they had seen it." Indeed, his teaching was realistic to a degree. The man was thoroughly in love with his work. He was alive to every progressive tendency; he travelled in no rut, but was always on the alert to assist in making surgery the exact science it is so fast becoming. He took great pains with the illustration of his subject by diagrams and drawings, which were prepared by competent men under his directions with great care. An examination of his library after his death showed that he had ransacked the surgical pictures of Great Britain and the Continent to secure the best illustrations for his lectures. Certain it is, that not a little of the fame of his alma mater for thorough teaching was due to Dr. Little's lectures, although they were given in the summer term, and attendance upon them was not obligatory. They were continued for sixteen years, when he resigned from the position he held in the college as a lecturer on surgery, and one of the staff of Professor Markoe—who has succeeded Parker—and accepted the appointment of Professor of Clinical Surgery in the University of New York.

But Little's best qualities as a surgeon, a teacher, and an executive officer were seen after his appointment to the chair of surgery in the University of Vermont. This was in 1875. He had previously declined an offer of a similar chair in the Long Island College Hospital. He entered upon the work in Burlington with great zeal. There he found a medical college that still survived the vicissitudes of forty years, although those at Woodstock and Castleton, in the same State, had been abandoned. It had about sixty students. Little's keen perception of the possibilities of this field showed him that they were great. The lately elected President of the University, Dr. Buckham; the venerable Carpenter, professor of practice; with Thayer of anatomy, King of obstetrics, and Darling of anatomy, were fully alive to what lay in store for the Burlington Medical College. There was a reason for the existence of a medical college there. It was needed to supply the demand for medical education for a large number of young men from Vermont and Northern New York, who could not conveniently go to Boston, Philadelphia, or New York.

The academical department, at the laying of whose corner-stone Lafayette had assisted, embraced in its faculty many soundly educated and cultured men, whose sympathies were readily enlisted for any good scheme for the cultivation and dissemination of human knowledge. They seconded the efforts of the president to give character to the various departments. The medical school acquired a certain dignity by its name, and it had that not unimportant advantage over the schools that formerly existed in the same State. Many young men, exceptionally well prepared by previous training, found it more convenient to study in Burlington, on account of the greater expense attending a long stay in a large city; and many practitioners of Vermont and Northern New York found the clinics and lectures of the medical department of the University an accessible post-graduate school, which lighted up many a dark subject, and gave them a little recreation from their lonely and responsible duties as country physicians. The professor who went to Burlington from a metropolitan medical college soon saw that he had as intelligent and as earnest listeners as at home, and that he must relax nothing in his efforts to teach his science and art. With the hearty co-operation of the President of the University, who presided at all the faculty meetings, and his own colleagues, Professor Little immediately began to devise plans for increasing the fame and usefulness of the school. By personal solicitations in many instances, he was largely instrumental in securing courses of lectures and clinics upon subjects not fully, if at all, embraced in the general curriculum, by specialists from colleges in our city. Then, Miss Mary Fletcher, acting largely upon the advice of President Buckham and Professor Carpenter, founded a hospital, and with a broad-mindedness not always seen in those who found hospitals, gave up its wards unreservedly to the teachers of the college. This was naturally of the greatest importance to the success of the school, for the day had passed when didactic lectures, unillustrated by subjects, were considered fit means of teaching medicine and surgery. Little's facilities for the performance of great operations were largely increased by the foundation of the hospital. His clinics were sought by crowds of patients from far and near. During the weeks that he lectured in Burlington the streets of the city gave evidence, by the passing through them of numerous people with surgical dressings on some part of the body, and by the great accumulation of the mud-stained buggies of the practitioners of the adjacent towns, as well as by the overfilled wards of the hospital, that a great deal of surgical work was going on. Stimulated largely by Little's surgical feats, and by an executive capacity heretofore, from the want of an arena, not known to belong to him, the college grew apace in character, importance, and in the number of students. A new building was given to the faculty in 1884, by the late Mr. Howard, and when Dr. Little died, more than two hundred and twenty students

[1] Transactions American Medical Association, 1867, MEDICAL RECORD, 1874.

in the class-rooms of the college mourned the loss of their professor of surgery.

In an address commemorative of Darling and Little, Professor A. F. A. King sketches the introduction of the latter to the class in a manner so graphic and descriptive of the man that it is here reproduced. Dr. King says: "I introduced him to the class, and I well remember his modest embarrassment, which would, however, have passed unnoticed by the students, had he not said in the course of his first disjointed remarks, 'I'm a little nervous, as you see.' But a patient was introduced, a diagnosis made, an operation decided upon, and a knife handed to Professor Little, and I can tell you (as you know) he was not nervous *then*."

To those of us who knew Little well, it was interesting to see this preliminary nervousness when a great operation was imminent. The quick, short steps, the restless tapping of the foot when he was preparing for his work, gave little promise of the bold, self-reliant man as he stood over the patient, perhaps reeking with the perspiration of surgical ardor, but yet with steady, skilful hand working in a manner that convinced any one competent to judge, that a life given into his care would be preserved and returned, were it among human possibilities.

In Burlington as in New York, "Little's luck" became proverbial, for his operations, from causes that I am not able to analyze or define, were pre-eminently successful. A well-known surgeon in New York told me, in substance, that it was a prevalent opinion in St. Luke's Hospital, that it would be safe for Little to cut off a foot of an intestine, when another man could hardly touch it with a knife; and yet he was deferential to a fault to the surgical opinions of his peers, ready to adopt their suggestions, and to give proper credit for them. He was a man who exhibited great common-sense as a surgeon. He was not overtrained, but he knew how to get at the upshot of a case without being unduly anxious as to how Esmarch or Lister were doing that thing now.

Dr. Little's chair in the University of New York was never fully satisfactory to him. His clinics there were held but for a part of the session, and he taught but once a week, although his classes were large, and the students, at least on one occasion, petitioned the faculty that his instructions might be continued throughout the session. The request could not be granted, on account of the pressure for time in which to give the whole curriculum. Three years after his acceptance of the position, together with six members of the former post-graduate faculty of the University, he resigned, in order, in conjunction with them, to establish the *New York Post-graduate Medical School*. To this institution he gave the same hearty effort that he displayed in Burlington. His lectures to graduates were, if possible, better appreciated than by the under-graduates whom he had instructed since his early manhood. A doctor was to him a brother. Without quite knowing it himself, he acted as if he supposed that every man who sought or had acquired the degree of M.D. was as eager and honest in the pursuit of knowledge with which to save life and mitigate disease as he was himself.

It is said that he always leaned toward the student, and possibly too much, when required to vote upon an examination in the faculty at Burlington. This was not from any idea of lowering the standard of proficiency, but because he could not be made to understand that there were men who regarded medicine as a business, in which they were willing to embark with as little capital as could make a fair show. During these last three years he exhibited his best qualities of faithful work, and if, as Dr. Lloyd, one of his former office students and valued assistants, says, "he was inclined to throw off his work on other shoulders, and less inclined to undertake long and serious operations," on account of some grave symptoms in his general health, it was not apparent to those of his friends who saw him only at intervals. The last public work he was engaged in was a meeting of the Post-graduate Faculty, on the evening of March 31st, when he appeared in his usual health and spirits. At that meeting an incident occurred which was characteristic of the man. He felt impelled by his judgment to vote, on a question which then came up, contrary to his feelings. It was a question that might affect the interests of some to whom he was attached, and after he had voted and he was found to be in the majority, he expressed his regrets that he should be obliged to vote for a policy which might prove detrimental to the interests of a friend, and he vainly sought for a compromise upon the subject.

Dr. Little's services to St. Luke's Hospital were very great, and they were warmly appreciated by his patients, his colleagues, and the management. He served one term of ten years, from 1868 to 1878, when he was retired under the rules to be made a consulting surgeon. In 1882 he was reappointed an attending surgeon, and held the position until his death.

Little used to tell a story of an experience of his at St. Luke's, which well illustrates the maxim that "all men think all men mortal but themselves." He was to operate, on one afternoon, upon two cases for resection of the upper jaw. The first patient died upon the table from getting blood in the trachea, and Little sent word to the survivor that he wished to postpone the operation for him. He was very much disappointed at the delay, and urgently insisted that Dr. Little should personally visit him in the ward and tell him why he did not wish to operate upon him as appointed. The surgeon accordingly went up, and with some hesitation, on account of the probable effect upon the hopes of the candidate for an exsection, frankly told him that the first man was dead, and he did not feel like going on with a case of the same kind just at the moment. But instead of being daunted the patient exclaimed, "Oh, that's nothing! I'm not afraid. The other man was a sickly fellow. I never thought he would get through. You operate on me, I won't die." As a matter of fact Little did soon operate upon him, he got no blood in his trachea, and he did not die.

In 1876 Dr. Little was appointed an attending surgeon to St. Vincent's Hospital, a position which he held when he died. Little always believed that the kind offices of the Rev. Vicar General Quinn, one of the managers of that hospital, were largely instrumental in securing him this position. The Vicar-General was a priest in the wards when Dr. Little was house surgeon in the New York Hospital, and in his visitations to the sick and dying in the wards, had been struck by the commanding presence, the assiduous and faithful labors of the young surgeon.

Of Dr. Little's surgical achievements in detail, I am not competent to speak, nor is it necessary that I should do so. They are indelibly recorded in surgical literature—at least in part, for of late years Dr. Little was somewhat regardless, from lack of time perhaps, from his large and exacting public and private practice, to write as much as his friends might have wished. But I may say that he was the first American surgeon to puncture the bladder with the aspirator for the relief of retention of urine. He simultaneously ligated the subclavian and carotid arteries of the right side, for aneurism of the first part of the subclavian. The operation for stone by various methods he had performed seventy-seven times, with a fatal result in but two cases. In hare-lip and strangulated hernia he also had a large and successful experience.

He entered into the advances claimed to be made by antiseptic surgery with great enthusiasm, and on his last visit to Europe, at the meeting of the International Congress in London, he investigated Lister's methods very carefully, and came back to carry out all the details of Listerism in capital operations.

He was a surgeon who looked round upon a far

horizon. Very few operations were foreign to his knife. Yet he was extremely appreciative of specialists, and while not needing their advice as much as some of those who have looked askance at them, he frequently sought their aid, and often publicly recognized their value in enlarging the field of exact knowledge. He himself used the ophthalmoscope, the laryngoscope, and other means of examination not always used by general surgeons, so that he was singularly competent to make an examination in any surgical case. In the practice of medicine also—for he by no means confined his work to surgery—he was suggestive in the matter of treatment, and had many celebrated prescriptions upon which he drew with great readiness and accuracy.

Little was a great admirer of his instructor, Willard Parker. He gave his first-born the name of his preceptor. Dr. George Shrady styles him one of his worshippers. So great was this admiration when he left the hospital, that some of his friends feared he would be content to be an imitator and never strike out for himself. He seemed to have acquired Dr. Parker's art of making surgery fascinating to students; he drew them about him in great numbers. Even if the clinical material for his hour, on any particular day, was scanty, the lecture would not betray the want, for what was there was made the subject of homely but important lessons. The capacity for dignifying the everyday work of surgical practice, for making apparently minor things and details assume their true importance, belonged to him in a great degree. He could make a good clinic from material which some surgeons would not deign to spend a moment upon. Like Willard Parker also, he attracted to himself numerous office students, who almost invariably became much attached to him.

Dr. Little was, in the good sense, a simple-minded man. He loved to sit down in such places as the office at the hotel in Burlington, and, as he became warmed in his discourse, talk to plain laymen, who understood but half of what he said, of tumors and ligations, of resections and ovariotomies, and all without any idea of boasting of his own deeds, for he had not the faintest resemblance to a braggart, but he was so interested in surgery that, like Agassiz, who talked about his study of the skeletons of fishes to stage-drivers, he fairly bubbled over upon the subject. He was fond of the meetings of the profession. Since its foundation, the New York Surgical Society was his favorite place for recounting his experience, and listening to the discourse of the distinguished men who organized and maintained this body.

He was one of the signers of the address to the profession of the State against the re-enactment of the Old Code, and the movement to sustain the Medical Society of the State had his full sympathy and co-operation.

Social to a degree, he could be found late in the afternoon, in the conversation-room or at the monthly meetings of his club, with a cigar for himself and for his neighbor, ready to discourse upon any subject that was uppermost in men's minds.

He gave great thought and spared nothing in the education of his two sons and a nephew. He had almost exaggerated ideas of the importance to a young man of an exact and thorough course of study in a college. He did not practise his profession with an idea of amassing a fortune, but he conceived that it was better to thoroughly educate his sons than to leave them the few dollars which a niggardly economy might have allowed a physician dying in middle life to put aside from his professional income. Before his death he had the great satisfaction of seeing his eldest son fully equipped and prosperously entered upon the practice of a lucrative profession. In his latter years he interested himself very much in the study of china and bric-a-brac. It became a recreation to him to visit auction rooms, and he often came away with a rare bit of some kind.

Galton describes a certain class of men as being incapable of advancing beyond a certain point in mental attainment, just as another class can only be developed physically to a certain inferior standard. Little was not one of these. As long as he lived he grew in mental capacity.

He was never satisfied with his own preparation for the study of medicine; but while he did not enjoy the advantages of a college training that he appreciated so highly in others, he had that which no conventional curriculum can of itself furnish—a receptive, inquiring, and unbiased mind in science; and as to merely scholastic attainments he might have well said as did John Hunter, when he heard that he was reproached by a rival with being ignorant of the dead languages, "I would endeavor to teach him on the dead body that which he never knew in any language living or dead." It has been said by one biographer of Dr. Little that he was a typical American. It is certainly true that his career is a striking example of how eminence in our profession may be attained by the resources of our own country. His education was wholly obtained within his own city. He had none of the advantages so useful to the best of men, so without use to many, which are to be obtained in British or Continental schools. But no man more than he appreciated the labors of foreign surgeons and pathologists, no one followed more eagerly the medical literature of his time; but he was fortunate enough never to acquire such a slavish esteem for the opinions of books that he ceased to think for himself.

The sense of humor was fully developed in Dr. Little. From the busy, and sometimes weary life of a general practitioner, and from the society of his friends, he extracted much to give zest to his work. A joke at his own expense was almost as welcome as if for another. He used to tell with great glee, and awaking much laughter as he did so, how a little trick of his to stop too prolix patients once got him into great trouble. He said that he had found a good device for interrupting a needlessly long story on the part of a patient was to ask, in the midst of the long narrative, "Please let me see your tongue." He found that patients bore this interruption very well, and that in their eagerness to get the doctor's opinion of this index of the digestion, its wagging ceased. But on one evening a friend, who was in no sense a patient, was making a call upon him, and talked long, when Little was very tired. After a time, the doctor's mind wandered afar off from the discourse to the discussion of medical cases and questions, and, turning to his friend, who was in the full tide of talk, he asked with great gravity, "Please let me see your tongue." Little was never able to explain what happened when his friend had fairly taken in the meaning of this interruption.

But you will demand an end to this desultory contemplation of the varied sides of our late associate's life and character. A quarter of a century was to be the limit of his professional life. In the apparent ripeness not of old age, but of middle life, it was ordered that his work should end. As has already been intimated, he was actively engaged at a professional meeting up to a late hour on Tuesday, March 31st, and on Saturday, April 4, 1885, he was in the life beyond. In August, 1884, it was discovered that he was suffering from diabetes. I believe it is thought, by some authorities at least, that the debility induced by this disease, the existence of which was shown by the examination after death, made him less able to resist the acute affection from which he died. At any rate it had a sensible effect upon his apparent feelings and actions as observed by his intimates. His thirst was marked, and he became much fatigued upon slight exertion. But he continued his daily work, without creating a suspicion of the existence of any serious disease, in those who saw him only at intervals, until Wednesday morning, April 1st, when he called his friend Dr. Lloyd to his office, at about ten o'clock, and he found him with his head resting upon his hand, and complaining of a severe pain in the right iliac fossa.

He asked Dr. Lloyd to attend to his clinic for that day, while he proposed to make one or two calls in the after-

noon. He then went up-stairs and took a dose of cathartic medicine prescribed by himself. At noon he said he felt better, and he went out to try and finish some work, but he soon returned, complaining of severe pain. His family physician, Dr. John S. Campbell, was sent for in the evening; when Dr. Campbell arrived he ordered a dose of castor-oil, which he had seen relieve similar attacks in Dr. Little. The night passed without a movement of the bowels, and with a steady increase in the pain. Early in the morning he sent for Dr. Lloyd and gave him the necessary instructions in regard to his practice. When Dr. Campbell came for his morning visit he advised that Dr. Loomis be sent for in consultation, and when he came, although he thought there was beginning typhlitis, he advised a dose of calomel. He also had seen Dr. Little in similar attacks, which had been relieved by cathartics.

No alleviation of the pain was obtained, nor did the bowels respond to the frequent calls made upon them; and Friday, owing to the increase of the pain, it was found necessary to resort to the hypodermic injection of morphine. It was also noticed that there was a localized peritonitis, and when Dr. Campbell arrived, Dr. Sands was also called in consultation. By the time he arrived, in the afternoon, the inflammation of the peritoneum had become general, and it was a question whether it would be wise to operate. This was advised against, however, when the existence of the constitutional disease was fully considered. Although the hypodermic was used freely all Friday night, it was found on the morning of Saturday that the peritonitis was much aggravated. On this morning he sent for Dr. Lloyd, and when he got to the room he found him, in spite of the peritoneal inflammation, sitting in a chair by the side of the bed. As Dr. Lloyd entered the room he asked if he thought he looked much worse than the day before, and then immediately began to give instructions with regard to some business for the University of Vermont, which he thought ought to be attended to without delay. It was suggested to relieve the distention of the bowels by an aspiration, but he objected, and the matter was not urged. Dr. Lloyd, from whom I received these particulars, then continues: "After remaining with him for some time, I left to attend to the calls, and was probably absent about an hour. Upon my return I was met at the door by one of the servants, who asked me to hurry to the room, as the doctor was worse. Hurrying up-stairs, I found Drs. Campbell and Powell already there, and that collapse had set in a few minutes before. Just before my arrival the doctor had asked Dr. Campbell, 'Doctor, don't you think a little digitalis would be good for this failing heart of mine?' Dr. Sands was also sent for and arrived in a very few minutes; but there was nothing to be done, and we now knew that the end was nearing fast. As I entered the room the doctor held out his hand with the expression, 'Lloyd, I am going now;' and then, a minute later, again calling me by name, he said, 'I now realize the truth of what poor Beard said.'[1] During all this time he was suffering intensely, but his mind was entirely clear, and his spirit undaunted by the fast approach of death. He summoned the household servants and family about his bedside, and casting anxious glances at a clock that was in his chamber, he plainly showed that he was counting the moments that he still had to live. Having bid farewell to each one by name, and with the words, 'I die in the Christian faith' upon his lips, there was a final instant of distress, when this brave man yielded up his spirit to the God who gave it."[2]

ANTIPYRINE AND SWEET SPIRITS OF NITRE are incompatible, according to Dr. Eccles.—*N. Y. Medical Journal.*

---

[1] This refers to the words of the late George M. Beard, in which he expressed his regrets that he could not express the thoughts of a dying man.

[2] At the autopsy a perforation of the vermiform appendix was found, and also a hardened mass of fæces, which was the probable cause of the ulceration, and there were proofs in the condition of the liver and kidneys of the existence of diabetes.

URETHRAL IRRITATION IN THE MALE THE CAUSE OF CERTAIN NEUROSES, AND ALSO OF ACNE.[1]

BY LEGRAND N. DENSLOW, M.D.,

ST. PAUL, MINN.

ALTHOUGH of late years much has been written about urethral irritation and its relation to nervous disturbances, I am inclined to think that its importance is far from being appreciated as yet. This conviction is the only apology I have to offer for trespassing upon your time, by recounting a few cases that have come under my observation recently. Dr. Otis, at a meeting of the New York Dermatological Society a little over a year ago, read a very interesting paper on contractions of the meatus urinarius as a source of reflex irritation in the brain and spinal cord; his cases, together with mine, make such an interesting series that I shall briefly refer to them. The first was a case of contracted meatus in a physician, associated with mental depression so great as to render all his mental processes unreliable, and to make him feel as if he did not care to live. These symptoms were entirely relieved by simply stretching the meatus three or four millimetres. The patient would not accept division, and he was obliged to dilate at intervals, each dilatation being followed by prompt relief. Again, case of a physician who had been subject to attacks of profound mental depression, coming on without apparent cause. This trouble he bore until he was past forty years of age, when to it were added various reflex nervous difficulties—among these a feeling of wetness in the urethra, and a bearing down in the perineum. A sound was passed and gave immediate relief, which continued for several weeks. A year afterward the meatus was divided, with the effect of permanently removing his nervous trouble. The same writer speaks of two cases who were subject to daily epileptic attacks, in both of which there was entire relief after division of the meatus. In one case it was found necessary to cut several times before the tendency to recontraction was entirely overcome, and the symptoms permanently relieved. The most interesting case described in his paper, and illustrative of another class of cases in which the reflex irritation falls more particularly upon the spinal cord, occurred in a child, aged three. As an infant it was restless and fretful, had frequent erections and enuresis; at two and a half years it was still in bad general condition and suffered from bilious attacks. About this time it was circumcised, with relief, though the attacks continued at night. Although there was no evidence of spinal disease, there was marked difficulty in locomotion, the child stumbling in his walk, with the right foot turned in, and falling every few steps. The meatus was found to be contracted and was cut, the operation giving great relief; but the meatus having again contracted, it was found necessary to cut again. To avoid hypospadias this operation was very carefully performed and repeated ten times, until no further recontraction took place. These numerous operations were found necessary, as the symptoms would return with the slightest recontraction. The child was seen two years after the date of the last operation, and found to be fat and well. My first case is similar in some respects to this last one.

CASE I.—April 3, 1885. C—— had gonorrhœa twenty-two years ago, discharge lasting several months. During treatment a piece of nitrate of silver was accidentally dropped in the urethra and allowed to dissolve. Patient complains of sensation of weight in the perineum, and pain in the same region during emission. There are darting pains through thighs and down the legs, the feet feel heavy and numb, and occasionally it is only with great effort that he can walk steadily. There is almost constant occipital pain, and the patient has about made up his mind to give up a good position. Upon exam-

---

[1] Read at the Ninth Annual Meeting of the American Dermatological Association.

ination the normal urethra was found to be 34. There were strictures at 1 inch, No. 24, from 1⅜ to 2¼ inches from 22 to 24, this one being particularly dense and showing the result of the nitrate, and one at 4½ inches, No. 19. All were incised to 36, and during the course of the next six weeks all the disagreeable symptoms disappeared.

Case II.—May, 1883. O——, aged forty-two, married, of good habits, uses no liquor or tobacco, is in perfect health. Complains that he has been impotent for eight years, and that the condition came on gradually. Upon examination meatus measured 16 (normal 34), otherwise urethra normal and not sensitive; the meatus was incised to 35 and a cure effected within a week. This occurred two years ago, and I have heard recently from the gentleman, that at present there is very little probability that any further treatment will be necessary.

Case III.—June 15, 1885. G——. Gonorrhœa seven years ago, which lasted about one month. Before he was entirely well he had connection with dissolute women, several times every night, for two weeks; at the end of that time he fell down in a fit, bit his tongue, etc. These attacks have occurred every few days, sometimes every day, until the present time. He is a printer, and has frequently fallen from his stool while at work. Had last attack yesterday. Stream of urine very small. Upon examination, normal urethra 34, meatus 29; stricture at 2 and 3½ in., admitting 29,; 4½ in., 26; 5½ in., 7. Following the examination he had a severe epileptiform attack. For the next week the lower stricture was stretched every other day until 22 was reached. The patient then had a pleurisy, from which he has not sufficiently recovered to proceed with urethral treatment. He has not had an epileptic attack since the day mentioned.

Case IV.—February 12, 1885. S——, aged thirty, single; no venereal disease. Complains that during the last year his hair, both on head and body, has been falling rapidly. He has a very extensive hirsute growth over the entire body, and upon removing the underclothes they are found to be lined with hairs. The scalp and a small spot on chest are found to be the seat of a seborrhœa, for which appropriate remedies were applied. The skin over the entire body is, to all appearances, in a perfectly healthy state. Thinking that the trouble must be reflex, I examined the urethra and found the prostatic portion highly sensitive. From this time patient was seen every other day, and sound passed. March 1st, less hair falling. March 11th, continued improvement. March 15th, scarcely any hair falling. March 31st, hairs on body firm, none falling. Within a few days the patient has been heard from, and there has not been any return of the body trouble, although hairs still fall from head and chest. I am not aware that general alopecia was ever before treated through the urethra. The result followed the treatment so rapidly, and proved so radical, that there is no doubt in my mind that the cause in this case was discovered.

Case V.—S——, aged twenty-six. Has had a constant neuralgia of the right testicle for past eighteen months. Had gonorrhœa two years ago, which lasted three months. There are numerous acne pustules scattered over the face. The patient told me subsequently that he has never been free from them since he was twelve or fourteen years of age. Has been impotent for past six months. Upon examination (normal urethra 34) meatus 26. This was enlarged to full size, and the deep urethra treated with sound. Within a month the acne had disappeared and the neuralgia was very decidedly improved, and after three months' treatment the neuralgia was cured by the systematic use of the sound together with galvanism. This case is an interesting one from the fact of the acne disappearing so rapidly. No mention was made of the acne either by the patient or myself until about one month after treatment commenced, when the patient informed me that he had "always had pimples" until the present time, and asked if I thought the operation and treatment had anything to do with their disappearance. This patient has been seen by me within a few days, and there is no return of the acne, and but occasional slight pain in the testicle. Upon further examination of his urethra with bulbs, a stricture of large calibre was found, three and a half inches from the meatus, measuring 32. I have every reason to believe that the remnant of the neuralgia is due to this contraction.

Case VI.—June 20, 1885. W——, aged twenty-nine. Prominent member of the bar and hard student. Has been morbid more or less as long as he can remember. Within two or three years has become abnormally sensitive, and finds that his mental processes are becoming obscured, has great difficulty in fixing his attention, and it is only with effort that he can grasp the subject of his reading. Upon examination of the penis find that he has been circumcised; the meatus 24 (normal 30) and lips protruding; the entire urethra exquisitely sensitive. The meatus was incised and a full-sized sound passed regularly. At this date, August 20th, the urethra is not sensitive, and the patient declares that mentally he is another man, that he is no longer despondent, and that within a week he has passed through a trial that prior to the operation would have "about killed him." I can notice a great change in his nervous condition. This patient applied to me for an aggravated case of acne, situated over the entire back from shoulders to buttocks, of fourteen years' duration, which has entirely disappeared without other treatment.

Case VII.—October 11, 1884. A——, aged fifteen. Had comedo when six weeks old, which disappeared in a few weeks. Normal skin thick and greasy. At present the whole face, ears, neck, and shoulders are covered with acne to an extent worse than I ever saw before, several abscesses being two inches in diameter, and a greater part of the skin of the face being infiltrated with pus, serum, and sebaceous matter. Disease commenced two years ago. Locally I treated him by opening abscesses and applying hot water, and gave gr. vj. ergotine t.i.d. By December 13th the acne had all cleaned up, except a few pustules on the back of the neck. At this time the urethra was examined. Meatus contracted to 27 (normal 34) and prostatic urethra very sensitive. As operation was declined, sound No. 27 was passed frequently for about six weeks, when urethra was no longer sensitive. During this time ergot was discontinued, but improvement continued until but very few pustules appeared on the neck.

April 18th.—No treatment but hot water for past two months, and slight relapse on neck. Ergot given again, and in a month the eruption had all disappeared. A few days ago he presented himself, having neglected treatment for the past two months. There was a decided relapse, principally about the neck and angle of jaws. There are many points of interest about this case: first, the fact of the skin being predisposed to acne, as shown by comedo appearing at the age of six weeks; second, the rapidity with which the disease disappeared under the use of ergot; third, the fact of improvement continuing when sounds were substituted for ergot; fourth, relapse occurring upon discontinuing either sounds or ergot. As the deep urethra is no longer sensitive it would be fair to presume that the acne is kept up by the contracted meatus, as it improves always after passing a sound. I regret my inability as yet to prove this.

Case VIII.—June 22, 1885. W——, aged thirty-one. Has suffered from acne for years. At present back is pretty well covered from shoulders to lumbar region. Urethra 30; meatus normal. Strictures Nos. 26 and 28 at one and two inches, the entire urethra very sensitive, and particularly so in the deeper portion. Treatment: Sounds passed every other day.

July 7th.—Acne has disappeared. At this time patient was ill and obliged to stay at home for two weeks,

and at the end of that time a few more pustules had appeared. At the present time there is no acne.

I simply present these as an interesting group of cases. I have no theory to offer, but would call particular attention to the case of general alopecia cured, and also the result in the cases of acne, adding, as they do, evidence as to the efficacy of Dr. Sherwell's treatment by sounds, suggested by him at the last meeting of this Association.

A CASE OF GUMMA OF THE CONJUNCTIVA.

By LE ROY POPE WALKER, M.D.,

LATE HOUSE SURGEON NEW YORK EYE AND EAR INFIRMARY, MEMBER AMERICAN OPHTHALMOLOGICAL SOCIETY, FELLOW NEW YORK ACADEMY OF MEDICINE, ETC.

E. L——, sailor, aged twenty-five, was admitted to the New York Eye and Ear Infirmary (service Dr. W. F. Mittendorf), September 17, 1885, with a well-developed gumma of conjunctiva and a circumscribed scleritis of three weeks' duration, left eye.

He gave a clear history of infection, one year ago, which had been treated in a desultory manner at Constantinople, Turkey, and again, in London, England.

The gumma was located at the sclero-corneal margin, upper and outer quadrant, with a base 3½ mm. in diameter, and an elevation of 1½ mm. There was mild ciliary injection. Cornea and aqueous humor perfectly clear; no signs of iritis. Iris dilating and maximum readily. He also had a mild form of scleritis, limited to inferior segment; no swelling or bulging. His general health was excellent, presenting no other evidence of syphilis.

Began immediately with inunctions of mercury, together with pot. iodide, grs. x., and instillations of atropia, grs. ij. to ʒ j., three times a day. He was also given a collyrium of boric acid morning and evening.

Third day, slight ptyalism. Inunctions discontinued. Pot. iodide, atropia, and boric acid as before, and, in addition, a gargle of pot. chlorate ordered every hour. Gumma much diminished, and circumcorneal injection fast disappearing, as also scleral congestion. He experiences now no inconvenience from movements of lids over gumma, of which he previously complained.

Seventh day, salivation entirely relieved, ciliary injection rapidly fading, and gumma reduced two-thirds. Pot. iod., atropia, and boric acid continued.

Fourteenth day, gumma has entirely disappeared, with only a *very faint* injection of scleral vessels in region of recent scleritis. Same treatment continued.

Discharged on the twentieth day, cured, only one or two small scleral veins showing, as evidence of former trouble. This case is reported mainly to demonstrate the efficacy of rapid mercurialization in syphilitic affections of the eye, and also to show their tractability when energetically treated.

NITRITE OF SODIUM IN GOUT EPILEPSY.—Dr. J. Mortimer Granville writes to the *British Medical Journal*: "I am obtaining highly satisfactory results in epilepsy associated with gout with the following formula: ℞. Sodii nitritis, gr. xxxvi.; sodii hippuratis, ʒ iij.; infusi serpentariæ, ad ℥ xii. Misce. Two tablespoonfuls are to be taken three times a day before meals. The dose of the nitrite of sodium may be increased by one grain after each fit which occurs subsequently to the commencement of the treatment. The mixture should be used regularly for about three or four months; the dose of the sodium nitrite being increased, as I have suggested, until it reaches fifteen grains. In a number of cases recently treated in this way, the fits have ceased before the progressive augmentation of the nitrite raised the dose to ten grains. I am very confident that the profession will find the combination worthy of a trial. If there be constipation or a jaundiced appearance at any time during the treatment, I give the following pill several successive nights until the condition is improved: ℞. Iridin., gr. ij.; extracti cascaræ sagradæ, gr. iij. Misce. Ft. pil."

Clinical Department.

A REMARKABLE CASE OF ASCITES.

DR. WILLIAM A. MCDONALD, of Lynn, Mass., reports the case of a woman, about fifty years of age, who came under his care in December, 1880, suffering from an accumulation of fluid in the peritoneal cavity. She stated that the abdomen had been tapped six weeks before, while she was living in the West. Dr. McDonald introduced the aspirator needle and drew off twenty-two quarts of fluid, and from that time until the present the operation has been repeated at intervals of about two weeks, from sixteen to twenty quarts being removed each time. Examination of the urine failed to reveal any cause for the ascites, and neither the liver nor the heart presented any symptoms of disease. Medicinal treatment was ineffectual in preventing the exudation or in promoting its absorption. The patient has now furnished about five hundred gallons of fluid, but seems to have suffered in no way from this abnormal excretion, her general condition presenting no change save that incidental to increasing years.

THE CHLOROFORM TREATMENT OF TAPE-WORM.

DR. L. E. BORCHEIM, of Atlanta, Ga., writes: "Having been one of the opponents of the method of treating tape-worms to a dose of chloroform, I think it my duty to record the result of a more extensive experience with this remedy. I have employed it in six cases since the publication of my last letter, and in all with success, and without any unpleasant effects worth mentioning. The promptness of the action of the drug is such that I think it should receive the preference over others, at least for the first attempt. Should it fail (and what remedy is there that will not sometimes fail?) the inconvenience suffered by the patient is so slight that he will not hesitate to repeat the dose should it be deemed advisable. My plan is to order an early and light supper, and then instruct the patient to take before breakfast, the following morning, one drachm of chloroform, with from one-half to two minims of croton-oil. A prompt action is insured by the croton-oil, and to it, I believe, is due in great measure the success of this mode of treatment." [The writer is, we fear, a little too positive in his assertion of the harmlessness of chloroform. Cases have been reported in these columns, and elsewhere, in which alarming symptoms have followed the exhibition internally of this drug, and we should not be surprised to learn that its use in this manner had even been attended by fatal consequences.—ED.]

POISONING BY CHLORATE OF POTASSIUM.

DR. SIMMONS B. JONES, of Charlotte, N. C., reports the following interesting case: A little girl, nine years of age, had been under his care for a slight fever, with weak pulse, nausea, and continual vomiting, but, having apparently recovered, was dismissed as cured. On the day following, July 26th, the child had a sore mouth, and her mother gave her a paper containing something over an ounce of chlorate of potassium, allowing her to take it *ad libitum*. The girl liked the taste, and ate the crystals all day, consuming in this way between two and three hundred grains. At about two o'clock on the morning of the 27th the patient awoke vomiting. When seen some five hours later she was deathly pale, with blue lips, and a very rapid and feeble pulse, and presented exactly the appearance of one who had had a sudden and copious hemorrhage. "I had no idea at this time of the cause of the trouble, the parents having said nothing about the chlorate of potassium, believing it to be a harmless drug; but I suspected poisoning. The patient

remained in this condition the three following days, vomiting and being unable to retain any food, and passing no urine. On the fourth day I introduced a catheter and drew off about five ounces of smoky urine, which, on examination, was found to contain albumen, casts, and altered blood. Dr. H. Formad, of the University of Pennsylvania, who examined a specimen, reported: 'I fully coincide with you about the urine; it contains a very large quantity of granular blood, epithelial casts, and free blood, showing a profound renal affection.' The urine was drawn for several days, and then began to be passed naturally in sufficient quantity, the blood disappeared, and the water resumed its normal color. An analysis, by Dr. Hannah, of eight ounces drawn the second day, showed six grains of potassium chlorate. The vomiting continued until August 14th, the matter vomited consisting of dark green mucus of an offensive odor. On August 16th there was seen an eruption of small maculæ of a purple color, upon the forearms. The temperature rose to 100° on the 20th, the submaxillary glands became swollen, the throat was red and œdematous; the patient sank gradually, and died on August 26th. She never complained of much pain, and there was no tenderness over the stomach. The bowels were at first constipated, but when action was solicited the matter passed was dark and resembled the urine in appearance. There was complete anorexia throughout the entire period. Life was sustained by enemata of beef, peptonoids, and milk until the rectum became too irritable to retain the injections. After the vomiting had ceased, the patient was able to retain a little buttermilk. During the first few days much relief was obtained by warm baths, which were always followed by profuse perspiration and quiet sleep." No autopsy could be obtained.

TREATMENT OF A REBELLIOUS CORN.

Dr. R. C. Newton, Assistant Surgeon, U.S.A., writes from Fort Elliott, Texas, concerning a soldier, thirty-three years of age, who was suffering from a large callosity, caused by a splinter which he had run into the sole of his foot two years ago. The callosity resembled an ordinary corn, but was as large around as a quarter of a dollar, and gave but little pain except when the man walked about. The corn was vigorously treated by excision, poulticing, scraping, salicylic acid, cannabis indica, collodium, etc., but without avail, for each time that it was removed it grew again with most commendable persistency. Anti-syphilitic treatment was also tried without success. Finally Dr. Newton had resort to liquor potassæ, as recommended by Erichsen for callosities, and, after making applications twice a day with this substance for a period of four months, was rewarded by seeing his patient cured and returned to duty.

THE BAROMETER AS A GUIDE TO HEALTH.

Dr. M. A. Veeder, of Lyons, N. Y., has been led by his observations to believe that the barometer may become an instrument of as great value in saving life as it is now in saving crops or ships. It is a familiar fact, he says, that many persons who are afflicted with rheumatism are able to foretell changes of the weather by means of the aches and pains that they experience. Persons who are subject to headache, also, are apt to suffer most when the mercury in the barometer is changing its level rapidly, as, for instance, before a thunder-storm. The cause of these symptoms appears to be a difficulty in the adjustment of the volume and rate of the circulation of the blood to the varying atmospheric pressure upon the surface of the body. Ordinarily the results are not serious, and but little attention is given to the subject. The question arises, however, as to whether there may not be a class of cases in which the movements of the mercury in the tube may become of great prognostic import. Dr. Veeder says that he has noted the occurrence of several deaths from apoplexy at times when rapid fluctuations of atmospheric pressure were indicated by the barometer; and he believes that at such times over-excitement, over-eating, improper clothing, and the like, may induce consequences most disastrous to those who are predisposed to apoplexy, the weakened blood-vessels being already subjected to unusual strain by reason of the unfavorable atmospheric conditions. Although the cases observed by the writer thus far are not numerous, yet he maintains that the probabilities with regard to the matter are such that it is the part of wisdom that those who are advanced in years, or subject to symptoms that indicate an apoplectic tendency, should be warned to exercise great moderation in all things, whenever the mercury is seen to be unusually active in its movements.

A CASE OF INTRA-UTERINE SUPPURATION.

Dr. Hamilton Vreeland, House Physician and Surgeon in the Jersey City Hospital, reports the following interesting case: Mrs. J——, primipara, twenty-four years old, was admitted to the lying-in ward, with a history of being fully nine months pregnant and of having enjoyed good health during that entire period. Examination of the urine at three different times showed a specific gravity of 1.024, no albumen and no casts. The patient remained in the hospital ten days, doing light work about the ward, and being apparently in excellent health. On the eleventh day she kept her bed, complaining of pains in the back, and during the day vomited a small quantity of greenish material, but ate the usual quantity of food. In the evening labor began, the membranes ruptured, discharging a small quantity of liquor amnii, and the head descended into the pelvis. At about midnight the patient began to complain of thirst, the skin was dry, pulse 110, and the pains grew weaker until nine o'clock the following morning, when they ceased. At this time the occiput was under the pubis, but the woman was cyanotic, and the pulse was 120 and feeble. The head was now delivered with the forceps, and this was followed by a gush of sanguineous pus and mucus of a most disgusting odor. Ergot and stimulants were administered, but no uterine contractions followed, and the delivery was completed by traction upon the chin and occiput. The fœtus was large and fully developed, and had apparently been dead about two weeks. Its extraction was followed by another discharge of pus. The placenta was firmly adherent and was removed by the hand introduced into the uterus. There was no hemorrhage, but the patient remained cyanosed, with feeble and rapid pulse and cold extremities, and sank rapidly until death supervened. At the autopsy, made twenty hours after death, the right heart was found to contain a white clot filling both auricle and ventricle. The abdominal cavity contained a pint of dark brown fluid, but no pus and no fibrinous exudation. The stomach and intestines were congested, and markedly distended with gas. The uterus was the size of a large cocoanut and was the seat of three small fibroids. The walls were thin and succulent on the inner surface, exuding pus when squeezed, and the cavity contained purulent matter and blood-clots. There was no pelvic abscess nor sign of inflammation around the uterus or vagina. The woman had denied receiving any injury, but the husband stated that, two weeks before entering the hospital, she had, in a fit of frenzy, pounded her abdomen, exclaiming that she would kill the child. There were, however, no signs of any bruises, and the woman presented no untoward symptoms prior to the day on which labor began

‖ Dundakine.—This is a bitter resinoid substance, soluble in water and alcohol, obtained from the bark of the *sarcocephalus esculenta*, growing in Senegal. According to Haeckel, it possesses astringent and antipyretic properties, and has been proposed as a substitute for quinine.

Progress of Medical Science.

THE ETIOLOGY OF CHRONIC NEPHRITIS.—At the last meeting of the French Association for the Advancement of Science, M. Lépine delivered the following opinions on the etiology of Bright's disease. The cases may be arranged into two classes, the first of which is dependent on a habitual dyscrasia, using this word in its widest sense—*i.e.*, any modification in the constitution of the blood. The second class consists of "ascending nephritis," among which may be reckoned microbic pyelonephritis, arising independently of any previous alteration in the urinary passages, and the real occurrence of which is said to have been proved by the experiments of Lépine and Roux. The relatively tardy elimination of iodine by the urine after its subcutaneous injection is given as a sign of chronic nephritis.

ELEVATION OF THE ARMS AS AN INDICATION OF PERITONITIS.—Dr. Lediard, in *The Lancet* of September 19, 1885, refers to this subject. He calls to mind that there are various circumstances rendering the attitudes assumed by the sick of great diagnostic value. It may be that extreme restlessness, delirium, or fear, may prevent accurate noting of the pulse, temperature, respiration, or even physical examination of diseased organs. Again, deaf-mutism, malingering, a foreign language, etc., may further entail difficulties in diagnosis which might be in some measure overcome by the observance of a well-established position pathognomonic of a disease. He then alludes to one disease and one posture, which seem to be rarely dissociated, at least in the adult. Many years have passed since he was first struck with a posture which he has generally found to be a truthful indication. On November 19, 1871, a waiter, aged twenty-two, was brought into the Edinburgh Infirmary, under the care of the late Professor Spence, whose house-surgeon he then was. The patient had been stabbed in the abdomen, and a foot of small intestine was protruding. On the day following admission the patient was noticed to keep his hands above his head with the elbows out—*i.e.*, in a position often assumed when one is lying on the grass in summer enjoying the sounds of nature. Subsequently, but within twenty-four hours, he was observed to raise the left thigh; finally, the hands were constantly behind the head and the knees completely drawn up. Death occurred on the fourth day from general peritonitis. In peritonitis following the operations for hernia, gastrotomy, ovariotomy, ruptures of the bowels following violence without external mark, and in puerperal peritonitis, the author has constantly observed the position taken by the patient to be similar to that described. The raising of the arms is, in his belief, coincident with the commencement of peritonitis, and when the inflammation is at its height the hands will be clasped behind the occiput. The explanation is simple enough; the object being to lift all pressure from the distended bowels, the respiration becomes thoracic and the diaphragm fixed; by raising the arms the pectoral muscles elevate the ribs, and more room is thereby allowed for lung expansion; the raising of the arms moves the scapula upward and forward, and the serratus magnus being drawn upon still further tends to relieve the thorax from pressure, while the dorsal position of the trunk with an extended spine favors respiratory movement.

GENERAL CARCINOSIS—APPARENT RECOVERY.—Dr. Brunon relates in the *Gazette des Hôpitaux*, No. 61, 1885, the case of a woman, thirty-two years of age, who had suffered for eighteen months from a rapidly growing tumor of the left breast. After having existed for ten months the tumor ulcerated and then cicatrized, being somewhat smaller than before. Two months later the right breast became similarly affected, and the patient entered the Hôtel Dieu. She was then markedly cachectic and seemed to be rapidly nearing death. In the left mamma was a hard tumor, the size of an egg, firmly adherent to the surrounding tissues, with hard cords radiating in all directions beneath the integument. In the right mamma was a tumor of similar appearance but not so far advanced. The supraclavicular and axillary glands of the left side were enlarged and indurated, and the left arm was œdematous. The liver was enlarged, and there were numerous hard, movable nodules, the size of a hazelnut, in the skin of the abdomen, chest, and neck. There was also an effusion into the pleural and peritoneal cavities. The author regarded the case as one of general carcinosis, originating in a scirrhus of the breast, and looked upon it as hopeless. But on general principles he ordered nutritious food and syrup of the iodide of iron with arseniate of sodium. Under this treatment the patient began to improve in general health, the swollen glands grew smaller, the œdema of the arm disappeared, the tumor of the left breast decreased steadily in size, and the nodules of skin disappeared entirely. The author maintains the correctness of his diagnosis, and says that syphilis was certainly to be excluded. In referring to this case a writer in the *Centralblatt für Chirurgie*, No. 37, 1885, relates a very similar one reported by Dr. Gluck at a meeting of the Berlin Medical Society. In this case a typical carcinoma had been removed from the breast by von Langenbeck four years previously. Two years later there was a return of the disease in the cicatrix, in the form of "cancer en cuirasse," which increased, despite arsenic injections, and finally converted the entire breast into a suppurating mass. There were also some seventy or eighty tumors, from the size of a pea to that of a hazelnut, in the surrounding skin. There was œdema over the thorax and on the arm, the knee was the seat of an exudation, and the chest contained a bloody fluid. Under injections of arsenic and morphine, and treatment of the suppurating breast with iodoform and sublimate, the abscess healed, the articular exudation was reabsorbed, and the cutaneous nodules disappeared. And at the time the report was made it was stated that the disease had been so far recovered from that "no surgeon would now advise the removal of the breast."

RESORCINE IN GONORRHŒA.—Dr. A. J. Munnich has treated a number of cases of gonorrhœa in the following manner: The patients are instructed to drink as much water or milk as possible, so as to be able to pass water and wash the pus from the urethra before each injection. Then, every two hours during the day, and at least twice during the night, an injection is made of a syringeful of a three per cent. solution of resorcine, the fluid being allowed to flow away immediately. On the fourth or fifth day the secretion will be much reduced, and it will be necessary to practise the injections but three or four times during the day and once at night. Treatment should be continued for about a fortnight. Dr. Letzel has also used resorcine with success in upward of fifty cases. In some the treatment had to be discontinued by reason of the irritation to the urethra caused by the drug, but in about eighty-five per cent. the result was most satisfactory. It is necessary, however, to take great care as to the quality of the drug used. Chemically pure resorcine is snow-white, and forms a perfectly clear solution in distilled water.—*Deutsche Medicinal-Zeitung*, September 10, 1885.

URETHAN, A NEW HYPNOTIC.—This substance ($NH_2CO_2C_2H_5$), which was first employed by Schmiedelberg in experiments on animals, occurs in the form of white, odorless crystals, readily soluble in water, and has a not unpleasant taste suggestive of saltpetre. Von Jaksch (*Deutsche Medicinal-Zeitung*, September 14, 1885) has given the drug to man in upward of one hundred cases, in doses of about fifteen grains. He found that its action was exerted chiefly upon the brain, having no appreciable influence over the peripheral nerves. It seems, therefore, to be a pure hypnotic, having no influence in arresting cough or in quieting neuralgia, or the lancinat-

ing pains of locomotor ataxia. The writer states that it is very well borne, has no unpleasant secondary effects, and causes a quiet and seemingly normal sleep. He recommends its use, especially for children and in delirium tremens and mania. It may be given in simple aqueous solution.

Cherry-laurel Water as a Local Anæsthetic.—Dr. Fodor has successfully employed urethral injections of cherry-laurel water for the production of local anæsthesia prior to catheterization. It is injected ten minutes before the introduction of the catheter, and allowed to remain up to the moment of the operation. The author recalls the fact that oculists formerly used cherry-laurel water, or dilute hydrocyanic acid, as an eye-wash in painful affections.—*Deutsche Medicinal-Zeitung*, No. 73, 1885.

Fatal Sublimate Poisoning.—Dr. H. Keller relates the case of a woman, fifty-two years of age, from whom the uterus was removed through the vagina on account of carcinoma. During the operation the wound was thoroughly irrigated with a 1 to 4,000 sublimate solution. The next day two vaginal injections, of about a quart each of the same solution, were made. The following morning there was diarrhœa with tenesmus, and in the evening the patient had bloody stools, with a small pulse of 156 to the minute, great thirst and restlessness. She passed about ten ounces of bloody urine containing hyaline, granular and epithelial casts, and renal epithelium. The day following this the patient died. The writer thinks that corrosive sublimate should not be used as a disinfectant in cachectic and anæmic individuals, or in those suffering from renal disease.—*Centralblatt für Gynäkologie*, No. 32, 1885.

Conception after Scraping of the Uterine Cavity.—B. Schultze warns against the use of the curette in women not past the child-bearing period, believing that thereby conception is rendered difficult, if not impossible. But Düvelius has collected sixty cases in which conception followed the scraping of the uterine mucous membrane, and Benicke has reported ten of the same nature. In three of the latter group the curette was employed twice. In these ten cases there were thirteen conceptions within sixteen months—five abortions, and eight pregnancies going to full term. In two cases conception followed within five weeks after the operation.—*Wiener Medizinische Wochenschrift*, September 5, 1885.

Sugar in the Blood of Carcinomatous Patients.—After the publication of Freund's statement that he had found sugar in the blood of seventy patients with carcinoma, and none in the blood of thirty individuals who were also ill, but had not cancer, Mátrai undertook some investigations in the same direction. He found sugar in the blood of eight patients with cancer, out of eleven examined, and also in four out of an equal number of non-cancerous invalids. These four were all markedly cachectic, and it is to this condition that Mátrai refers the presence of sugar. Claude Bernard's experiments showed that, if a dog were bled, the last part of the blood which flowed away contained sugar. But in cachexia the blood is reduced in quantity, and it is to this cause that the presence of sugar is to be attributed.—*Deutsche Medicinal-Zeitung*, September 14, 1885.

Nerve-stretching.—In a thesis with this title, published in the *Gazzetta Medica di Roma*, Nos. 18 and 19, 1885, Dr. Vincenzo Morini concludes that the procedure may be employed in all forms of neuralgia, especially of rheumatic or traumatic origin, when the usual remedies have proved ineffectual, and when the pain is known not to proceed from the irritation of a tumor, cicatrix, or the like. In case of the sciatic nerve it is practicable to first attempt stretching by flexing the thigh, with knee extended before resorting to an operation. Nerve-stretching is also indicated in ascending neuritis, reflex epilepsy, and muscular contracture or spasm of peripheral origin, especially when traumatic. It is generally contra-indicated in secondary facial neuralgia, and in such cases, instead of promoting a cure, may even cause a more or less prolonged paralysis. In traumatic tetanus this procedure is not specially contra-indicated, and may indeed be tried with advantage if the source of irritation be well determined, and if all the principal nerve-trunks supplying the part be stretched. It is of no avail in any form of central disease, though, when the sciatic is the seat of pain, some amelioration of this symptom may possibly be obtained by resorting to stretching without operation. In other neuroses it is better to abstain from any attempts at nerve-stretching, at least until it has been more clearly determined what conditions are benefited by this procedure and what are not.

Subdiaphragmatic Abscess with the Physical Signs of Pleurisy.—Dr. E. Waahlen relates in the *Upsala Läkareförenings Förhandlingar*, vol. xix., 1885, the case of a woman, thirty-eight years of age, who suffered from acute general peritonitis. On the first examination the lungs were normal, but two weeks later dulness on percussion and absence of respiratory sounds were noted from the third intercostal space anteriorly, and from the spine of the scapula posteriorly, to the base of the lung. At the border of this area of flatness there was bronchial breathing, and, higher up, vesicular respiration. The patient was so weak that nothing could be learned from the vocal fremitus, and a few days later she died. At the autopsy there was found diffuse suppurative peritonitis, but in addition there was an encapsulated abscess between the upper surface of the liver and the diaphragm. The latter was pushed up anteriorly as high as the third rib, and the lower lobe of the right lung was consolidated. The abscess contained nearly two pints of pus. The author remarks that, even had the purulent collection been tapped, it would still have been supposed to be an interpleural exudation, and in any event the correct diagnosis could be made only at the autopsy.

Simulated Hæmoptysis and Hæmatemesis.—Dr. S. Wallgren relates the case of a young girl, who was anæmic and complained of a cough and various pains, who pretended to have hemorrhages from the lungs and stomach. The alleged attacks always occurred at night, and it was found that the girl obtained the blood necessary for her deception by means of leeches.—*Upsala Läkareförenings Förhandlingar*.

Treatment of Gouty Joints.—To shorten an attack of acute gout, Dr. Rothe recommends repeated cold douches followed by an application of the following solution: Liquor plumbi acetat., 15 parts; spiritus vini, 25 parts; tr. opii ammoniat., 5 parts; aquæ font., 300 parts. Compresses wet with the solution are to be applied to the affected joint and covered with rubber tissue. The writer has seen great relief of pain follow this treatment in other patients as well as in his own person.—*Memorabilien*, No. 4, 1885.

Reproduction of the Testicle.—Professor Luigi Griffini has been conducting a long series of experiments upon frogs to determine the question of the reproduction of the testicles after wounds and injuries to these organs. The following are his conclusions: 1. A partial reproduction of the testicle occurs in the frog. 2. The newly formed parenchyma is derived from that pre-existing. 3. The cells of the stroma do not take any part in the formation of new glandular tissue.—*Gazzetta degli Ospitali*, No. 68, 1885.

Ulcerations of the Digestive Tract Caused by Morphine.—Dr. Amadeo Sourrouille relates the case of a woman, suffering from cancer of the uterus, who could find no relief from her pain except by the use of morphine. She shrank from hypodermic injections and therefore took

the drug in pill form. The dose was gradually increased from three-fourths grain up to four grains. The pain was quieted, but the patient suffered from the usual effects of morphine upon the digestive and urinary tracts. Soon after, numerous ulcers, some superficial and others deep, were seen upon the mucous membrane of the mouth and pharynx. Suspecting that the morphine might be the cause of this trouble the author advised its discontinuance, and in a short time the ulcerations disappeared. A few weeks later the pain became so severe that it was necessary to resort again to the morphine, and almost immediately the ulcers reappeared in the mouth.—*El Sentido Católico en las Ciencias Médicas*, No. 32, 1885.

Therapeutic Uses of Capsicum.—In an article on this subject in *La Crónica Médica de Lima*, No. 19, 1885, Dr. M. Ceballos Torses relates a number of cases of different affections in which the employment of red pepper was followed by excellent results. He found benefit from its use in chronic dysentery and hemorrhoids and in vomiting, especially in the vomiting of pregnancy. It was also given with happy effect in several cases of bilious fever peculiar to warm climates, the symptoms of which bear so close a resemblance to those of yellow fever.

Joint Affection Complicating Conjunctivitis Neonatorum.—Dr. Johan Widmark relates in *Hygiea*, No. 8, 1885, the case of an infant suffering from conjunctivitis, acquired probably from another baby lying in the same apartment. The disease was not very severe, but was rather obstinate in its persistence, and the secretion contained gonococci. On the sixteenth day of the disease the mother noticed that the infant did not move the right leg, and that the ankle on this side was swollen, red, and tender on pressure. The joint affection yielded readily to treatment and had entirely disappeared at the end of two weeks. Cases similar to this are very rarely reported, but if conjunctivitis neonatorum is a gonorrhœal affection, the occurrence of joint implication should not be very rare.

Case of Gastrotomy with Canule à Demeure.—Professor Sklifasowsky (*Revue de Médecine*, No. 2, 1885) performed gastrotomy on a woman, fifty-nine years of age, who had a stricture of the œsophagus, due to cancer. The patient died six months after the operation from generalization of the cancer. The case is described especially to show the employment of a permanent canula, which the operator adopted for the case. It was quite similar to the double canula commonly used in tracheotomy. The advantage of such a canula is that it can be left constantly in place. If desirable, it may be sealed hermetically. In the observation reported it was very well borne, and remained in place two or three weeks at a time without its removal being necessary. To feed the patient, the end of a stomach-pump tube was inserted into the canula and the nourishment introduced, after being subjected to the mastication and insalivation of the patient herself, who thus was permitted to enjoy the sense of taste.

Parthenine as a Febrifuge.—Dr. Tovar, a Cuban, has experimented with the parthenium hysterophorus, a plant which is much used by the country people of Cuba in the form of an infusion as a febrifuge. Physicians, as well, in the central districts of the island have employed it to advantage as an antiperiodic. Among the substances which the plant contains is parthenine. This appears in dark-colored scales, which color water yellow and give to it an aromatic taste. This substance the writer administered to eighty patients, in whom quinine was indicated. It produced a rapid diminution of the fever. The maximum dose was thirty grains.—*Cronica medico-quirurjica de la Habana.*

Osteitis of the Coracoid Process.—Professor Poncet, of Lyons, read a paper on this subject before the French Association for the Advancement of Science at its last session in Grenoble. The disease, he says, occurs with greatest frequency in the period of adolescence, before the consolidation of the epiphyses, and is liable to be confounded with scapulalgia, osteitis of the head of the humerus, or even conical Pott's disease. The diagnosis may be made by the location of pain on pressure, and by the presence of tumefaction or of an abscess. The latter is found usually in the subclavicular region rather than in the scapuli-humeral, or on the internal aspect of the arm, the pus following the sheath of the coraco-brachial muscle, or of the short head of the biceps. The treatment consists in resection of the process by means of a T-shaped incision. In the case of tubercular osteitis, union by first intention cannot be hoped for, and it will be necessary to provide for free drainage.—*Bulletin Général de Thérapeutique*, September 15, 1885.

Pernicious Lymphodermia.—By this name Kaposi designates a new form of skin disease of which he has seen but one case. The patient, a woman, thirty-nine years old, had suffered for over a year from an affection of the skin, accompanied by itching and degeneration, which presented all the appearances of a chronic eczema. The skin was very pale, suggesting leucæmia, and there was a diffuse, doughy œdema of the subcutaneous connective-tissue, with thickening of the corium and epidermis of the face, neck, and superior thoracic region. Within a few weeks after the patient's admission to hospital several large nodules made their appearance in the subcutaneous tissue and corium. In the former region they were presented as localized infiltrations without well-defined outlines, but in the cutis they resembled ordinary eczematous furuncles. They were seen on the arms, face, breast, and clavicular region. Some of them opened spontaneously, discharging a creamy substance, and then cicatrized or became converted into flat ulcers. Fresh nodules appeared, the old ones increased in size, the spleen became greatly enlarged, the œdema spread gradually over the entire body, although the examination of the urine gave negative results, and the blood presented evidences of steadily progressive leucæmia, until finally, five months after admission to hospital, the woman died suddenly. At the autopsy lymphatic nodules were found in the lungs, as well as in the skin and subcutaneous tissues. The lymphatic glands were converted into fatty tumors, the spleen was four times the natural size, and its pulp was of a homogeneous pale-red color. The marrow of the small bones and of the extremities of the long bones was of a grayish color, but in the shafts of the bones it was very dark red.—*Centralblatt für Chirurgie*, September 12, 1885.

Properties of the Quillaya Bark.—The two glucosides which exist in Senega root and give to it its medicinal properties, are found, it appears, five times more abundant in the quillaya bark. This fact induced Dr. Kobert, of Strassburg, to substitute the latter bark for Senega in the treatment of diseases of the respiratory organs. Its action as an expectorant appears well established, and its administration provokes neither diarrhœa nor vomiting, and is much preferred by the patient. Children take it readily, on account of the sweetish taste of the decoction, which differs materially from that of Senega. Dr. Kobert advises its administration in decoction, made with five grammes of the bark to two hundred grammes of water. The dose for an adult is a dessert-spoonful every hour, and for a child a teaspoonful.—*Centralblatt für klin. Medicine.*

Treatment of Pulmonary Gangrene by Inhalations of Carbolic Acid.—M. Paul has employed this method in seven cases, in all of which a rapid and permanent cure was obtained without the appearance of any toxic symptoms. The solution employed was of the strength of one part in seven of water, and was enclosed in a flask, the patient inhaling the vapor. In addition to this, eucalyptus was employed internally in doses of one-half drachm of the alcoholate per diem.—*Bulletin Général de Thérapeutique*, September 15, 1885.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, November 7, 1885.

THE PAY-PATIENT ABUSE.

PRACTICE always falls below theory in the working out of social problems. The pay-patient system existing in our hospitals is an illustration of this fact. We hear a great deal at the present time about the physician's duty to the community. Is it not time that we heard less about this and more about the community's duty toward the physician. It is a poor system of every-day ethics in which all the obligations are on one side and all the rewards on the other. If the physician and the community could be weighed against each other in the scale of ethical relations, which party, think you, would be found wanting. The physician is in every respect ready to sacrifice his time and talents for the public good. Is the public disposed to make on its part an equal sacrifice. Notoriously it is not. The entries under the head of "bills payable" in the ledger of any medical man speak more forcibly than can any words of ours. The men who minister to mere creature comforts—the grocer and the butcher—must be paid. Those who care for bodily ills, and by their skill replace disease with health can wait for their pay. A contemporary truly says, "The patient's gratitude to his doctor is part of his disease. It is most declared when the fever is highest, cools off during convalescence, and entirely disappears with the complete return of health." During the past few years the public here in New York seem to have been looking about for some new burden to lay upon the shoulders of the medical profession. They have found one in the pay-patient systems of our hospital wards, and more particularly private rooms.

This system is faulty not so much in itself as in the method of its application. A person of means who is living at a hotel or boarding-house is stricken with some serious illness. Careful attention is necessary. Supposing he is away from home, there is no one who cares particularly about him or for whom he particularly cares. The expense for attendance, nurses, medicines, etc., will amount to a considerable sum. Or again, his case may be of such a nature that he cannot well be cared for in a hotel or private house. Under these circumstances he bethinks himself of some reputable hospital whither he may go and be well looked after. This is right, we think, in every respect. He is acting in self-defence. He is honorably following the old rule of looking out for number one. Against such cases we do not inveigh. The hospital is the proper place for them.

But there are many who go to the hospital from no such motive. They may be taken sick in their own homes, but they choose to go to a hospital private room—not so much, perhaps, from motives of economy, as because they can be cared for with less trouble than at home. Even this would be no violation of social ethics, were the physicians at the hospital, attending and resident, allowed to receive any compensation for services rendered. They are debarred from any such compensation. The hospitals purport to be and glory in being places where the best of treatment is given free of charge; and then they go through the somewhat ostrich-like proceeding of making out bills to private patients for "board," as they are "not allowed to make any charge for medical attendance." Again, persons are received at the hospitals afflicted with chronic diseases, who are peevish and fretful, whose wails about indefinite aches and pains would exhaust the patience of a Job, who make life a burden to all with whom they are brought in contact. Their own families have finally become tired out with them. Instead of sending them to some sanatorium, where they would be vastly benefitted, they take them to a hospital. They know that the latter's regard for its own reputation will insure good care. The burden is shifted from their own shoulders to those of the hospital physicians. Is this an exaggerated picture? Let any one who has served in our large endowed institutions answer. Such patients often consider the necessary discipline of institutions irksome and overbearing. They forget that such discipline is at the bottom of the successful management of an aggregation of sick people.

These people are allowed to come into our hospital private rooms. For all the additional work imposed upon resident and attendant physicians the latter do not receive one cent. Nay, more, they are not allowed to. The fees which the patient would otherwise pay, are directed into the hospital treasury for "board," and the family physician is the loser. In a high moral sense such conduct is clearly an evasion of social obligations. Thus far we have spoken only of medical cases. Similar flagrancies are observed in the cases of surgical patients. A man able to pay for surgical attendance desires to be operated upon by a certain surgeon. Under present conditions he can go to the hospital, pay a moderate sum for a few weeks' board, and have the operation performed free by this same surgeon, who is not allowed to receive any compensation. Should the latter venture to remonstrate with the trustees of the institution because of this unfairness, he learns that others are ready to assume his duties should he find them irksome. The only remedy in the hands of the surgeon is to establish his own private hospital. Then from each one desiring his services can he receive a proper compensation. To reform this abuse we must go back to the trustees, who are not always able to discriminate between what are and what are not proper cases for admission. The charitable medical institutions were not devised for making money out of the profession. Such a procedure is a prostitution of their office and contrary to the spirit in which they were founded.

THE INOCULATION TREATMENT OF HYDROPHOBIA.

The daily papers have devoted much space recently to exploiting M. Pasteur's alleged discovery of a cure for hydrophobia. After experimenting for a year longer Pasteur has finally come before the Academie des Sciences again, and announced that he has succeeded in perfecting a method of inoculation by which human beings can be safely rendered insusceptible to the virus of rabies, even after it has entered the system. We have referred to Pasteur's first discovery, made over a year ago, viz., that one attack of hydrophobia in dogs protected against a second, and that such a protective inoculation could be made safely on dogs with a modified virus. So much seemed definitely established.

Pasteur's present claim has a wider range. He believes that his inoculation system is now so perfected as to be rendered practicable for application to human beings, both for protection and cure.

Pasteur's process, by which he prepares his virus and his subjects, is a very complicated one, and reads more like the performance of a conjurer than the methods of a scientist. A bit of the spinal cord of a rabid dog is inoculated in a rabbit. After about fifteen days this rabbit dies of hydrophobia. A portion of its cord is then taken and inoculated in a second rabbit, which animal also dies of rabies, after a somewhat shorter period of incubation. The cord of the second rabbit is used for the inoculation of a third animal, and so on until sixty rabbits have been destroyed by the inoculated disease. With each successive inoculation the virus gets stronger, and the period of incubation shorter until the sixtieth rabbit dies on the seventh day. Bits of the cord from the whole series of sixty are preserved in bottles of dried air, which has the property of weakening the virus. Thus M. Pasteur obtains a series of specimens of spinal cord having a gradual steady variation in specific virulence, from the very weak to the very strong. He now takes a bitten dog or man and inoculates it or him, first with the weak virus, then with virus successively of stronger and stronger potency, until finally the strongest and freshest specimen is used. Protection is then believed to be conferred.

That this process succeeds with dogs has been admitted, but the claim that it will succeed with man still rests on a very flimsy foundation, as will be seen from the reports given of the only two cases in which it has been tried.

A boy, twelve years of age, named Meister, who had been bitten fourteen times, came from Alsace with his mother to see Dr. Pasteur. The autopsy of the dog which had bitten the boy left no doubt as to its having suffered from hydrophobia. In thirteen days inoculations were made upon Meister with pieces of spinal marrow containing virus of constantly increasing strength, the last being from the spine of a rabbit that had died only the day before. At the time of the report one hundred days had passed since Meister underwent the last inoculation, and the boy was in perfect health. He had been bitten sixty hours, and had travelled from Alsace to Paris before the first inoculation was performed.

A shepherd boy, named Judith, aged fifteen, was bitten by a mad dog and had been a week under treatment when Pasteur reported his case.

It is well known that all persons bitten by mad dogs do not get rabies, and the evidence for Pasteur's hydrophobia cure is as yet mainly one of analogy.

As we stated a year ago, Pasteur's view is that all dogs should receive preventive inoculations or be Pasteurized, and thereby the disease of hydrophobia be entirely eliminated from the race.

CAREFUL VACCINATING.

There is a manifest tendency for small-pox to disseminate itself from its present epidemic centre, Montreal, and we may expect to find it cropping out here and there in the United States during the coming season. Epidemics of this disease are liable to begin in the autumn, and increase in violence during the cold months, owing probably to the crowding together of people at this season.

There should therefore be no delay on the part of all unprotected persons in getting vaccinated.

And since so much is now being said about the dangers and accidents of vaccination it behooves physicians to use extra precautions in employing this protective measure.

The virus generally used by American physicians is the bovine. This should be fresh, and obtained from a responsible source. The arm, before its vaccination, should be carefully cleansed, and the instrument invariably and thoroughly disinfected. The operation of vaccinating should, in other words, be done antiseptically, and the arm should afterward be kept from all septic influences. Such precautions will lessen the per cent. of unpleasant accidents, and will give to the physician the satisfaction of feeling that he has done his whole duty in the matter.

A SERIOUS MISREPRESENTATION.

We would call the attention of all fair-minded medical men to a persistent and graceless misrepresentation which is being made by the apologists of the present organizers of the Washington Medical Congress. It is announced by these gentlemen that the rules have been changed so as to allow all members of the regular medical profession to become members of the Congress. And it is repeatedly and with great show of liberality asserted that now all cause of complaint has been removed.

Gentlemen who write thus know very well that they tell a half truth. They know that not a physician in affiliation alone with the New York State Medical Society or county societies can hold an office in the Congress. They know very well that they have thus arbitrarily excluded some of our best and most honored physicians from all official part in the Congress, and yet we are informed, forsooth, that "now all possible cause of complaint is removed."

VACCINATION FOR WHOOPING-COUGH.

As long ago as 1828, Professor Chapman, of Philadelphia, recommended vaccination as a remedy for whooping-cough. The practice was purely empirical and on

its face a little absurd, nevertheless it has been kept up by physicians here and there, and now receives renewed advocacy in the *Cincinnati Lancet and Clinic.*

Dr. F. W. Entrikin, of Finlay, O., writes:

"I have vaccinated for this purpose several hundred children, and almost always with happy results, usually a speedy cure. During the many years I have been familiar with the practice I have seen no reason to discard it. I have frequently seen it recommended in medical journals."

He adds:

"I think it best to give the usual treatment until the febrile stage has passed, then vaccinate, the new disease set up by the virus will then usually arrest the nervous and other distressing symptoms."

Other contributors report favorable results from this apparently absurd method of treatment. No positive clinical evidence, however, is furnished.

CARBOLIC ACID IN INDIGESTION.

Nearly all writers upon the subject of dyspepsia recommend the use of creasote or carbolic acid as a remedy for gastric fermentation and eructations. Several physicians have recently called attention to the almost specific value of this carbolic acid in conditions where the stomach appears to be hyperæsthetic as well as filled with the gases of decomposition.

Dr. Fenwick, some years ago, recommended glycerine and carbolic acid in these conditions. Mr. J. F. Dixon, in a letter to the *British Medical Journal*, says that a few years later he was tempted to follow Fenwick's method, and try carbolic acid in indigestion associated with tenderness of the stomach, acidity, and flatulence. "In most instances," he says, "the result was very striking; cases which had proved very intractable yielding immediately to its influence. I used it of the same strength which I have always used for the eye; that is, two minims to the ounce of water, usually with the addition of five grains of carbonate of sodium and twenty-five minims of aromatic spirit of ammonia."

Mr. Edward Berdoe adds, in the same journal, that he has found carbolic acid most useful in fermentative dyspepsia, accompanied by sour risings and eructations of gas, with pain after meals.

"The dose," he writes, "is from five to ten minims, in mint-water or other convenient vehicle. As it mixes well, I think it a more elegant and safe form than a solution of the acid in water only. When there is much pain in the stomach after food, I have found it useful to add five or six minims of the liquor opii sedativus to each dose; and, when there is want of tone in the seat of digestion, and bad appetite, five to ten minims of the tincture of nux vomica will often be found serviceable. I have found these remedies also very valuable, in the above combination, in cases of pyrosis, where, I think, the sedative influence of the carbolic acid on the mucous membrane is far more useful than the bismuth one usually given in such cases."

Dr. Yandell says editorially in the *American Practitioner*: "Carbolic acid has for many years been much used by the physicians of Louisville in indigestions of one kind and another, and may be fairly said to have secured a permanent place among the remedies for this class of troubles. The late Professor Lewis Rogers, of this city, first gave it in a painful condition of the stomach, accompanied by eructations, in a woman convalescing from typhoid fever. The result was so satisfactory that he directed it in other cases, spoke of it in our medical societies, and led to its being very generally adopted by the profession here. In hyperæsthetic pyrosis it is particularly valuable; and in the fermentative diarrhœas, especially those accompanied by excessively offensive dejections, either in adults or children, it is efficacious beyond most drugs."

Altogether there is evidence that carbolic acid, by virtue of its two-fold powers of disinfectant and sedative, should play an important part in the therapeutics of dyspepsia.

AN OMINOUS SILENCE.

It appears very pertinent to ask whether the American medical profession has any rights at all in connection with the proposed Medical Congress. Is it not time that the proceedings of the secret meeting in this city be published? Is it not time to inform the profession who is to officer the Congress, that is, or perhaps is not, to be. Who is to supply the places of Professor Dalton in Physiology, of Dr. Shakespeare in Pathology, of Dr. Battey in Gynecology. What gentlemen have stepped into the places vacated by Professor Bowditch, and Dr. Campbell? It is not unreasonable, we think, to ask who is the unknown assistant to the Assistant Secretary-General, or who are the other officers of sections nominated to fill the one hundred and sixty odd vacancies.

It is now two months since the secret conference was held in New York. The profession still knows almost nothing of what it has done or proposes to do, except that its action has caused some of the best of the few representative men then appointed to resign. It is time to hear something besides long-drawn-out explanations and reiterated assurances that matters are progressing satisfactorily. The silence is ominous. It indicates surely that the reputable men of the profession are continually refusing to work with a clique that is selfishly determined to carry out its own views.

A REVIEW OF RECENT CONTRIBUTIONS TO THE THERAPEUTICS OF OBESITY.

The Americans, as a race, are not inclined to obesity. All the more, perhaps, do they dislike it when it comes. Anti-fat remedies, therefore, generally take very well with the laity, when properly advertised, while physicians are naturally always interested in scientific contributions to the therapeutics of obesity. Of late years there have been several of these, and recently Dr. Munk has presented a critical review of them. In addition we observe that, at a late meeting of the Académie de Médicine, Professor G. Sée presented his views upon the subject.

Dr. Munk, quoted in the London *Medical Record*, says Chambers, in 1850, excluded fat from the food, together with the greater part of the carbohydrates, and he was also the first to limit the supply of liquids. Dancel, in 1863, recommended plenty of albumen, a fair quantity of carbohydrates. and an allowance of between five hundred and twelve hundred and fifty grammes of liquid

Banting's diet (the name of his medical adviser, Mr. Harvey, should not be forgotten, and in Germany this method of reducing obesity is called the "Harvey-Banting" method) was almost purely albuminous. The proximate elements taken daily amounted to 170 grammes of dry albumen, 10 grammes of fat, and 80 grammes of carbohydrates. Banting reduced his weight by thirty-five pounds in nine months by this diet, and his girth by twelve and one-fourth English inches. The Banting diet deserves a closer examination. Fat exerts a protective influence over albumen; the greater the fat-supply, and also the fatter the body, the less is the destruction of albumen. In this diet no fat, and very little carbohydrates, is supplied, but plenty of albumen, which therefore partly undergoes destruction, and is partly deposited in the body, while the fat of the body is absorbed and reduced. The patient's condition improves in every way.

But the case alters as the body-fat lessens. With a higher albumen-condition and a lower fat-condition of the body, the conversion of albumen is greater, and more and more albumen is required in the food. Otherwise there is both fat-loss and albumen-loss, and when the latter occurs the patients feel very weak. Hence, the Banting *régime* is only suitable for the first few weeks, and both fat and carbohydrates should then be given, so as to restrict the albumen-changes in the body. As regards the protection of albumen, fat and carbohydrates are of about equal value; but, as regards the production of heat and the evolution of force, 1 part of fat = 2.4 parts of carbohydrates. The above diet, then, too rigidly carried out, soon makes the patients (or, at least, most of them) weak and wretched and sleepless; and very often dyspepsia arises, or gastro-intestinal catarrh, from failure to digest the albumen supplied.

Ebstein, therefore, arranged a different diet, in which there was more fat and less meat, and still less carbohydrates than in the Banting diet. This diet represents 100 grammes of dry albumen, 85 grammes of fat, and 50 grammes of carbohydrates, with about 1,750 grammes of liquid, and is far more non-nitrogenous than Banting's, and consequently there is less destruction of albumen in the body. Fat allays hunger sooner than other foods, and also the addition of fat to the food gives more variety.

The advantages of Ebstein's diet have been much vaunted, and his treatise, put in a popular form, has been widely disseminated. We have already pointed out that his views, as to the relation of fat-deposition to fatty food, had not a sound physiological basis, an opinion which has been corroborated by Voit. Moreover, Professor Oertel declares that Ebstein's diet is quite as likely to cause disgust as Banting's. It contains too much fat for the palate, and too little albumen for the tissues. This will be seen by the following table:

	Albumen.	Carbohydrates.	Fat.
Normal diet for a healthy adult..	130 grms.	360 grms.	90 grms.
Dr. Ebstein's diet.....	100 "	50 "	85 "
In the Harvey-Banting diet.....	170 "	80 "	10 "

It can be said in favor of Ebstein's diet, however, that it acts more slowly than Banting's, and, further, that its adoption is not recommended as being a specific and sudden cure, but as being a *régime* that must be followed for a long period of time.

Oertel's method of reducing obesity appears to be one that is gaining in popularity. If we mistake not, it was a *régime* stolen from Oertel that Schweininger applied successfully in the treatment of Bismarck. This author gives a fair amount of fats and carbohydrates, advises mountain-climbing as a cardiac gymnastic exercise, employs vapor-baths, prescribes pilocarpin, and enjoins a strict restriction of liquids.

Professor Sée reduces the hydrocarbons in the food to a minimum. He does not limit the amount of liquids drank (a fatal error in his *régime*). He imposes muscular exercise, warm baths, and small doses of potassium iodide. To tell the truth, his contribution to the therapeutics of obesity is not of great value, and in his special attention to the heart he appears to be only following the lines in which Oertel and others have worked.

News of the Week.

New York Physicians' Mutual Aid Association.—The annual meeting of the New York Physicians' Mutual Aid Association will be held in the hall of the New York Academy of Medicine, No. 12 West Thirty-first Street, on Thursday, November 12, 1885, at 4 P.M. A revision of the by-laws will be proposed by the board of trustees. A full attendance is requested.

Dr. C. E. Nelson has resigned as associate editor of the *Eastern Medical Journal*.

Report of the Surgeon-General.—General Murray, the Surgeon-General, in his annual report, submits estimates for the year ending June 30, 1887, amounting to $250,000. He says that provision should be made for emergencies, in view of the probability of an invasion of this country by cholera before the close of the ensuing fiscal year. Congress should make provision to enable this department to adopt every means to prevent the spread of this disease in the army. The general health of the army has been good.

Small-Pox in Montreal.—The small-pox shows no marked signs of abatement in Montreal, while it is slowly but surely disseminating itself throughout the Province. The local sanitary organization in the small towns is very imperfect and inefficient. In Montreal the disease has already caused the death, it is estimated, of over three thousand persons. The health authorities there have now become thoroughly aroused. They have obtained legal authority to isolate cases, and are trying their best to enforce vaccination. Still further, according to the daily press, the Health Board has unanimously declared that the public welfare demands the closing of the churches. This, if true, is a measure of very doubtful wisdom, considering the already strained relations between the health authorities and the people. A recent telegram from Montreal states that "The Vigilance Committee report that there are ten hundred and eighty-seven infected houses in the city which have not even been visited by the Health Officers. There are on an average two cases in each house. The contractors for the construction of the new Protestant hospital have struck work and nothing is being done. The Civic Board have been asked to erect a new hospital with fifteen hundred beds.

Trading in Clinical Material.—Complaints are made that some of the gentlemen connected with the out-door department of the New York Hospital send their clinical material to other institutions.

Small-Pox in the United States.—Small-pox is reported in Lowell, Mass., and St. Paul, Minn.

The County Insane Asylum at Chicago, Ill., has long been a disgrace to its managers, to the people who support it, and to the doctors who have been connected with it. If the medical profession in Chicago is not a completely impotent body, it should demand and insist upon radical reforms. Periodically we read some fresh stories in the daily press about this notorious asylum. The latest is as follows: Dr. Harriet Alexander tells a committee investigating the County Insane Asylum a horrible story of the treatment and surroundings of inmates of the asylum, when she was there last Spring. Three hundred patients are crowded into a space only large enough for half that number, two persons often being compelled to sleep on one cot. The bed-clothing in February last consisted of one sheet and one blanket. There were not dresses enough to go around, and some of the women patients could not go out, etc. As a result of these disclosures a memorial to the Governor is being prepared, asking him to direct the State Board of Charities to investigate the asylum.

The Production of Abortions.—In one week the dredge-nets of the Associated Press have circulated the news that three doctors, living respectively in Springfield, Mass., Chicago, Ill., and Madison, Wis., have gotten in trouble by producing abortions to conceal the results of adultery. We wish that our professional newsgatherers had less fondness for carrion, and more conscientiousness in describing the untoothsome morsels when found. It makes the story a better one to say that the doctor was previously "in high standing and large practice." The truth generally is that the doctor had neither standing nor reputable practice, and perhaps had no right to a medical title whatever. All the same, it does the profession injury to have such stories constantly reported and such deeds credited to regular physicians.

The New Building of the McGill University Medical College.—It is a pleasure to learn that medical colleges like that of McGill University, which have consistently devoted themselves to higher education, are prospering. The recent accession of a new building, finely equipped with laboratories, lecture-halls, museum, anatomical rooms, etc., marks an era in the history of the College.

Utilization of Criminals for Cholera Experiments.—Surgeon-General Cornish, in the *Indian Medical Gazette*, urges the propriety of using condemned criminals for the purpose of testing certain mooted points in the pathology of cholera. Why not use Ward?

Resignation from the Congress.—Professor John G. Curtis, of this city, states that on August 31st he addressed a letter declining to have anything to do with the Congress under its present organization.

German Opinion of the Washington Congress.—The *Centralblatt für Augenheilkunde* says that the success of the International Congress is unfortunately in doubt. "The American Medical Association has deposed the executive committee and sought to substitute another. We hope that this difficulty among the American doctors will soon be settled peaceably. The ophthalmologists of Europe would hardly feel inclined to attend a Congress with Agnew, Knapp, and others left out."

Economizing in the City Health Department.—The Board of Estimate and Apportionment cut down the estimates of the Health Department from $487,516 to $345,500. A great part of the reduction was in the matter of salaries, for which $221,000 was asked and $150,000 allowed.

A New Disease, which has been termed electric cholera, has made its appearance in Spain. A few weeks ago a violent thunderstorm passed over the town of Ecija, in the province of Seville, and two hours after it had ceased upward of three thousand persons were attacked by diarrhœa and vomiting, and all the symptoms of cholera. Two thousand more were attacked the day after. All these persons were completely prostrated for twenty-four hours, but recovered without any deaths occurring among them.

The Time of Day when Babies are Born.—A distinguished obstetrical professor seems destined to be shorn of one of his best annual lecture jokes, viz.: "Babies," he used to say, "are generally born at night, because their time is up!" The rude hand of the statistical investigator dispels this bit of facetiousness. Dr. Leaman, of Philadelphia, in an analysis of six hundred cases published in the *Medical Times*, finds that three hundred and nineteen were born between the hours of 6 A.M. and 6 P.M. The greatest number occurring during one hour, forty, was between 7 and 8 A.M. The least number, twelve, occurred between 12 M. and 1 P.M. Dr. A. W. Hamilton also combats, in the *Indiana Medical Journal*, the general belief that the majority of births occur during the night. He has kept a record on this matter, and finds that quite as many children are born during daylight as during the night.

Another Medical College in Detroit.—Evidently the *cacoëthes docendi* is upon the profession this fall. The *Medical Age* says: "There are rumors of another Medical College in Detroit, in the near future, and this in spite of the arguments which were employed to effect the amalgamation of the two schools which existed last year into the one which holds the boards this season."

New York State Medical Association.—The second annual meeting of this Association will be held in the Murray Hill Hotel, New York City, on November 17th, 18th, and 19th, and at the Carnegie Laboratory on the 20th, 1885.

Notification of Infectious Diseases.—If one may credit the City Board of Health Reports, there were hardly any fatal cases of the acute infectious fevers in this city, except typhoid, during the month of September last. We fear, however, that there is a very great laxity on the part of physicians in the matter of reporting these cases. And there always will be imperfect reports so long as the doctor is compelled by the State to do a service for which he receives no return.

New York Polyclinic.—Dr. B. Sachs has been appointed Instructor in Diseases of the Mind and Nervous System.

Washington Obstetrical and Gynecological Society.—At the annual meeting of the Washington Obstetrical and Gynecological Society, held on October 16, 1885, the following officers were elected for the ensuing year: Dr. A. F. A. King, President; Drs. W. W. Johnston and J. Taber Johnson, Vice-Presidents; Dr. C. H. A. Kleinschmidt, Recording Secretary; Dr. S. S. Adams, Corresponding Secretary; Dr. G. B. Harrison, Treasurer.

An Account, by a Member, of the Methods of the Secret Committee on the Washington Congress.—Dr. R. A. Kinloch, a member (now resigned) of the committee in question, in a letter to the *Medical News*, gives a striking picture of the doubtful and disingenuous methods employed by the committee at its secret meeting, held in New York September 3d. From an extract which we give below it will be seen that there is and has been no resolution of the American Medical Association forbidding the appointment of New Code or no Code men to office, and that the present position of the committee was the result of the personal prejudices of certain members of the committee. Dr. Kinloch writes: "The next matter which duty to myself compels me to notice has reference to the alteration of the rule, as adopted at Chicago, determining the American membership of the Congress. This rule had been fixed, as was claimed, *in obedience to the voice of the American Medical Association*, so as to restrict the membership on ethical grounds. The determination of a few adroit members of the committee was now to undo what had been done, and in their own peculiar way. By management more suitable for a political than a professional or scientific body, and which I will not now comment upon, the rule, as prepared for presentation to the committee, which it was claimed opened the Congress to all members of the regular profession, was finally brought before the body. I asked the gentleman who had introduced the subject whether, under the proposed rule, all members of the Congress would be alike eligible to office, and whether he would favor the election of any member of the profession simply upon his merits, or whether there was not a mental reservation upon the part of those suggesting the change by which, upon ethical grounds, certain members would be members merely, and debarred from holding office. The answer came, that, in accordance with the 'resolution' of the American Medical Association, certain parties must be refused high position. I asked for the reading of the 'resolution' referred to. I wanted to know whether the Association had ever drawn any such fine distinction, opening the membership to all, but restricting the distribution of honors. It turned out that there was no such resolution ever adopted by the Association. I then maintained that if the Association and its implied sentiment were to guide the committee upon this occasion, it was more consistent to hold on to the Chicago rule than to accept the amendment as now proposed. I offered to support the amendment with all my heart if this was honestly offered, and if the mover would amend it further by stating that all members were equally eligible to office, or if he would agree to show that, practically, all were eligible by voting for men on their merit and regardless of ethical standing. If this were declined, I insisted I could not vote for the amendment, for I would not pretend to offer bread and give a stone. My proposition was not accepted, but the new rule was adopted without my vote, and *all in the name of the Association*." No more damning evidence against the policy of the present organizing committee could be possibly furnished than the foregoing, coming, as it does, from a courteous and conservative gentleman, a leader in the medical profession of the South.

Reviews and Notices.

A System of Practical Medicine by American Authors. Edited by William Pepper, M.D., LL.D., assisted by Louis Starr, M.D. Volume I.: Pathology and General Diseases. Philadelphia: Lea Brothers & Co.

The editor tells us in his preface that he feels that the time has come for the presentation of the whole field of medicine as it is actually taught and practised by American physicians. We quite agree that an extensive and systematic treatise by American physicians is a good thing, both for publishers and physicians. Race, temperament, and climatic conditions give, undoubtedly, a peculiar physiognomy to many diseases, and develop special modes of dietetic and medicinal treatment. We welcome the appearance of an "American System of Medicine" therefore. But in the first volume there is very little distinctly American. European authors are much the most frequently quoted, and in articles such as that on "Epidemic Cerebro-spinal Meningitis," in which some deficiencies in pathological description may be noted, it is because foreign authors have not been thoroughly studied. In fact, there is not enough material in American medical literature or experience with which to build a system or even to stamp a system with any striking peculiarity. This is not saying that the present work is not a most thorough, satisfactory, and creditable one. Only it is largely and necessarily the same old subjects gone over again, the same clinical descriptions, the pathology a little more advanced, the treatment perhaps more rational and definite.

The first volume starts out with certain general discussions. Nearly a hundred pages are devoted to "General Morbid Processes," written by Dr. Reginald H. Fitz. Dr. Fitz is a sound pathologist, and well acquainted with the present status of this department of medical science. He gives a useful and correct *résumé*, although it is pretty dry reading, as most general discussions are.

Dr. Hartshorne has the difficult task of saying things in general regarding etiology, medical diagnosis, and prognosis. He has done as well as could be done with these subjects in fifty pages; but we think that they add little to the value of the treatise and are largely a sacrifice of the reader and publisher to the fetich of "The Systematic."

Dr. Billings' article on "Hygiene" is one of the most useful in the book. If we were adopting the arts of the auctioneer, we should say that it alone was worth the price of the treatise, as a chapter for reference and instruction to the general practitioner.

The remainder and larger part of the volume is devoted, under the term "General Diseases," to the acute infectious fevers.

The contributors here embrace a number of distinguished names, with some not so distinguished, a rather large proportion (of the former) being Philadelphia physicians. In general the articles show the marks of care and

industry. In many cases, as in the accounts of typhoid fever and cerebro-spinal meningitis, new facts or statistics are presented. We shall not venture to criticise the different articles separately. The only fault which can be detected is that the authors have in many cases ambitiously crammed in too much. Such endless numbers of references to what this or that German thinks of a disease's pathology or treatment tend to confuse, and many of these quoted opinions are quite worthless. We would not be thought hypercritical, however, and would state again that the discussions are, on the whole, thorough, systematic, and quite up to the latest advances in medical pathology.

THE PRINCIPLES AND PRACTICE OF SURGERY. By JOHN ASHHURST, JR., M.D., Professor of Clinical Surgery in the University of Pennsylvania, Senior Surgeon to the Children's Hospital, Consulting Surgeon to the Woman's Hospital, etc. Fourth Edition, Enlarged and thoroughly Revised. 8vo, pp. 1118. Philadelphia: Lea Brothers & Co. 1885.

THIS thoroughly practical work has now advanced to the fourth edition. A large amount of valuable matter has been added, necessitating an increase of fifty pages. It has now fairly earned for itself the reputation of a standard work on surgery, and is abundantly able to stand on its own merits. The author is a surgeon of large experience and a scholar of rare attainments, and as such he has infused a personality into his work which cannot fail to be appreciated by the student in quest of broad principles, or the surgeon who wishes to be guided by a master.

A PRACTICAL TREATMENT ON THE DISEASES OF CHILDREN. By ALFRED VOGEL, M.D., Professor of Clinical Medicine in the University of Dorpat, Russia. Translated and edited by H. RAPHAEL, M.D., formerly House Surgeon to Bellevue Hospital, etc. Third American from the eighth German edition, revised and enlarged. 8vo, pp. 640. New York: D. Appleton & Co. 1885.

THIS work has already made for itself a well-deserved reputation. It is concise, scientific, and practical in character. The author has had a large experience, and he makes logical and positive statements. The treatise has advanced to its eighth German and its third American edition. This fact, of course, speaks for itself. All that perhaps remains to be said is that the book still keeps abreast of the times in pathology and therapeutics. This would go without the saying, but the proof in the affirmative is apparent in every chapter. In the present edition much has been added to the chapters on artificial nutrition, dentition, and nervous diseases. The important subject of possible transmission of tuberculosis from the cow to the child has been very succinctly and critically discussed.

The various new remedies have been very fully detailed, and their employment in infantile diseases fully discussed. Dr. Raphael has added a very interesting and instructive article on cerebro-spinal meningitis. The volume has not been perceptibly enlarged.

FOWNES' MANUAL OF CHEMISTRY, THEORETICAL AND PRACTICAL. A new American from the twelfth English edition, embodying Watt's Physical and Inorganic Chemistry, with one hundred and sixty-eight illustrations. 12mo, pp. 1056. Philadelphia.

THIS chemistry has maintained its reputation as a leading text-book for students for over thirty years. In the meantime its author and editor have passed away. The former has been dead for many years; the latter, while contemplating a new work founded on Fownes' plan, died recently, with only a portion of his task completed. Prof. Watt's work was rendered necessary by the constantly increasing number of additions and corrections in successive editions under his supervision. It became in time more representative of the editor's than of the author's views. Hence it has been deemed best to comprise the work of both author and editor in a consistent form in one volume. As such it bids fair to continue its former popularity with students of chemistry.

A TREATISE ON NERVOUS DISEASES, THEIR SYMPTOMS AND TREATMENT. A Text-book for Students and Practitioners. By SAMUEL G. WEBBER, M.D. Pp. 415. New York: D. Appleton & Co. 1885.

IN such a work as Dr. Webber's, which lays no claim to originality, the reviewer can only commend the arrangement, the conciseness of statement, the perspicuity of style, and the judgment displayed. At the first glance one is led to question the desirability of adding another to the long list of books on nervous diseases which have already been published, but each year so much increases the knowledge of this department of medicine that the latest comer has the advantage and commends itself to the student as being up to date.

THE ESSENTIALS OF HISTOLOGY. For the Use of Students. By E. A. SCHÄFER, F.R.S., Jodrell Professor of Physiology in University College, London; Editor of the Histological portion of Quain's Anatomy. Philadelphia: Lea Brothers & Co. 1885.

THIS book is divided into forty-two lessons, as well arranged for use by students as any with which the reviewer is acquainted. The text is both well written and well illustrated. It is very evident, however, that the author did not intend to interfere with the sale of his "Course of Practical Histology" by writing this volume; but he has materially interfered with the success of the student in studying "The Essentials of Histology" by rendering it necessary to refer to another book for many of the practical details of his work. It will serve a good purpose as an elementary text-book of histology.

DE L'APHASIE ET SES DIVERSES FORMES. Par LE DR. BERNARD. Paris: Aux Bureaux du Progrès Médical. 1884. 8vo, pp. 271. Paper. Publications du Progrès Médical.

IN a recent editorial on the "New Divisions of Aphasia," in THE MEDICAL RECORD, much of that discussed by Dr. Bernard in the present volume was given. Our author has written an exhaustive memoir on the subject of aphasia, which will be of standing value for perusal and reference.

A TEXT-BOOK OF NURSING, FOR THE USE OF TRAINING SCHOOLS, FAMILIES, AND PRIVATE STUDENTS. Compiled by CLARA S. WEEKS, Graduate of the New York Hospital Training School; Superintendent of the Training School for Nurses, Paterson, N. J. 12mo, pp. 396. New York: D. Appleton & Co. 1885.

THIS is an admirably written book, and is full of those important practical details necessary for the medical and surgical nurse. In fact it could be read with profit by every medical student and young practitioner.

THE SANITARY CONDITION OF THE PROVINCE OF MILAN.—A commission, recently appointed by the prefect of Milan, to investigate the subject of pellagra, has made a long report upon the sanitary condition of the province, from which it would appear that there is considerable room for improvement in this direction. The report is presented in fifteen chapters, dealing with dwellings, water-supply, bread, schools, prevalent diseases, etc., and it has hardly a single word to say in praise, but many in condemnation. There is but little abuse of alcohol, and syphilis is prevalent only among young men who have returned from military service; but the people live in dirt and squalor, without the slightest regard for the most elementary rules of hygiene.

THE NUMBER OF MEDICAL STUDENTS IN THIS CITY is larger than ever before.

Reports of Societies.

THE AMERICAN ACADEMY OF MEDICINE.

Ninth Annual Session, held in New York City, October 28 and 29, 1885.

FIRST DAY, WEDNESDAY, OCTOBER 28TH—MORNING SESSION.

THE meeting was called to order by the President, ALBERT H. GIHON, A.M., M.D., of Washington.

Prayer was offered by REV. HENRY J. VANDYKE, JR., of New York.

The following gentlemen were elected Fellows of the Academy: Drs. S. M. Nelson, of Cambridge, Mass.; J. H. W. Chestnut, of Philadelphia, Pa.; Rufus W. Bishop, of Chicago, Ill.; E. E. Mariott, of Springfield, Mass.; George N. Acker, of Washington, D. C.; H. V. Logan, of Scranton, Pa.; H. W. Elmer, of Bridgeton, N. J.; H. F. Hansell, of Philadelphia, Pa.; E. W. Cushing, of Boston, Mass.; J. S. Wight, of Brooklyn, N. Y.; William Osgood, of North Yarmouth, Me.; C. A. Packard, of Bath, Me.; W. K. Oake, of Auburn, Me.; A. Mitchel, of Brunswick, Me.; D. A. Robinson, of Bangor, Me.; C. A. King, of Portland, Me.; J. A. Spaulding, of Portland, Me.; G. W. Marshall, of Milford, Del.; William A. Hugie, of Charleston, S. C.; J. B. Shapley, of St. Louis, Mo.; M. H. Post, of St. Louis, Mo.; C. E. Briggs, of St. Louis, Mo.; J. S. Alleymen, of St. Louis, Mo.; N. S. Davis, Jr., of Chicago, Ill.; and Charles Edgar Cook, of Illinois. Dr. Henry H. Smith, and Dr. S. Weir Mitchell, of Philadelphia, were elected to honorary membership.

The first paper was read by DR. ROBERT L. SIBBETT, of Carlisle, Pa., and was entitled "The Study of Medicine as a Means of Education."

DR. CHARLES MCINTYRE, of Easton, Pa., then read a paper on

MEDICAL SUPERVISION IN STUDENT LIFE.

This paper assumed that the times had changed; that modern life made a greater demand upon the time and energies of the individual to the detriment of his health and development. It was considered impossible to diminish tasks and give more time to rest and recreation. There is no way known to shorten the period of rest, so something should be done for recreation. The plan suggested was the usual one given by students on these subjects. A careful physical examination at the beginning of school life, and a series of graded bodily exercises under medical supervision throughout school life was recommended. The end aimed at is to give such tasks as will tend to strengthen the weaker parts.

DR. HENRY O. MARCY, of Boston, Mass., read a paper on

THE CLIMATIC TREATMENT OF DISEASE, WITH AN ILLUSTRATION OF WESTERN NORTH CAROLINA AS A HEALTH-RESORT.

The fundamental factors of the zymotic diseases were first reviewed from our present knowledge of the rôle of the bacteria, and the question of the wise adaptability of the individual to his surroundings was considered as the best definition of climate. A *résumé* of the latest investigations of climatologists was given with reference to, and the results obtained by, the mountain health-resorts of Europe and America. The deductions of the writer were that good must be looked for in the benefit to be obtained to the individual in the improvement of his resisting vital powers, and invigoration of his cellular tissue regeneration, rather than in the escape from his bacterial enemies. The larger portion of the paper was devoted to the consideration of this new and important phase of the question of climate.

The higher Alleghanies in Western North Carolina were described at considerable length, as offering mountain health-resorts of a character well suited to a variety of diseases. The deductions were based on a long tour of personal investigation made during the last summer as a sanitary study.

The meeting then adjourned.

EVENING SESSION.

The meeting was called to order at eight o'clock. The President, DR. ALBERT L. GIHON, A.M., M.D., read his annual address entitled

WHAT IS MEDICINE?

He said that the place of the Academy was not to be sought among the pathological, clinical, sanitary, and other national associations. It antagonizes none of these, but seeks to cement all into a compact unity.

Referring to the slow growth of the Academy, it was stated that one of the reasons was to be found in the fundamental condition of membership, restricting fellowships to graduates in medicine who have received degrees in letters by course. As the co-operation of every educated man interested in the objects of the Academy is desirable, he was of the opinion that the time had come when every limitation to fellowship should be removed, except the solitary requirement that the candidate shall be in fact, as in title, "learned in medicine," and in all else that this term implies, but he would make it impossible for any one unfit or unworthy to enter though he come with an armful of diplomas, has subscribed to the most inflexible of codes, and no matter what faculty, society, or institution he may be delegated to represent. The nominations should be accompanied with the fullest record evidence, and be made long enough to advance, from six to twelve months, to enable the council to determine each man's fitness.

Let us ask ourselves the question, "What is medicine?" If we look to this Academy for the answer, we shall find that it is the most profound and ennobling study that can engage the intellect of man. This is not the popular idea. Like other professions whose offices are called for by the disagreeable incidents of humanity, it is only tolerated as a necessity. Sham aristocrats look down upon it, others hire its members as they do their cook and cabman. In military and naval services they are sought to be degraded. The ministering to the suffering and afflicted is nowhere regarded as an outcome of the study of the stupendous and sublime mysteries of existence. In the national councils, in military and naval organizations, in civil administration, who thinks of giving a first place to the physician, although his are the mental attainments which fit him best for counsel in all that concerns the welfare and progress of the human race?

The science of medicine involves the knowledge of everything that relates, however remotely, to the existence of man, his place in nature, his origin, growth, and development, preservation and continuance. The prevention and cure of those abnormal conditions which tend to his destruction are but one chapter in the volume, which, coming near the end, cannot be read understandingly without the thorough comprehension and diligent study of all that precedes. Medicine is so far-reaching in its sources, and so connected with every other branch of knowledge, that he who would begin its study must first have drunk deep of the well-spring of human knowledge. Medicine is a science of such proportions that only a well-educated man can master it. This is not the view entertained by the profession at large.

Why should medicine be cheapened to every purchaser, and the college debase its teachings to their limited understanding?

What can medicine only be to the ignorant numbers who are annually mustered into the ranks of the profession? To these men it can have no other aspect than that of a trade. Many enter upon it as a money-making vocation. It was taught them as a source of pecuniary profit, and they practise it for the fees they

get. Manifestly, then, medicine is not the same to all men, even medical men. If improper men can be excluded from national service, why not from State, county, and city medical societies? This should be done for the protection of the community. Where a drug-clerk kills one victim by his carelessness, he saves a hundred by recognizing errors in physicians' prescriptions. [Examples from apothecaries' files were given.]

Preventive medicine has at last attained recognition as the highest aim of the physician's art. It establishes new relations of the physician to the social system. Preventive medicine has more to do than warding off epidemic visitations of great scourges. Its most important duty is to consider the impairment of health of growing children through the sanitary defects of our school system, the prevention of insanity, the repression of crime. It is too much to expect antidotes for every microscopic germ. The tiny swarms around us are at once friends and foes. If we do not antagonize them, they purify the air we breathe, the water we drink, the dirt we tread, and prey upon our natural waste; it is only our own folly that causes them to turn and rend us.

Reform in medical education has been hampered by adherence to existing methods. It will not do merely to establish adjunct chairs. The starting-point must be the requirements of a thorough preliminary education. Four annual terms are necessary. Descriptive anatomy and materia medica are enough for the first year; histology and practical microscopy, physiology in all its relations, and the mechanical processes of pharmacy should occupy the second year; hygiene, general pathology, and general therapeutics for the third year; special pathology, special therapeutics, the philosophy of medicine, medical history jurisprudence, and ethics for the fourth year. A fifth year may, with advantage, be devoted to clinical experience under supervision.

Is our estimate of medicine visionary, and have we sought the impracticable? Must we silence our voices because few care to hear, and cease our efforts because the task is difficult? Must we tread the beaten track, lest we offend prejudices, antagonize pecuniary interests, and upset established orders? Not on this account shall we hesitate, if the truth be with us. The ethics of medicine rightly denounce fraternity with charlatans and quacks. Is the dishonor less if we degrade a noble profession by admitting to its rights and honors those who are ignorant, illiterate, and incompetent?

SECOND DAY—THURSDAY, OCTOBER 29TH—MORNING SESSION.

The meeting was called to order at ten o'clock.

A resolution expressing the sympathy of the Academy with Dr. H. P. Farnham in his painful illness, was offered by Dr. H. O. Marcy and adopted.

The following resolution was adopted:

Resolved, That a committee of three be appointed by the President to report at the next annual meeting, instructed to prepare a statement of the best preliminary education for medical students, and also a statement of the minimum attainments which medical schools should require of students before admitting them to the study of medicine.

It was also resolved to appoint a committee of two, whose duty it shall be to report the requirements for a preliminary education of the various medical colleges in the United States and in Canada.

The following officers were elected for the ensuing year: *President*, Dr. R. Stansbury Sutton, Pittsburg, Pa.; *Vice-Presidents*, Drs. Lewis P. Bush, Del., S. J. Jones, Ill., R. L. Sibbet, Pa., and F. H. Gerish, Me.; *Secretary and Treasurer*, Dr. R. J. Dunglison, Philadelphia, Pa.; *Assistant Secretary*, Dr. Charles McIntire, Jr., Easton, Pa.

Pittsburg was selected as the next place of meeting, on the third Tuesday in September, 1886.

A paper on "Medical Evidence," by T. J. Turner, M.D., in the absence of the author, was read by the Assistant Secretary.

REPORT ON LAWS REGULATING THE PRACTICE OF MEDICINE IN THE UNITED STATES AND CANADA,

by Richard J. Dunglison, M.D., of Philadelphia, Pa., and Henry C. Marcy, M.D., of Boston, Mass., was read by DR. R. J. DUNGLISON.

The doctor said that so little change has taken place within the last twelve months, with reference to legislative restriction of the practice of medicine, that your committee might in a few brief sentences dismiss the subject with the statement of the actual work accomplished in this direction. The honest efforts of medical men and of others during the past year, to accomplish creditable results in the States for the suppression of quackery, have been unabating, but in several cases disappointment has been the only issue of their labor. Indiana and North Carolina are the only States in which any alteration in existing laws has been made.

The committee had entered into correspondence with medical gentlemen in the different States with regard to the working of laws for the regulation of the practice o medicine, and their replies were submitted.

DR. BENJAMIN LEE, of Philadelphia, Pa., read a paper on

HEALTH OFFICERS, ANCIENT AND MODERN.

The important position assigned to hygiene and State medicine during the past decade, is an evidence at once of the advanced stage of civilization, and of the dense and rapidly increasing population. It also indicates that long occupancy of the land by successive generations has, at length, overtaxed the regenerative and self-purifying energies of the earth, and that extraordinary methods have now become necessary.

Reference was then made to the honors bestowed on the officers of public health in ancient Rome, and the high esteem in which they were held. To this was largely attributed the excellent sanitary condition of that city.

The second portion of the paper was occupied with a consideration of the organization of Boards of Health. The first point made was that in selecting the material for Boards of Health, politics, in the bad American sense of the term, should be rigidly excluded. Where it is possible to avoid it, the members should not be elected by the people; especially is this the case in large cities.

Secondly, boards of Health should be composed chiefly of physicians; but at least one member should be a man eminent among his fellows for prudence and judgment in trade and commerce; for doctors are, proverbially, bad business men.

Thirdly, as it is desirable that there should be harmony of action and of sentiment between the municipal government and the Board of Health, there should be a representative of one on the other.

Fourthly, it is essential for the practical working of the Board that it should employ a paid agent, who shall devote as much time as is necessary to inspection and investigation of the sanitary conditions of the locality, and carry into execution the orders of the Board.

Finally, every member of the Board should receive a fair and even generous compensation for his labors.

AFTERNOON SESSION.

The meeting was called to order at two o'clock.

DR. SAMUEL N. NELSON read a paper, entitled

MICRO-ORGANISMS AND THEIR RELATION TO DISEASE,

describing the micrococci found in various diseases, the results of their culture, and giving a careful *résumé* of the literature of the subject.

The next paper was on

OBSERVATIONS OF THE RELATION OF BACTERIA TO CERTAIN PUERPERAL INFLAMMATIONS,

by Dr. Ernest W. Cushing, of Boston, Mass.

These observations were based on the results of examinations of the bodies of such women as died from these maladies in the general hospital at Vienna last spring. He called attention to the great difference between the customs and rules governing the obstetric assistants and students in Berlin and in Vienna. In the former city every precaution is taken to avoid not only direct infection, but also any possible carrying of germs in the hair or clothing, as if bacteria were freely present in the air. In Vienna, although the possibility of so finding them is admitted in theory, yet in practice the assistants and students are allowed to be present at autopsies. Obstetric operations and laparotomies are performed before the whole class without spray, and the chief assistants give operative courses on the cadaver every afternoon, relying for safety on washing, bathing, and change of clothing. Practically, sepsis arising in the hospital is very rare, and the results obtained by avoiding direct infection through the fingers and instruments were regarded by the speaker as an argument in favor of the view that puerperal fever is not an entity, the poison of which is carried about in the air and enters the system through the lungs, etc., but that such fevers are the result of invasion and multiplication of bacteria, arising from infection of the uterus or abraded vagina, as a rule, directly from hands, instruments, or applications.

Discussing the results obtained by the examinations above mentioned, the reader stated that the most frequent cause of infection was the strepto-coccus; the next the staphylo-coccus, with which is frequently associated the bacillus pyogenes fœtidus. The first occurs in chains not distinguishable from those of erysipelas, the cocci usually lying in pairs, each pair representing a link. The staphylo-cocci occur in bunches, like those of grapes. One or the other of the above were found in all acute cases examined, and were present in the uterine or iliac veins. In pelvic abscesses they were found in the lungs and joints, and, in fact, wherever metastatic abscesses occurred. Microscopic preparations of the above were exhibited, and three specimen cases described. Finally puerperal inflammations were compared to infected wounds. The powers of the system to resist, fence out, and kill the invading bacteria when the latter are not continually reenforced were emphasized, and an active hopefulness was advised in regard to treatment, which, to be successful, should be analogous to that of surgical wounds, *i.e.*, prompt removal of decomposing matter, evacuation of pus, cleansing and disinfective douches and drainage.

In discussing this paper, Dr. R. Stansbury Sutton said that while there was no question as to the success achieved by the use of antiseptics in general surgery, yet in abdominal surgery the best results so far had been obtained by strict attention to cleanliness, without the use of any antiseptic agencies. He agreed with Dr. Cushing that when the poison enters the abdominal cavity in laparotomy, or into the vagina or uterus in puerperal cases, the germs are not carried by the atmosphere, but by the hands, the forceps, ligature, or instruments. As far as abdominal surgery was concerned, he thought that all chemical agents could be discarded, but cleanliness could not be lost sight of. He then referred to the injurious effects which had at times resulted from the absorption of such agents through the peritoneal.

Dr. Henry O. Marcy related a case bearing on the introduction of antiseptics into the peritoneal cavity. It was that of a child four years of age, whose abdomen was filled with pus, in which the straptococcus was found. The pus was evacuated and the peritoneal cavity thoroughly washed out with bichloride of mercury solution. The patient recovered without a bad symptom.

"Medical Licenses and Medical Honors" was the title of a paper read by Dr. Edward Jackson, of Philadelphia.

A paper entitled "The Physician and his Patient," by Dr. J. D. Kelly, of Utica, N. Y., and one by Dr. Lewis P. Bush, of Wilmington, Del., "On the Physicians of Delaware in the Eighteenth Century," were read by title.

The President-elect was then introduced, and made a brief address.

The Academy then adjourned.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

Stated Meeting, October 22, 1885.

Alexander S. Hunter, M.D., Chairman.

Dr. Howard Pinckney presented a

HYDROCEPHALIC HEAD OF A COLT,

the mother and the foal dying during the process of parturition. There were only three cervical vertebræ present, but in other respects the body was normal. The face presented a striking resemblance to that of a bulldog, by which the mother was frightened during pregnancy. Dr. Pinckney, and also Dr. Garrish, thought that if craniotomy had been performed the life of the mother would have been saved.

Dr. Post remarked that deviation from the number seven cervical vertebræ was exceedingly rare in mammals.

Dr. John C. Peters donated eight bound volumes on obstetrics and kindred subjects to the Section, and accepted its thanks with the remark that all kinds of medical books, pamphlets, and journals would be received thankfully by the Academy, as they could be utilized in many ways for the benefit of the library.

Dr. Malcolm McLean then read a paper entitled,

THE MANAGEMENT OF UNFAVORABLE CEPHALIC PRESENTATIONS AT THE SUPERIOR STRAIT, ESPECIALLY THE OCCIPITO-POSTERIOR POSITIONS,

in which he advanced the view that these positions were essentially mal-positions, and that none were more important. He believed that more difficulty and delay arose from this cause than from all other causes of difficult labor, and the difficulty existed in the fact that the head of the child did not properly adjust itself to the pelvic canal. These positions should be recognized as early as possible, and be corrected at the earliest possible moment.

Short, abortive pains, recurring for hours in the first stage of labor, with the head high in the pelvis, excited his suspicion at once that the head was not properly engaging at the brim.

With reference to diagnosis by digital examination, he maintained that one suture could not be distinguished from another with satisfaction; nor, by means ordinarily practised, could the fontanelles be differentiated. The sense of touch by the finger could not be depended upon in recognizing the sutures and fontanelles; something more defined must be searched for, and that was *the ear*, and to do that the hand must, to a greater or less extent, be introduced. In order to have a perfectly sure appreciation of the exact position of the head, it was not enough to examine by digital touch only, but the hand must be introduced sufficiently to enable the operator to recognize the ears of the child, and at the same time the hand is made to appreciate the condition of the pelvic canal as well as the condition of the funis, which might be so situated as to prevent proper rotation.

A blade of the forceps should never be introduced before the hand has been introduced, and a complete exploration made.

What shall be done when these unfavorable positions

of the child's head are recognized? Flex the head properly with the hand, which, as a rule, could be done easily; rotate the occiput in such direction as will secure its descent over one of the anterior planes. But in certain cases the head of the child will not remain in the position in which it has been placed, and in those cases it remains to resort to either the forceps or to perform version. The forceps were most commonly resorted to, and, as a rule also, they slipped as often as they were used. Slipping of the forceps, Dr. McLean regarded as evidence of their misapplication in the case. Tarnier's forceps, as modified by Lusk, answered a most excellent purpose, but even that was an exceedingly powerful instrument and liable to do harm.

The treatment which he especially recommended was *podalic version* accomplished by the combined method. Version, properly performed, was the operation to be selected if the position could not be easily rectified, and, as an operation, it was less dangerous to both mother and child than the long forceps when applied at the superior strait.

Dr. Isaac E. Taylor opened the discussion and said that he had been surprised at the views advanced by the author of the paper. Conservatism was a great point in the practice of obstetrics, and never more so than while dealing with occipito-posterior positions. The statements of Naegele could not be set aside when he reported that he encountered only seventeen cases out of over seventeen hundred in which the occipito-posterior position terminated posteriorly. His views coincided nearly with those of Naegele, and his experience, during forty-five or fifty years, had shown that rotation anteriorly takes place in most cases, and that the rotation was favored by the planes of the pelvis, by the rigid action from the spine of the child, and by spiral uterine contraction which flexed the head. If rotation did not take place, certainly forceps should be applied. When the head of the child was in the pelvic cavity, and rotation has not occurred, certainly version should not be resorted to. It might, however, be made a face presentation, and he believed that many of the occipito-posterior cases became cases of face presentation without interference. Suppose the head is brought down into the pelvic cavity and it does not rotate, then push the occiput up with two fingers and make a face case.

With regard to diagnosis, he never was guided by either the fontanelles, sutures, or the ear, but by the general contour of the child's head occupying a certain portion of the pelvis; whatever segment was occupied by the occiput was filled so that the finger could not be swept around it, whereas the opposite segment gave sufficient room to sweep the finger around in all directions.

Dr. Taylor did not think it was necessary to introduce the hand to perform version, as it could be easily performed with two fingers aided by external manipulation.

Dr. W. M. Polk had been interested in the paper because the author took a position so strongly in favor of a view that was not generally accepted. As he understood from the paper, the writer rather held to the view that all cases of occipito-posterior position should be treated by version. If that was so, Dr. Polk thought it would be simply enlarging the domain of operative obstetrics, and rather recklessly, too. Of course, if the operation was performed, it must be when the child was high up in the pelvis, and before nature had done anything toward bringing about rotation.

Dr. Polk was also led to suspect that many of Dr. McLean's cases were really those of slight contraction at the brim, and in the absence of any statement on that point, was disposed to regard the difficulty encountered as due to slight narrowing at the superior strait, which was much more common in this country than writings on obstetrics would lead us to suppose. Wherever this slight deformity existed, labor was interfered with necessarily, and assistance would be required particularly by version, which he regarded as preferable to the use of the forceps.

With regard to diagnosis, Dr. Polk supposed that every man who used the forceps at the superior strait, never did so without the administration of an anæsthetic, and the introduction of the entire hand into the vagina and the fingers through the internal os, for the purpose of mapping out in his mind the position of the child's head. As for attempting to diagnosticate the position without the hand in the vagina, he would not think of it, as it was utterly impossible, as Dr. McLean had already stated.

So far as the general proposition laid down by the author of the paper was concerned, that cases of occipito-posterior position should be treated by version at the superior strait rather than by the use of the forceps, he was unwilling to accept it. If it could be shown that there was the slightest narrowing at the brim, or disproportion between the child's head and the pelvic cavity, he stood ready to resort to operative interference. But the paper meant to state, as he understood it, that version or forceps should be used for correcting a position of the child's head at the superior strait, which was regarded as a natural position, and which nature had shown herself capable of taking care of until the head was near the floor of the pelvis, where it could be reached by means of the forceps with little danger to the tissues of the mother.

When the head was low down in the pelvis it would not rotate, and then by all means interference by means of the forceps was demanded, because it was too late to resort to version.

Dr. Polk preferred to let his cases of occipito-posterior position alone at the superior strait, unless he found that there was difficulty in the engagement of the head, and then he put his hand into the cavity of the vagina, and endeavored to ascertain whether or not there was any disproportion between the child's head and the pelvis.

Dr. Taylor referred to the necessity of seeing that the shoulders rotated properly.

Dr. F. V. White spoke of the unreliability of the sutures and the fontanelles as aids in making a diagnosis.

Dr. H. Griswold reported a case of occipito-posterior position with narrowing at the brim of the pelvis, and in which he introduced his hand, rotated the head forward, and subsequently delivered with Tarnier's forceps.

Dr. McLean in closing the discussion said, that if his words had conveyed the idea that he desired to be a meddlesome operator, his language had done him great injustice. His intention was to inveigh against mischievous interference in these cases, and to advocate conservatism in the fullest sense. What he had said was, that in many of these cases rotation forward does take place and the children are delivered naturally. He also had said that forceps had been applied in many cases where no such operation had been needed at all. He simply turned to version instead of the use of the *long* forceps, and the cases in which he would interfere were those which were delayed on account of perversion of the first stage of labor. Inasmuch as these cases are tedious, practitioners are called upon to do something for the relief of the woman, because nature does not always rotate the occiput anteriorly. Certainly, such are sufficiently frequent to make the obstetrician seek for some means of relieving the patient. Where nature shows not the slightest inclination to bring the head down, if neither flexion nor extreme extension, changing it to a face presentation, occurs, something must be done.

The change into a face presentation, mentioned by Dr. Taylor, was an important point, and one which was inadvertently omitted from the paper.

If these cases do require assistance, the question arises, what shall be done? The general practice is to use some form of forceps, but Dr. McLean believed that this was not the best means for completing delivery, and that version was better adapted to such cases than the use of

the forceps; version to bring the head down where it can rotate.

His paper did not teach that *all* cases of occipito-posterior position should be treated by version; simply version in delayed cases, and not in all cases, by a very large majority.

With regard to contraction at the brim, that was not the condition in the cases referred to, and one good point in the evidence that there existed no narrowing was the fact that previous labors, with large children, had been completed naturally, and within the average length of time.

Dr. McLean was unprepared to believe that the average practitioner introduced his hand before applying the forceps.

The Section then adjourned to meet on the fourth Wednesday in November.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

OPENING OF THE SOCIETIES—THE OBSTETRICAL SOCIETY—DR. DUNCAN'S LUPUS OF THE VULVA SHOWN TO BE SYPHILIS—MR. HUTCHINSON'S OPINION—DR. DUNCAN'S REPLY—HIS REPUTE AS AN EXAMINER—OTHER EXAMINERS AT THE LONDON UNIVERSITY—THE CLINICAL SOCIETY—HÆMATAMESIS NEONATORUM—REMOVAL OF SAC IN HERNIA—TREPHINING—ABERNETHIAN SOCIETY—THE TEMPERANCE HOSPITAL.

LONDON, October 17, 1885.

CLOSELY following on the introductories at the schools comes the opening of the session of the medical societies. The Obstetrical leads the way, and on the 7th inst. we had a rather lively meeting. Dr. Mathews Duncan brought forward what he persists in calling "lupus of the vulva." At a former meeting he had read a paper on the subject, and now gave the sequel. On that occasion he was reproved as gently as his brother obstetricians knew how for calling the disease he described by a name which was otherwise employed, and with which they alleged it had no connection. Dr. Duncan did not take the rebuff at all kindly—he is not the sort of man to tolerate opposition to, or even questioning of, his opinions. He went on repeating his statements and teaching that "lupus of the vulva" was a distinct disease. At the opening of the society, then, this year, he was afforded the opportunity of re-stating his opinion, which he did in his usual dogmatic style. But his friends had prepared for him a surprise. They had no notion of settling the matter by assertion only. Many of them felt sure Dr. Duncan had mistaken syphilis for lupus, and secured the presence of that eminent and indefatigable syphilographer, Jonathan Hutchinson, who, with his natural courtesy and kindliness of manner, began his remarks by commending the clinical description of the cases, and then proceeded calmly, apparently unconscious of the bitter dose he was administering, to state that the cases had no relation whatever to lupus, but were simply manifestations of syphilis. Then he pointed out, as naturally as if teaching his class, that one of the cases was termed by Dr. Duncan "syphilitic," and in every one of the others, points in the history might have suggested if they did not prove that there had been infection of the constitution with syphilis. The effect of Mr. Hutchinson's speech was remarkable; there was a chuckle of delight among the majority, who felt that this settled the matter, and that Dr. Duncan had been deservedly "sat upon."

Dr. Thin ventured a few words in support of Dr. Duncan on histological grounds, and Dr. West tried to offer him some support, but it was very feeble. All the other speakers disagreed, and when Dr. Duncan got up to reply he was at white heat. Lupus, he declared, was a convenient term; it was well understood; the disease had a large literature. He did not assert that it was quite identical with lupus vulgaris; but, as for syphilis, to accept such evidence as Mr. Hutchinson had mentioned, was unreasonable—the "most unreasonable thing he had ever heard of." Rather strong language this, but what remained to be said by a man who disdains to learn. Any one could see that the whole audience regarded Mr. Hutchinson's verdict as final, and the only interest that continued to attach to the meeting was curiosity as to how Dr. Duncan would comport himself under his mortification.

Obstetricians are not remarkable for their mutual love and self respect, but in this instance the delighted chuckle goes far beyond the circle of the society, for though a very able and learned man, Dr. Duncan does not find grace in the eyes of many practitioners, and still more, students. He may be genial and jocose among his intimates, but his bearing and manners are self-assertive and uncouth, and at the examination-table he is dreaded—just as his brother Scotch professor, Rutherford, was—and the contemptuous expression "Scotch manners" is applied to both by men who have had to face them. Last year at the University of London, a question was set in obstetrics, which excited the condemnation of most of the teachers of the subject as manifestly unfair; it was entirely as to hæmatokolpos, a condition (which might well puzzle any one who forgot the meaning of the Greek word kolpos) which is not described in any of the ordinary text-books under that name, although it is in Dr. Duncan's own lectures, and which is so rare that very few cases have been described in obstetrical literature. Of course, Dr. Duncan got the credit of setting the question, but his co-examiner on the occasion, Dr. John Williams, might perhaps have proposed it; at any rate he must have sanctioned it, and therefore should share the blame. It is perhaps as well for Dr. Duncan that his term of office as examiner has expired, and he may perhaps never again seek a position for which he is ill adapted. It may not be much better for students, for Dr. John Williams is reported, even in his own school, to be, with all his ability, anything but a pleasant acquaintance across an examination-table.

It is one great fault of the London University that its examinations may be conducted by persons whose only qualification is that they are appointed by the Senate—being mostly persons who have attained a certain reputation in the subject either as teachers or authors—and so students are subjected to the crotchets of a series of experts on numerous subjects, and some of these experts have shown themselves destitute of all sympathy with students, and otherwise ill qualified for their tasks. I could give you illustrations in the several faculties, but must return more strictly to medical subjects, and especially our societies.

The Clinical Society resumed work on the 9th under the presidency of Mr. Bryant. Here Dr. Sawtell related a case of hæmatemesis and melæna in a new-born child, fatal in the course of twenty-four hours. The first time blood was vomited was about twenty-one and a half hours after birth, up to which time milk had been taken, and the vitality was not very low. The hemorrhage continued, mixed with meconium and mucus, and the child soon sank. At the autopsy there were small, deep, round, and oval ulcers at the cardiac end of the stomach near the lesser curve. Dr. Sawtell had not found the record of a precisely similar case after extensive search. I find that Dr. Goodhart's book recognizes that gastric ulcers may occur in the new-born, and attributes the cause to disturbance of the circulation incident to the closure of placental supply and the commencement of aerial respiration. Dr. Crocker compared this case to purpura neonatorum. This, when confined to the skin, usually does well, but when it affects mucous membrane is naturally more formidable.

Mr. Lucas next related two cases of strangulated hernia treated by excision of the sac and skin covering, with

suture of the ring after reduction. He was not induced to adopt this procedure by the desire to effect a radical cure, though this was an incidental advantage, but with the hope of reducing the mortality. He looked on the sac as a danger, and wished to rid the patient of the ill-nourished, over-strained abnormal tissue with its liability to slough, suppurate, and collect discharges, or guide them into the peritoneal cavity.

Both the cases were umbilical, and it was suggested by the president that the discussion should be confined to that form. There was a considerable difference of opinion evinced—and that was among Guy's surgeons, where the operation has been most done—thus proving that there is room for careful study of the subject. Mr. Barker had practised the method successfully. Mr. Howse thought each case should be treated on its merits, and where the sac was healthy its removal would increase the risks of the operation. In strangulated hernia delay constituted the chief risk, so only a few hours should elapse before an operation was undertaken. Mr. G. Bird endorsed the practice, but not the explanation. The practice had for some years been adopted. Mr. Walstrom had cut away the sac in twelve cases—three umbilical, seven femoral, and two inguinal. Unless seen long afterward, and no truss had been worn, he should not say they were radical cures. Mr. Makins had recently operated in a similar way on one case. Mr. Ballance removed the sac and many square inches of skin, and as much omentum as possible. Mr. Symonds said when the sac was small it was not necessary to remove it; in femoral hernia he always removed it. Mr. Godlee did not think complete separation of the sac easy to do, as it was so closely united to the skin over a large area. Mr. Hopkins operated on a man of seventy, who had softening of the brain, but the operation was recovered from.

The next subject was trephining for compression of the middle meningeal artery by a clot. Mr. Charters Symonds related a case in which he had trephined, and after much difficulty arrested the hemorrhage. The man recovered consciousness, and on conclusion of the operation he gave his name and address, but the next afternoon pulse and temperature rose, he became delirious and sank. It was suggested that compression of the carotid might be useful in such cases, and Mr. Bryant had noticed in an American journal an article on ligaturing the carotid for such cases. Altogether the Clinical had a good opening meeting.

The Abernethian Society is the St. Bartholomew's Students' Society, and is sometimes frequented by older "Bart's men." This year it was opened on the 8th with an address by Morrant Baker, who traced the early history of old Bart's to its foundation of centuries ago by Rayer or Raherus, and gave a number of curious gleanings from the early chapters of this long story.

The other London Societies will open next week. The provincial societies do not all observe the same period as those in the metropolis.

The Bishop of London on the 9th inst. opened the new wing, containing seventy beds, of the Temperance Hospital. He gave an address in which he recognized the value of medical services. The bishop (Dr. Temple) is a strong supporter of the temperance cause, and the President of the National Temperance League. In the hospital the mortality has been low, and alcohol only prescribed about once in a thousand cases.

There may be various reasons why alcohol is less called for than in former days. But whatever be the explanation, there is no doubt that it is much less prescribed, and no one can say that practice is less successful.

The hospital has done good service in emphasizing the fact, and proving how little alcohol is necessary; but even without this, no doubt the thoughtful investigations of therapeutists would have done something to check the indiscriminate prescription of alcohol which proved so injurious.

From the time when the late Professor Parkes spoke out, the Temperance party has been making steady progress in the medical profession.

The references to the matter in the introductories has opened the floodgates of the controversy on the right of London students to the degree of M.D.; the obstinate policy of the London University, which is driving men from the metropolitan schools, and the relative value of various diplomas—all knotty subjects, and to some degree unprofitable, but with which we are again to be overwhelmed, for no statesman seems inclined to take up the grievances of the profession and settle our differences.

TYPHO-MALARIAL FEVER.

To the Editor of The Medical Record.

Sir: In your last issue, among the proceedings of the Section in Practical Medicine of the New York Academy of Medicine, I am credited with the following remark (p. 502): "I believed that there was such a thing as typho-malarial fever, and did not believe that it was the same disease as typhoid fever." What I meant and hoped to say was this: That there are *complications* of typhoid and malaria. The sickness, as I have observed it repeatedly, runs, in most cases, a long course. For weeks no other diagnosis can be made but that of typhoid, for there is high fever (though not necessarily with the regular curves to which we are treated in the books), swelled spleen, also roseola, and the intestinal symptoms with or without diarrhœa. The fever will not, or but little, diminish toward the end of the third week and continues into the fourth or fifth week. About that time chills will (may) make their appearance. In well-pronounced cases I have observed two distinct chills, at more or less regular hours, with more or less perspiration following, through a period of from six to ten days. Quinia has not such a prompt effect as in the common uncomplicated form of malarial fever. There is no complete apyrexia, but a moderate remission only; then, instead of two daily chills there will be but one, and this will disappear after awhile, to be followed for some time by a fever with the remittent type.

Yours very respectfully,

A. Jacobi, M.D.

110 West Thirty-fourth Street.

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 25, 1885, to October 31, 1885.

Huntington, D. L., Major and Surgeon. Detailed on Board to inspect Army and Navy Hospital Buildings, at Hot Springs, Ark. S. O. 245, A. G. O., October 24, 1885.

McElderry, Henry, Major and Surgeon. Granted leave of absence for four months, from November 1, 1885. S. O. 246, A. G. O., October 26, 1885.

Patzki, J. H., Captain and Assistant Surgeon. Appointed member of Board to meet at Forts Jackson and St. Philip, La., on November 5, 1885, to select a site for the new quarters for the Ordnance Sergeants at those posts. S. O. 230, Department of the East, October 28, 1885.

Tousey, G. H., Captain and Assistant Surgeon. Granted leave of absence for two months, to take effect after the return from leave of absence of Surgeon J. C. Baily (Major). S. O. 87, Division of the Atlantic, October 24, 1885.

Barrows, C. C., First Lieutenant and Assistant Surgeon. In addition to his other duties, to take temporary charge of office of the Medical Department of the Division of Arizona. S. O. 102, Department of Arizona, October 17, 1885.

Ewing, C. B., First Lieutenant and Assistant Surgeon (Fort Leavenworth, Kans.). To accompany Congressional Committee, of which Hon. W. S. Holman is chairman, in its visit and inspection through Indian Territory. S. O. 160, Department of Missouri, October 23, 1885.

Ives, F. J., First Lieutenant and Assistant Surgeon. Relieved from temporary duty at Fort Laramie, Wyo. Ter., and ordered to Fort D. A. Russell, Wyoming. S. O. 106, Department of the Platte, October 22, 1885.

Morris, E. R., First Lieutenant and Assistant Surgeon (recently appointed). Assigned to duty at Fort Bayard, N. M. He will continue on detached service under orders of District Commander. S. O. 160, Department of the Missouri, October 23, 1885.

Medical Items.

Animals as Medical Practitioners.—M. G. Delaunay, in a recent communication to the London Biological Society, observed that medicine as practised by animals is thoroughly empirical; but the same may be said of that practised by inferior human races, or, in other words, by the majority of the human species. Animals instinctively choose such food as is best suited to them. A large number wash themselves and bathe, as elephants, stags, birds, ants. In fact, man may take a lesson in hygiene from the lower animals. Animals get rid of their parasites by using dust, mud, clay, etc. Those suffering from fever restrict their diet, keep quiet, seek dark and airy places, drink water, and sometimes plunge into it. When a dog has lost its appetite, it eats that species of grass known as dog's grass (*chien dent*), which acts as an emetic and a purgative. Cats also eat grass. Sheep and cows, when ill, seek out certain herbs. An animal suffering from chronic rheumatism always keeps, as far as possible, in the sun. The warrior ants have regularly organized ambulances. Latreille cut the antennæ of the ant, and other ants came and covered the wounded part with a transparent fluid secreted from their mouths. If a chimpanzee be wounded, it stops the bleeding by placing its hand on the wound, or dressing it with leaves and grass. When an animal has a wounded leg or arm hanging on, it completes the amputation by means of its teeth. A dog, on being stung in the muzzle by a viper, was observed to plunge its head repeatedly for several days into running water. This animal eventually recovered. A sporting dog was run over by a carriage. During three weeks in winter it remained lying in a brook, where its food was taken to it. This animal recovered. A terrier hurt its right eye. It remained under a counter, avoiding light and heat, although it habitually kept close to the fire. It adopted a general treatment, rest and abstinence from food. The local treatment consisted in licking the upper surface of the paw, which it applied to the wounded eye; again licking the paw when it became dry. Animals suffering from traumatic fever treat themselves by the continued application of cold, which M. Delaunay considers to be more certain than any of the other methods. In view of these interesting facts, we are, he thinks, forced to admit that hygiene and therapeutics, as practised by animals, may, in the interest of psychology, be studied with advantage. He could go even farther, and say that veterinary medicine, and perhaps human medicine, could gather from them useful indications, precisely because they are prompted by instinct, which are efficacious in the preservation or restoration of health.

A Proposed Remedy for the Abuse of Medical Charity.—Dr. Charles E. Young, of 334 West Fifty-ninth Street, suggests that the Charity Organization Society be asked to investigate every applicant for dispensary relief, and he suggests that the following or some similar plan be adopted by the various institutions: "Let all dispensaries issue similar cards to applicants for gratuitous treatment. On the back of these cards shall be printed the following rules: I. Upon receiving this ticket from the dispensary, the patient, in person or through a representative, must take it to the office of the Charity Organization Society, No. 79 Fourth Avenue, to receive the signature of the Society, before a second treatment at the dispensary can be expected. II. All applicants for free treatment must expect investigation from the Society at their homes. III. In return for services rendered patients will be expected to exhibit themselves for scientific purposes, if requested to do so, at any time and place named by the physician in charge of the case, and to return again for treatment if desired by him. IV. Failure to comply with these rules, or loss of this card, will forfeit the right to further treatment. The other side of the card may contain the usual lettering of the dispensary by which it is issued, space being left for the signatures of the Charity Organization Society and of the physician in charge of the case. The following rules are to be made known to each dispensary physician, so that all may understand and act together in the work: I. Whenever a patient appears for the first time, treat him if the case be doubtful, but call attention to the rules on his card. All cases known to be unworthy may be turned away without investigation, and if any money has been received by the dispensary from him it must be refunded. II. No money beyond the regular dispensary charge must be accepted from patients at the dispensary. III. Any patient appearing a second time without the signature of the Charity Organization Society upon his card must be turned away without further treatment. IV. Any physician not complying with these rules thereby severs his connection with this institution."

Franklinism in Medical Practice.—Mr. C. W. Meyer writes concerning the machines now generally in use for the production of statical electricity, and believes that were they simplified, and thereby reduced in cost, the general adoption of this useful therapeutic agent in medical practice would be greatly facilitated. He thinks that the air-tight glass case, which is one considerable item in the cost of the machine, might very well be dispensed with. It is true there would then be some days in which the machine would not work, but these days are relatively few, and the inconvenience experienced at such times would be counterbalanced by the greatly reduced price of the instrument. Mr. Meyer believes that a good fourteen-inch plate original Holtz machine will answer every purpose for the general practitioner, and by reason of its great cheapness, as compared with a self-charging air-tight machine, is within the reach of everyone.

The Danish Name for It.—In several notices which have appeared of late in the *Hospitals-Tidende*, concerning the next meeting of the International Medical Congress, and the causes which seem destined to prevent its being held in this country, mention is constantly made of the American med. ass., Am. med. ass., or A. m. ass. Why does the organ not protest against such levity?

An Extemporaneous Test for Human Milk.—Dr. Helot says that it is possible to judge with sufficient accuracy of the quality of human milk by comparing the number of drops in a given quantity of milk with those in a like amount of distilled water. Of course, the absolute number of drops will vary according to the diameter of the delivery tube, but the relative proportion will remain the same. This proportion should be about six drops of milk to five of water. The best instrument for measuring is the ordinary hypodermic syringe, made to contain one-half drachm of fluid. If now at a temperature of 58° F. it requires thirty drops falling from the end of the needle to empty the syringe, we should get at least thirty-five drops of milk, and if there are thirty-six or thirty-eight drops it is so much the better. Milk which gives no more than thirty-three drops to thirty of distilled water is not good, Dr. Helot says, and it will be necessary to secure another nurse in such a case.

Restoration to Sanity Following Erysipelas.—A case is reported by Dr. Landerer, of a young girl suffering from melancholia, who was attacked with erysipelas of the face and scalp. There was abundant suppuration, and it was necessary to incise the scalp in several places. Upon recovery from the erysipelas it was found that the mental disturbance was completely and permanently cured.

A Rush for Priority.—An amusing circumstance was related in a report presented recently to the Academy of Medicine of Paris. It appears that M. Brondel had announced that by means of electricity he could cause medicinal substances to penetrate into any of the tissues or even to pass entirely through the body. He endeavored to prove this in the presence of some members of the Academy by means of the starch test with iodide of potassium. The experiment did not succeed until, the starch compress becoming disarranged, the manipulator readjusted it. The characteristic iodine coloration at once became visible, but it was shown that there was iodide of potassium on the experimenter's fingers, not having been washed off carefully, and M. Blondel very frankly acknowledged his mistake. But the joke was that between the time that he had announced his discovery and had found out his error, numbers of communications had come from all sides from different electricians claiming priority in this grand discovery, which was to revolutionize therapeutical science.

Hyperembryohydrometrotrophy.—This is merely another name for pregnancy.

Sea-Voyaging as a Cure for Barrenness.—Surgeon-General Charles R. Francis writes to the *Indian Medical Gazette* an instructive and suggestive letter upon the subject of the influence of sea-voyages upon the genital function. As will be seen, sea-voyaging is at times a therapeutic measure of prodigious, not to say dangerous, potency. Dr. Francis says: "A young lady in India, of leuco-phlegmatic temperament, and remarkable for want of energy, which was conspicuous even in her languid mode of speech, had been married for seven years without any prospect of having a family, there not having been the slightest indication of pregnancy during the whole of this period. The husband was also young, and in good health. Being, however, of a kindly disposition, and never expecting to be as ladies wish to be, etc., Mrs. A—— surrounded herself with pets—small dogs, birds, and a monkey. At the end of the seven years she accompanied her husband (a civilian) to England on furlough. They went by the long sea-route round the Cape (of Good Hope). In those days—I speak of thirty years ago—a voyage home in a sailing-vessel (one of the large passenger ships of the time) was very invigorating. A comfortable cabin—one's own private residence for three months at least, so different to the comfortless system of berths in a general cabin in a so-called overland steamer—the soothing influences of the sea, the tonic air, etc., all combined, provided one was abstemious in the matter of food and intoxicating drinks somewhat freely provided in most of these vessels, to produce (in good sailors) a vigorous state of health, which, coming after a lengthened sojourn in a hot climate, was especially enjoyable. The lady became pregnant on board; and the activity of the reproductive function (thus roused) being maintained for several years, even after the return to India, this pregnancy was followed by others; and, as a matter of fact, a child was born annually for ten successive years, the deficiency of the first septennial period being rather too prolifically made up afterward. I have been six times round the Cape in passenger vessels and four times overland, and I quite believe in the stimulating effect—not always for good—of a sea-voyage (long or short) upon the ovario-uterine organization. In prescribing this remedy, however, in cases of sterility, the medical practitioner might, with the experience of that just related, be inclined to pause, feeling that possibly his patient might hereafter tax him with having prescribed rather too much of a good thing!"

Da Costa on the Treatment of Pulmonary Consumption—*Hygienic Treatment.*—Out-door exercise, good food, warm clothing; climate of paramount importance. The best climate, by far, is that found in Egypt; Algeria is a good place. In this country, New Mexico, Southern California, South Carolina, Thomasville in Georgia, Florida. Colorado, for some cases, is an excellent climate. Cases having a co-existing bronchitis do better in a damp and mild climate, as Florida, etc. The element of change is very useful. The Adirondacks is a fine place for those early cases in which there is no tendency to hemorrhage. Prof. Da Costa does not care much for the "milk diet," but allows it in conjunction with other things. Give plenty of meats, and alcohol in moderation, especially in those cases free from fever. Mix it with ol. morrhuæ, to lessen the tendency to its abuse. Whiskey and brandy are the best stimulants here. You need not interdict smoking.

Medicines.—Ol. morrhuæ is of great utility by improving nutrition and also by affecting the tubercle. Do not use its substitutes, as glycerine, etc. Give f ℥ ss. ter die, one hour after meals. To disguise it, and to promote its ready absorption, give ♏x.–xv. ether, but this sometimes causes belching. Mix it with equal amount of malt or whiskey. When the appetite fails stop its use for a while. Do not permit the oil to be taken in hot weather. Next in importance is arsenic in small doses in the early stages; arsenious acid, gr. $\frac{1}{60}$, or gtt. iij. Fowler's solution, ter die. In the late stages it will be of no avail. A third remedy is iodine; it should be more generally used; liq. iodi comp., gtt. i.–iij. ter die, with potassium iodide to alternate with it. When anæmia is present, *and not much fever*, use iodide of iron. It is very valuable. Push it up to the point of tolerance. Begin with gtt. xv. of the official syrup, and push up to f ℥ j. ter die. Prof. Da Costa does not like the hypophosphites. They have no special effect, as ol. morrhuæ and arsenic. Inhalations of sodium benzoate are of no use. Carbolic acid and tar by inhalation are of some avail.

Treatment of special symptoms.—Entirely too much is done for the symptoms. For cough we should give no expectorant, unless bronchitis exists. Since the cough is generally an irritative one, morphia must, in time, be given. Codeia, gr. $\frac{1}{2}$–$\frac{1}{4}$, in simple elixir, often has a wonderful effect and does not constipate. Prussic acid or fluid extract of wild cherry is very useful at times. We may combine the acid with morphia. Inhalations of oil of eucalyptus give relief.

Night sweats.—Give atropia, gr. $\frac{1}{60}$, at bed-time. Sponge off the body with hot water to constringe the vessels. Infusion of sage at night. Mineral acids, especially sulphuric acid. Zinc oxide, gr. ij. ter die. Ergotin or fluid extract of ergot is better than morphia in some respects. It is more permanent and does not cause dryness. Give ergotin, gr. ij. ter die, the last dose at bedtime.

Digestive system.—The patient often has vomiting. Two excellent remedies may be given, as carbolic acid or creasote, gr. $\frac{1}{2}$, four times per diem. Strychnia, gr. $\frac{1}{30}$, ter die, is also of great value.

Diarrhœa.—Opium, bismuth, ʒj.; copper sulphate, gr. $\frac{1}{12}$; silver nitrate, gr. $\frac{1}{4}$, etc.

The throat in phthisis.—It may be swollen, and the larynx the seat of ulcers, which may become tubercular. Drink demulcents, as Irish moss (ʒ j. to the O j.).

Prof. Da Costa has confidence in local applications of iodoform and cocaine. Let the patient eat his meals while the parts are under the effect of cocaine.

For *irritative fever*—

℞. Quininæ sulph..... gr. jss.
Digitalis..... gr. ss.
Opii..... gr. $\frac{1}{4}$.

Original Lectures.

THE PROGNOSIS AND TREATMENT OF SYPHILIS.[1]

BY P. A. MORROW, A.M., M.D.,

CLINICAL PROFESSOR OF VENEREAL DISEASES IN THE UNIVERSITY OF THE CITY OF NEW YORK; SURGEON TO CHARITY HOSPITAL.

GENTLEMEN: Before taking up the subject of the treatment of syphilis, it may be well to direct attention briefly to the prognostic significance of the early manifestations of this disease.

The prognosis of the chancre, viewed in the aspect of a local lesion, is almost always favorable. In studying the clinical history of the initial lesion we have seen that it rarely gives rise to pain or other subjective symptoms, that it is limited in extent and duration, with a tendency to spontaneous resorption, and that it heals ordinarily without a cicatrix.

When complicated with phagedena, gangrene, or other inflammatory conditions, the local consequences may be more serious, resulting in more or less extensive destruction of the tissues, sometimes mutilation of the glans, urethral fistulæ, etc.; but, as a rule, the local process is a very simple affair.

But when viewed as the starting-point of a disease permeating the entire organism, capable of causing the most profound lesions, and practically indefinite induration, the prognosis is of much graver import.

No other infectious disease exhibits such a vast difference in its impress upon the organism, in the multiplicity, intensity, and duration of its symptoms, as syphilis. In some cases syphilis shows itself as essentially a mild disease, with slight and occasional manifestations, which, after a few months, cease altogether, and the patient remains to all appearances perfectly well. In other cases it is a most formidable disease; it determines a vast array of morbid manifestations, and may continue to reveal itself by destructive processes during the lifetime of the individual. Clinically, then, we must distinguish between mild and severe cases of syphilis.

Now it comes to be a question of great practical interest, whether we can trace a definite correspondence between the initial expression of syphilis and its subsequent manifestations. What are the relations between the source of the virus, the period of incubation, the anatomical characters of the chancre, etc., and the ulterior evolution of the disease? Can we, from a study of these initial characters, gain valuable indications which will enable us to forecast the future of the patient?

As regards the *source of the virus*, it may be very confidently asserted that it exerts no appreciable influence upon the character either of the chancre or of the constitutional accidents. Whether the contagion be derived from a primary or secondary lesion, whether from a simple erosion or a deep ulceration, is immaterial. It does not affect either the activity of the poison or its effects upon the system. It was formerly thought that the virus of a phagedenic chancre carried with it a more intense infective capacity, a greater potentiality for mischief; but we now recognize that phagedena is not a characteristic of the chancre; it is a property of the individual, and is, therefore, not transmissible.

In reference to *the period of incubation*, certain authorities have formulated the rule that the longer the incubation the milder the syphilis, and the shorter the incubation the severer the syphilis. This theory would seem to rest upon a rational basis, since the more prompt invasion of the system would seem to be an evidence of a feebler capacity of resistance. Unfortunately, however, clinical experience furnishes so many exceptions to this rule that its prognostic significance is of little value.

The next element of prognosis is to be sought for in the chancre itself—its induration, ulceration, and other specific characters. Does the *local action* of the virus upon the tissues, as revealed in the primary lesion, constitute a criterion by which we can estimate its *general action* upon the system? In other words, is the first visible manifestation of syphilis to be accepted as a correct index of its subsequent manifestations? Chancre has been termed the touchstone of the constitution, and we may assert very positively that a phagedenic chancre always portends a bad type of syphilis, for the reason that the phagedena is an expression of a bad state of the patient's constitution, which will probably be reflected in the character of the general accidents. In general it may be said that the more benign the chancre the greater the probability that the secondary accidents will be of mild type; but this correspondence does not always extend to the tertiary stage, since, as pointed out by Fournier, the severest forms of visceral syphilis often follow a chancre so insignificant as to pass unperceived by the patient. On the other hand, clinical experience furnishes many examples of a severe chancre, with voluminous induration, followed by a syphilis of mild or of medium severity.

We perceive, then, that the anatomical characters of the chancre do not always bear a definite relation to the character of the constitutional accidents.

Advancing a step further, to the advent of constitutional symptoms. After the disease has blossomed forth upon the skin and mucous membrane, does the first crop of eruptive accidents foreshadow the character of succeeding crops? Undoubtedly the early development of a pustular syphilide indicates a severe type of syphilis, and the same may be affirmed of the precocious development of ulcerative lesions; but, as a rule, it must be confessed that the benignity of early secondary symptoms does not furnish an absolute guarantee against the malignancy of tertiary manifestations. We must conclude, then, that the initial characters of syphilis do not furnish infallible signs which enable us to prognosticate the severity and duration of its processes. Our prognosis must be based upon conditions relating to the individual rather than to the disease.

We come now to the consideration of the treatment of syphilis. A patient presents himself to you with a recent chancre; you recognize this lesion as the starting-point of a long train of constitutional disorders, which may continue to recur during his entire lifetime. A most important question now arises; is it possible, by destruction of this lesion, to nip the disease in the bud, to prevent infection of the general system?

Now, many authorities very positively assert that excision of the chancre will abort syphilis, and that even when total destruction of the syphilitic virus is not effected, that by removing the mass of infective material contained in the chancre, the severity of its constitutional effects is modified. They assume that the virus remains for a time localized at its point of entrance, and that the

[1] Abstract of a lecture delivered at Charity Hospital, New York, October 31, 1885.

chancre constitutes the infecting source from which contamination of the system gradually takes place.

In discussing the pathology of syphilitic infection, I have already given you my reasons for believing that the chancre is the expression of a generalized blood-poisoning, the evidence of an already accomplished infection; and if this be the case, obviously enough destruction of this lesion, by excision or cauterization, will not arrest or modify the effects of the virus upon the general system.

Without attempting to determine at what precise time generalization of the virus takes place, but leaving all theoretical considerations aside, it may be safely asserted that the value of the abortive method has been settled by the test of clinical experience; the practice of excision of the chancre is condemned by its results. Numerous cases are on record in which the operation has been done under the most favorable conditions, within a few hours after the first appearance of the chancre, and yet constitutional symptoms followed in regular order.

The treatment of the chancre should be mainly expectant. The indications of treatment may be summed up as follows: cleanliness, the removal of local causes of irritation, and a simple protective dressing. When there is a tendency to suppurative action, mild astringents, dusting with iodoform or calomel, or the use of the black wash, may be employed. When the chancre is painful, the use of sedative lotions, as the lead and opium wash, will be found beneficial. Mercurial or other ointments should never be employed, especially when the chancre is situated upon a mucous surface. The voluminous indurations which sometimes remain, even after cicatrization, are removed by the unaided efforts of nature alone; their involution may, however, be hastened by the internal employment of mercury.

The next question which arises in connection with treatment is, whether the internal use of mercury in the primary stage prevents secondary accidents, or materially modifies the subsequent severity of the disease? This may be answered very decidedly in the negative. Mercury does not prevent the development of general symptoms; it may possibly delay secondary manifestations, it may derange the regular order of their appearance, but it does not prevent them.

This leads to a consideration of the proper time for beginning the general treatment of syphilis. Upon this point there is a difference of opinion among authorities. Many recommend the administration of mercury upon the first evidence of induration of the sore; others counsel its delay until after the appearance of secondary accidents. The latter plan is the most judicious. It is not always possible to pronounce with absolute certainty upon the syphilitic character of a venereal sore before secondary symptoms appear. There are so many possible sources of error in forming a diagnosis, that even the most practised physician may be deceived. Unless you have the elements of a positive diagnosis unmistakably present, you may accept it as a safe rule that it is better to defer specific treatment until secondary symptoms have declared themselves.

In the general treatment of syphilis an immense number of drugs, drawn from both the mineral and vegetable kingdoms, have been employed, but of this number only two are regarded as possessing *specific* properties. These two drugs, mercury and iodide of potassium, constitute the basis of all special therapeutical treatment at the present day. It is well, gentlemen, that you should have a definite understanding of what may be accomplished by the specific treatment of syphilis, and while appreciating the full measure of its therapeutic value you should also recognize its limitations.

It can be justly claimed for mercury that it exercises a positive curative action upon the secondary manifestations of syphilis, it abates their intensity, and hastens their involution. In the treatment of the erythematous papular and papulo-pustular eruptions, its action is often prompt and decided, causing a much more speedy disappearance than would have taken place in the natural course of the disease. Mercury also exercises an undoubted influence upon some of the later lesions of syphilis. Iodide of potassium is, however, the remedy *par excellence* for lesions of the tertiary stage, especially those of the gummous type. The rapidity of its action in melting away gummatous deposits, and in arresting ulcerative processes, is often marvellous. Affections of the bones, visceral lesions, etc., also come within the range of its curative action. A combination of these two drugs, constituting the so-called "mixed treatment," is often more efficacious than either alone, especially for the lesions of the intermediary stage.

But while clearly appreciating the *curative* action of these drugs upon specific lesions, we must recognize the fact that their *preventive* action is much less pronounced. Mercury does not prevent the evolution of syphilis; successive crops of secondary accidents continue to recur in patients under the full influence of an active mercurial treatment. We cannot affirm positively that mercury given continuously during the entire secondary stage will prevent the development of tertiary lesions. It is a matter of common observation that many syphilitics who have never taken a grain of mercury or iodide of potassium, never have tertiary lesions. Tertiary manifestations are not a constant or essential feature of syphilis, they occur in only a small proportion of cases whether the syphilis is healed or not healed, so that it becomes difficult to discriminate between the effects of treatment and the self-limitation of the disease. It would hardly seem reasonable, however, to suppose that a drug which is powerless to prevent successive outbreaks of the disease during its active employment, should be able to dominate the diathesis years later, and long after its discontinuance. We may conclude, then, that while mercury is the most efficient agent that medical science has yet discovered in the treatment of syphilis, it does not infallibly cure the diathesis or furnish an absolute safeguard for the future.

There are certain principles pertaining to the use of mercury in the treatment of syphilis, which clinical experience has established as fixed and definite, which I will now endeavor to formulate for your guidance.

Mercury should be given in small doses, and never pushed beyond the production of its primary physiological effects. It is an error to suppose that large doses are necessary to secure the full therapeutic efficacy of the drug. Mercury, judiciously administered in small doses, exercises a decidedly curative action on the secondary manifestations of syphilis, and its continuous and prolonged use may prove inoffensive to the patient. But, when given in doses sufficiently large to produce salivation and other toxic effects, it is positively pernicious. Unfortunately, we are not able to give the exact dosage in all cases, for the reason that susceptibility to the action of mercury varies in different individuals. Its influence upon the eruption and the toleration of the patient's system should be the measure of the dose.

Another point of importance is that mercury should not be given indiscriminately in all cases, irrespective of the condition of the patient's general health. In weak and debilitated patients, in certain cachectic conditions, mercury often does positive harm, and it should be employed with extreme caution. In malignant, precocious syphilis, for example, when the system seems to be saturated with the poison of syphilis, when the disease exhibits itself in its most intense and destructive form, mercurial treatment would only aggravate the condition. In these cases tonics, good food, stimulants, and all measures calculated to promote nutrition should first be employed. After the general health has been built up by reconstituent remedies, and not until then, will the syphilitic manifestations promptly respond to the action of specific treatment.

As regards the activity and duration of specific treatment, we cannot lay down arbitrary rules which shall apply in every case. The two principal plans of admin-

istering mercury in the treatment of syphilis are known as the "tonic treatment," by the continuous use of small doses, and the "intermittent treatment." By the continuous method the dose of mercury is gradually increased until it produces slight salivation, which constitutes the "full" dose. One-half or one-third of this quantity represents the "tonic" dose, which is continued for two or three years, with an occasional resort to the full dose when more active symptoms appear.

By the intermittent plan the effect of the mercury is carried to the point of toleration, and maintained there for two or three months; its use is now intermitted for two months and then recommenced, intermissions alternating with periods of active treatment from two to four years. Both these methods are open to objections. The principal objection to the first is that the continuous, prolonged use of the drug exhausts the patient's susceptibility to its influence; to the second, that the intermission of treatment may coincide with an active outbreak of the disease, when the remedy is most needed.

A broader, and, in my opinion, a much more rational rule, is to regulate the activity and duration of the treatment by the manifestations of the disease; in other words, the treatment should be essentially symptomatic. When manifestations appear, they should be suppressed by specific treatment; when they cease, the treatment should be remitted in activity or substituted by tonics, with a view of counteracting the emaciating and debilitating influence of the diathesis.

Various preparations of mercury are employed in the treatment of syphilis. The drug may be given in the form of metallic mercury or one of its salts. The choice of the preparation and the mode of its introduction into the system are often a matter of choice on the part of the physician. The administration of the drug by the mouth, either in pill form or in solution, is the most convenient and the most generally employed. My own preference is for the protoiodide in the form of pills, each containing one-sixth grain. The quantity of the drug ingested can thus be regulated with precision, and increased or diminished according to its effect upon the disease and the tolerance of the patient's system. If it should produce symptoms of gastro-intestinal irritation which cannot be controlled by combining it with opium, another preparation may be substituted, or the drug may be introduced through the skin. This is the oldest method of employing mercury in the treatment of syphilis, and still retains its popularity with many physicians. When mercury cannot be given by the mouth, the inunction method is no doubt the best substitute. It is also indicated in conjunction with internal treatment when the disease is active, threatening the integrity of important structures, and it becomes necessary to secure the speediest possible effect of mercurial action. For the purposes of inunction blue ointment, the oleate of mercury, or mercurial soap may be employed—the former is undoubtedly the most efficient in its action, although the oleate is the more cleanly and elegant preparation.

Mercury may also be employed by fumigations or mercurial baths, but they are rarely relied upon in the systematic treatment of syphilis. They serve rather as an adjunct to other methods, when it is desirable to obtain prompt and decided effects.

The hypodermatic introduction of mercury is a comparatively recent innovation upon older and established methods. It possesses the advantages of great convenience, combined with scientific accuracy. It is also claimed that the maximum effect of mercury is obtained with the minimum dose, while it produces neither stomachal nor intestinal irritation. It has the counter-balancing disadvantages of causing intense pain, with the occasional production of tumors and abscesses at the seat of puncture. Various preparations of mercury have been employed for subcutaneous injections, as calomel, the bichloride, the bicyanide, sublimate serum, the formamide, the albuminate, the peptonate, the urate of mercury, etc. The proper place of hypodermic medication among our therapeutical resources against syphilis has not been definitely determined. Its disadvantages are such that it will probably never supersede the older and more classic methods.

Toward the close of the secondary stage, and in the intermediary stage, mercury may be advantageously associated with iodide of potassium, the quantity of the iodide varying according to the ulcerative tendency of the lesions. Iodide of potassium finds its special application in the tertiary stage of syphilis. In tuberculo ulcerous lesions, serpiginous ulcerations, gummatous lesions of the subcutaneous tissues, bones, and internal organs, its curative action is remarkably rapid and efficacious, but it should be understood that, while it causes tertiary lesions rapidly to disappear, it does not prevent reoccurrence.

The local treatment of syphilis has always been regarded as merely accessory to general treatment, but recent experience with the dermic and hypodermic method has shown that mercury directly applied to the seat of syphilitic eruptions exerts a much more rapidly curative action than can be gained from its internal use. The topical use of mercury finds its special application in a late stage, when the eruptive elements are massed or aggregated in limited areas instead of being diffused over the entire surface. The lack of time forbids my considering in detail the local treatment of syphilitic lesions.

It is, of course, gentlemen, not possible within the limits of a single lecture to give more than a mere outline of the treatment of syphilis. We cannot lay down fixed and absolute rules of treatment which shall be adapted to every case. The activity and duration of treatment should be gauged by the intensity, the succession, and the duration of the syphilitic manifestations. Each case should be treated upon its individual merits. Benignity or malignancy of the type of syphilis is the product of peculiarities of individual constitution, and the indications are to treat the patient rather than the disease.

Common observation shows that syphilis is most severe in persons of broken-down constitutions, in persons suffering from privation, want and misery, of intemperate habits, the scorbutic and cachectic, persons in the extremes of life, where vital resistance is feeblest. In view of this fact, I am fully persuaded that the tonic and hygienic treatment of syphilis, embracing all measures calculated to build up and maintain the general health at the highest possible standard, are scarcely subordinate in importance to specific treatment itself. The patient's food should be of the most nutritious character, his surroundings good, his habits regular, overwork and exposure should be avoided, while alcoholic and venereal excesses should be prohibited. In conjunction with specific treatment, or in its intermissions, you should give bitter tonics to improve the appetite, ferruginous and nutritive tonics to invigorate the patient's constitution and increase his powers of resistance.

A Definition of Gout.—At the meeting of the Medical Society of London, on October 26th, Dr. Milner Fothergill read a paper on "The Presumptive Diagnosis of Gout." He described a gouty individual and exhibited casts of gouty teeth and photographs of gouty nails. He said: "When kidneys first appear in the animal kingdom the form of urinary excretion is uric acid. Uric acid belongs to animals with a three-chambered heart and a solid urine (reptiles and birds). The mammalia possess a four-chambered heart and a fluid urine; the form of urinary excretion being the soluble urea. When the human liver becomes depraved or degraded, it has a tendency to form primitive urinary products. To the question, What is gout? the answer is: Gout is hepatic reversion, when primitive urine is formed by a mammalian liver!"

A CASE OF COCAINE-POISONING SIMULATING OPIUM-POISONING.[1]

By J. S. SPEAR, M.D.,
MEDICAL INSPECTOR, UNITED STATES NAVY.

H. A. G——, private, U. S. Marine Corps, aged twenty-nine, weight, one hundred and forty pounds, general health good, on duty at the United States Marine Barracks in the city of Brooklyn, returned from liberty at 8.30 A.M., October 16th. He was one hour and a half over time, and being slightly under the influence of liquor was confined in a cell with three other prisoners. About 10.45, the same morning, he administered to himself with a hypodermic syringe "a dose to sober up," as he told his fellow-prisoners. He prepared the medicine and syringe himself. One of the men in the cell pinched up the skin of patient's arm for the insertion of the needle. After conversing very sensibly for half an hour without showing any signs of excitement or exhilaration he sat down on the floor with his back against the wall, and soon fell asleep.

At 12.40 P.M. the men in the cell noticed that his face was ashy pale, hands and lips quite blue, and large drops of perspiration covered his forehead and ran down his cheeks. They now became alarmed at his condition, and signalled to the sentry on post for help.

At 12.50 P.M., Mr. Louis, the apothecary of the barracks, reached the cell. He reports that he found the patient sitting on the floor with his back against the wall, and the body inclined to one side at an angle of forty-five degrees, resting on his elbow, head down on his breast, eyelids tightly closed, mouth half open, pupils contracted to a point not larger than the head of a small pin, breathing very slowly; pulse feeble and fluttering and not countable, face congested and of a whitish-gray color, lips and hands quite blue, body bathed in cold perspiration; unable to rouse patient by violent shaking and pinching. Mr. Louis thought the man was dying.

At 1.10 P.M. Dr. Derr, U. S. Navy, arrived. He says the patient was in a comatose condition; face cyanosed and puffy; pupils very much contracted; skin cool and bathed in perspiration; respiration very slow and almost imperceptible, and not at all stertorous; pulse slow and of fair volume. A diagnosis of opium-poisoning was at once made by the doctor. He used the stomach-pump directly, but found the stomach empty. A solution of the sulphate of atropia, one-eightieth of a grain in eight minims of water, was next injected hypodermatically, and strong coffee was forced down the throat and into the stomach by manipulation, patient at this time being quite unable to swallow. Two strong men lifted him on his feet and dragged him along the floor, while another man spanked him on the legs and buttocks. Under this treatment, in the course of an hour and a half, he showed signs of returning consciousness.

After taking coffee several times he finally vomited it. At 3.15 the writer saw the patient. Pupils were still much contracted and not responsive to light; pulse 80, and of fair volume; respirations 9 per minute and not stertorous; could be roused without difficulty, but inclination to go to sleep very marked, and would fall into a profound slumber if let alone for a few seconds; able to stand erect for a short time, but could not walk. Diagnosis concurred in.

At 5 P.M., respirations, 15; pulse, 92; walked alone, but staggered badly; pupils contracted; so much improved that all treatment was discontinued, except the guard was ordered to see he was not permitted to sleep longer than five minutes at a time.

At 8.30 P.M., the writer being present, patient was allowed to sleep one hour undisturbed, At the expiration of that time he was roused without difficulty. His temperature in mouth was 96.7°, and in axilla, 96°; pulse, 84, full and strong; respirations, 14; pupils normal and responsive to the light of a candle. No headache; said he is much fatigued and very sleepy. The following morning this man told me that his occupation is a hospital nurse; that he is addicted to the use of cocaine to allay a craving for alcoholic stimulants; that on the afternoon of October 15th he left the barracks about two o'clock, went directly to the manufacturing laboratory of Dr. Edward R. Squibb, in Brooklyn, purchased two small vials, each containing five grains of muriate of cocaine in powder, dissolved the same by filling the vials with water which he obtained in a bar-room; he then crossed over to New York, had his hypodermic syringe repaired at an instrument-maker's shop, and at about 3.30 P.M. gave himself the first hypodermic of cocaine, probably about one grain.

He had already taken several drinks, and continued to drink from time to time all night, going from one saloon to another. Every few hours he took a hypodermic of cocaine. He thinks he was not intoxicated at any time, is quite sure he did not spill any of his cocaine, but took it all before he returned to the barracks at 8.30 A.M., except the last portion, which he took in the cell as before related.

He declared most positively that he did not purchase nor take any morphia on this occasion, and indeed never took a dose of morphia in his life, and offered to make an affidavit to that effect. There was no evidence of suicidal intent. The purchase of the cocaine was confirmed by inquiry made at Dr. Squibb's laboratory. We were told that the same man had frequently purchased cocaine there before. The two vials with Squibb's cocaine labels on them, both empty, one corked, were found in the cell. Both showed unmistakable signs of having recently contained cocaine and not morphia. His own hypodermic syringe had been used to administer the atropia, so that an examination of its contents for cocaine or morphia was considered unreliable. Lastly, here on the spot I am really at a loss for any motive this man could have had for making a false statement as to the drug he administered to himself in the cell.

Very fortunately the routine of the prison is such that by taking a little trouble we have been able to fix the time of the occurrence of the events above related with a good deal of accuracy.

[1] Published by permission of the Surgeon-General of the Navy.

THEORIES OF CHOLERA AMONG THE CHINESE.—In a paper read at one time before the Society of Japanese Studies in Paris, the eminent sinologue, M. Léon de Rosny, related some of the views of cholera as held by the Chinese. The disease is called by the name hoh lwan, meaning the diarrhœa trouble or the quick trouble. Two varieties are recognized, kan hoh lwan, or the dry, and shi hoh lwan, or the moist, cholera. The latter is considered the more grave form. Chinese physicians believe that cholera may be communicated in one of three ways: 1. By proximity or contact with clothing worn by a patient. 2. By breathing air which has passed over cholera dejections. 3. By moist atmosphere during a storm. They say that the stools are never contagious as long as they are exposed to the direct rays of the sun, but that, when preserved in the shade or during the night, they become a source of great danger.

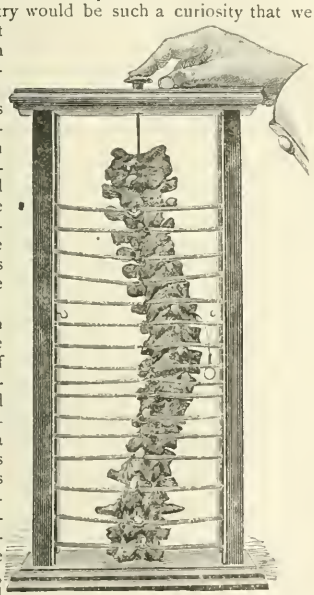
THE MECHANISM OF A LEECH-BITE.—M. Carlet states that the bite of a leech is effected by the three jaws, which bury themselves in the skin by a movement of separation, at the same time opening the œsophagus in the form of a funnel. When the top of this funnel is filled with blood, the jaws close and force the fluid along by a sort of piston movement. He asserts that there are no peristaltic movements of the œsophagus, but that the blood is driven along by the opening and closing of the jaws.

THE TREATMENT OF LATERAL CURVATURE OF THE SPINE.

By A. B. JUDSON, M.D.,

NEW YORK.

If this disease were simply lateral curvature the reduction of the deformity by mechanical means would be easy. Except in extreme cases there is no alteration of the bony tissue, which in Pott's disease prevents restoration of form. If the trunk simply curved laterally it would be comparatively easy to support it laterally in such a manner as to abolish the curvature. But there is an element in this disease which refuses to yield to this simple treatment. I refer to rotation, which is present whenever the spine curves laterally, in health as well as in this disease. But, although constantly present, this element easily escapes detection. It failed entirely of being described till the year 1824. I doubt whether previous to that year there is a single unequivocal reference to it in medical literature. And it is this obscure element that has insidiously thwarted the practitioner of orthopædic surgery in the treatment of the disease. For I suppose it will not be denied that a case of confirmed and well-marked lateral curvature in which the patient has been restored to perfect symmetry would be such a curiosity that we may frankly admit a doubt that such a case has ever existed.



That rotation is the intractable element is clear when we consider attentively the dried specimen or the mounted preparation[1] shown in the cut, which exhibits lateral curvature and rotation.

It is evident from inspection that the anterior portion of the vertebral column has curved more than the posterior portion, a condition of things which constitutes rotation. The anterior part, composed of the vertebræ being within the cavity of the chest, is entirely beyond the reach of direct mechanical impressions. Whatever lateral force is to be used must be applied by way of the ribs to the posterior portion of the column, composed mainly of the vertebral processes. Force thus applied largely tends to increase the rotation without straightening the curvature.

The force here spoken of is directed from the surface of the trunk toward its centre. If we could use a gyratory force, or one which would untwist the vetebral column, our mechanics would indeed take an important step in advance. But this force would have to untwist the column from right to left in one portion, and from left to right in another, for the rotation of the compensating is in a direction opposite that of the primary curve.

I therefore decline, as a rule, to treat lateral curvature with braces. There are exceptions to this, as to every rule. For instance, in some cases, by the use of a brace making antero-posterior pressure, as in Taylor's brace for Pott's disease, it has seemed possible not only to give to the patient the comfortable sensation of being supported, but also to push in the ribs from behind, or the transverse processes in the lumbar region, and thus to oppose rotation. But in general I have obtained good results by the persistent use of special exercises, in which suspension and the production of extreme lordosis when the patient is suspended, and also when lying supine, are the principal features.

HISTORY OF A CASE OF FOREIGN BODY IN THE THROAT, WITH OPERATION FOR ITS REMOVAL.[1]

By R. F. CHAPMAN, M.D.,

NEW YORK.

At four o'clock on Sunday afternoon, September 27th, a little baby of six months and twenty-seven days was seated on the floor of its home in a large tenement-house, when its mother noticed it put a piece of veal-bone which it had picked up from the floor into its mouth. This provoked a fit of coughing, and the child seemed to be choked, whereupon the mother forced her finger into the child's throat and dislodged the obstacle, and relieved, as she thought, the bad symptoms, for the child remained quite comfortable till nine o'clock that night, when another attack of difficulty from the piece of bone occurring, I was hastily summoned.

On reaching the patient I could not feel satisfied that the piece of bone had lodged in the trachea or œsophagus, for there was no cough, and the breathing only at times seemed to be affected by any obstruction.

Hoping it had entered the stomach-pipe and thereupon be the easier dislodged, I improvised a probang of a whale-bone and a pledget of cotton tied firmly to the end, which I passed into the stomach. For awhile the child seemed much relieved, and I thought there was reason for the hope that the obstruction had been removed. The breathing, however, was of a croupy character, but the child slept some and was generally more quiet. Hoping the difficulty was removed I left the child to the care of its parents, with instructions that if its breathing became labored during the night to call me.

I did not hear from it till next morning at nine, by which time I was quite possessed of the impression that my little patient had gotten over its trouble, when the father came to tell me that the child was worse and refused to nurse. I saw something decided had to be done, and at once determined to see my neighbor, Dr. D. C. Cocks, whom I knew, by oft-repeated experience, would cheerfully give me his skilful assistance, and whose success in tracheotomy made it most fortunate that I had him to call upon.

Dr. Cocks readily consented to see the case with me at once. Upon a most careful examination the foreign body was located in the trachea. An immediate operation was determined upon, and as soon as we could get ready —procure the anæsthetic and suitable instruments—Dr. Cocks proceeded to operate. Dr. G. H. Cocks, who has also had much experience in this operation, kindly assisted. An opening was made into the trachea, midway between the thyroid cartilage and the upper border of the sternum, through which Dr. D. C. Cocks, without the loss of a teaspoonful of blood in making the opening into the trachea, passed a probe, and therewith located the piece of bone just beyond the glottis. After most patient, painstaking, and persistent effort he dislodged the bone and brought it through the glottis into the mouth, greatly to the delight and satisfaction of us all, thus securing the object we were in search of. Dr. Cocks then introduced a single silver tube, the inner one of the ordinary instruments for that purpose, with instructions to clean it out every few minutes with a feather, and to keep a steam atomizer constantly going.

The child breathed quite easily through the artificial

[1] Read before the Harlem Medical Association, October 22, 1885.

opening for about two hours, when shortly after I had left I was hastily called, the father, who came for me, assuring me I would find the patient dead, and begging me not to blame him to his wife and the bystanders who had collected in the room from other apartments in the same house, because he had removed the tube, though he did so by my directions, for they clamorously asserted that by so doing he had killed the child. It was not dead, however, and on my reapplying the tube and clearing out the collected mucus it breathed easily again.

It was very difficult at first to get attendants at all capable of doing what was necessary for the child. Many times it would be almost choked from accumulated mucus. The father and a friend were soon broken in and made very excellent nurses for that service. It was indeed remarkable how many changes were necessary to enable the child to breathe easy, and yet how some little thing would enable it to do so. When it breathed hard with the tube in, taking it out would make it breathe easy, or when the tube was out, putting it in again would have that effect. Keeping the atomizer at work one time would help it, then to stop it would do so.

The morning after the operation Dr. Cocks removed the tube and stopped the tracheal opening with rubber plaster, through the several layers of which the child breathed some, but also through the larynx. It made a cry quite audible and distinct. In a few hours it became necessary to reinsert the tube, and the instructions were to do so every night. This course was pursued each day for one week after the operation, Dr. Cocks closing every morning the opening in the throat with his fingers for a few moments, and then the adhesive plaster, which he instructed should be left on as long as the patient could bear them, to be removed and reapplied till distress of breathing ensued.

All this time the patient did well, having its hard breathing spells, which would be relieved by such attention as experience had taught was required, but it nursed well and slept for hours very peacefully.

One week after the operation the tube was removed and never reinserted. The child would have difficult breathing at times, but then would breathe easily again; but when the atomizer was kept at work, so as to soften the mucus, and the latter constantly removed, and the already trained nurses (for this case at least) took care of it, the child did well. Unfortunately, the father, who had become most efficient, had to go to his work. As his wife expressed it, "he hadn't a bank account," though some days previously he had gone to the bank to draw money to pay his rent, with the assurance, when he left his wife and sick infant, that he would be gone but one hour and a half, and had returned, after an absence of ten hours, with his sorrows completely drowned in libations with a friend he had met down-town; so that a few moments after his return he was oblivious, in the control of alcohol, of his child's condition, and unable to give his assistance, which was so much needed, to saving his little one's life. For four days after the tube was last removed the patient struggled along, having its ups and downs of breathing, but about ninety hours thereafter died from exhaustion.

There is good reason for the opinion that with sufficient relays of competent nurses the result might have been different, for the father, who had become so capable, was worn out by his all-day work, to which he had returned, and was unable to give attention to his child. The other nurse had to attend to her own children, who were suffering from her absence, and whose own household cares had their imperative demands upon her. We sought to obtain the post-mortem trachea for examination, to see how much closed up it was, but were unable to, owing to the opposition of the mother. I learned from this case the difficulties attending the operation of tracheotomy. The doctor who has charge of it is liable to be summoned at any and all times with the startling assertion that his patient will be dead if he is not there in a few moments, and to be detained altogether many hours of the day in order to give his patient breath to live.

I cannot think, then, for any reason as concerns patient or doctor it should be done, unless, as in this case, it is the only chance for life.

AS TO CARDIAC ASPIRATION.

By W. S. CHEESMAN, M.D.,

AUBURN, N. Y.

The publication of Dr. Westbrook's case of abstraction of blood from the right heart (Medical Record, December 23, 1882) started a discussion to which, so far as I am aware, the most recent contributions in the American journals are an article entitled "Note on a Peculiar Form of Pulmonary Congestion, together with a Plea for Cardiac Aspiration," by A. H. P. Leuf, M.D. (*American Journal of the Medical Sciences*, January, 1885), and the editorial notice in The Medical Record of October 31, 1885, of a case of aortic aspiration by Mr. Dacre. By the former the safety of the procedure is vehemently urged; in the latter it is stated that "experience, so far, shows that cardicentesis is not dangerous."

In a brief communication concerning Dr. Westbrook's case (Medical Record, January 20, 1883), I objected to the procedure on the ground of its peril. Dr. Westbrook found a slight hæmopericardium as the result of his needling, and it seemed to me not hypercritical to ask: "Is there no risk in an operation involving such a contingency? Bearing in mind the tensity of the auricular wall, and the danger that it may tear itself by motion against the needle (not a fanciful danger, by any means), can we consider its puncture as other than a most hazardous expedient?" The same objection was urged by the *Medical News*, February 3, 1883. To both of these protests Dr. Leuf replies (*American Journal of the Medical Sciences*) by denying that the auricle can thus tear itself, because *a priori* the auricular walls are elastic, and *de facto*, because, in the single case reported by Dr. Westbrook, no such tear occurred.

Even had this reasoning been more lucid and convincing, my own apprehensions would not have been quieted, founded as they were upon a case observed while I was an *interne* in Bellevue Hospital in 1880. To justify my position in regard to the danger of cardicentesis, I transcribe the history from my old case-book:

Patient, a woman, aged fifty years. Admitted June 8, 1880, suffering intensely from dyspnœa, which being found to depend on double pleural effusion, was relieved by the aspirator. Further examination revealed the existence of Bright's disease.

The patient was aspirated several times, was finally put on dry diet, and the effusion not returning, was discharged on July 9th.

On July 13th she was re-admitted, suffering horribly from dyspnœa, which was, as usual, relieved by aspiration. Repeated pumpings kept the chest empty. Finally, though both pleuræ were free, she passed into collapse, breathing with great exertion, and almost pulseless. Previous experience with double pleurisies had taught the need of watchfulness for the occurrence of pericarditis, and now for the first time evidences of this complication were found. The area of præcordial dulness was much increased, the apex-beat imperceptible. With the concurrence of another member of the house staff, a hypodermic needle was introduced into the space uncovered by lung, it being hoped that if thereby the diagnosis were confirmed, relief might be obtained by pericardial aspiration. The syringe filled with blood, and was at once withdrawn. While being withdrawn, the needle was distinctly felt to be moved with or against the heart in its contraction.

The patient seemed no worse for this exploration, lived six hours, and died very gradually.

Autopsy.—Head: Brain and membranes œdematous; atheroma of the vessels. Chest: Double pleurisy; considerable exudation of lymph; scanty serous effusion; parenchyma of lungs normal. On slitting open the pericardium its cavity was found filled with clotted blood, which enveloped the heart like a bag. Clearing this away the heart was found hypertrophied, weight sixteen and a half ounces. Left ventricular wall one and a half inch thick. The right ventricular wall was also thickened; but in one spot, between the columnæ carneæ, it happened to be excessively thin, seeming little thicker than the visceral pericardium itself. And just here a rent one-fourth of an inch long was found, allowing of communication between the right ventricle and the pericardial cavity. Heart-walls fatty in places; atheroma of aorta. Abdomen: Liver, spleen, and intestines normal; kidneys very fibrous and small, together weighing only four ounces.

In this case dilatation of the heart had beyond doubt been mistaken for pericardial effusion, and the right ventricle lacerated by the hypodermic needle; and, while before exploration the case was certain to end fatally, it is equally certain that had there been any chance of recovery that chance would have been destroyed.

Subsequent discussion of the case by the house staff elicited the interesting though unpublished fact that precisely the same error, with the same lamentable result, had been made not long before by a distinguished member of the visiting staff, except that in his case the needle had torn the right auricular instead of the right ventricular wall.

With these cases in mind I must beseech the indulgent forbearance of the advocates of cardicentesis, when I confess to being frightened by the three or four ounces of "thin serous fluid of a dark claret color" and clots found in the pericardium in Dr. Westbrook's case, or the two ounces of blood found in Mr. Dacre's. In themselves these are little or nothing. But they mean leakage, hæmopericardium, which in some other case may be sufficiently abundant to kill.

I have before (in the communication above referred to) expressed my conviction that ordinary phlebotomy is far safer and equally efficient. Drs. Westbrook and Leuf deny that bleeding from a vein is an equivalent for cardicentesis. Dr. Leuf actually asserts that this latter is simpler, and requires paraphernalia less disheartening to the patient. But it will probably be difficult to prove these propositions to the satisfaction of a cautious medical public.

One other point has been made much of by Dr. Leuf (in his article above referred to), viz., that the conception of this operation was original with Dr. Westbrook. In this he was probably misled by Dr. Westbrook's own statement (MEDICAL RECORD, December 23, 1882): "About a year ago (*i.e.*, sometime in 1881) *it occurred to me* that in a case of very acute and intense pulmonary congestion, with over-distention of the right side of the heart, it would be practicable" to aspirate the auricle. It is a familiar fact that an ingenious mind may work out for itself by independent research inventions by no means new. Every now and then operations are advocated and credited as novel, till some bibliomaniac arises to show that Hippocrates or Avicenna practised them. I do not question Dr. Westbrook's honesty when he claims to have originated cardiac aspiration, but I cannot see how Dr. Leuf can continue to deceive himself in regard thereto. He himself quotes Roger's cardicentesis, which was performed, I believe, in 1872—ten years before Westbrook's and Hulke's, which also preceded Westbrook's. He examines critically Dr. C. L. Dana's cases[1] (MEDICAL RECORD, February 3, 1883), of which one occurred in 1877, and the other in 1878. In November, 1881, Dr. Corwin (MEDICAL RECORD, March 10, 1883) punctured the right ventricle of a dilated heart, mistaken for a case of hydropericardium, and drew off blood. He farther states that during his house service he "saw and performed cardiac aspiration a number of times."

I hesitate to incur the opprobrium of "opposing original thought by iconoclastic criticism" (Dr. Leuf), but in view of these few facts, which, for aught I know, might be multiplied by farther search, I must ask Dr. Leuf why he terms cardicentesis "Westbrook's operation?" It might also be not improper for Dr. Westbrook to explain why he continues to permit this operation to be so named.

[1] It will interest Dr. Leuf, but probably nobody else, to know that these were the cases of cardiac aspiration alluded to in my communication of January 20, 1883.

ABNORMAL MOBILITY OF THE TONGUE, WITH ABILITY TO PROJECT INTO THE NASO-PHARYNX.

By LOUIS JURIST, M.D.,

LECTURER ON RHINOLOGY AND LARYNGOLOGY, JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

THOS. P——, aged twenty-one, syphilitic, was referred to the Throat Department from the Surgical Dispensary of the Jefferson Medical College Hospital for examination. He had suffered for thirteen years with chronic rhino-pharyngitis, and had been much annoyed by the accumulation and desiccation of mucus in the naso-pharyngeal cavity and on the posterior wall of the pharynx. He often examined his throat with the aid of a hand-glass, and two years ago succeeded, after two months' practice, in reaching his pharynx with the tip of his tongue and removing the masses of secretion. This procedure now became a source of much comfort, and was indulged in daily. On one occasion his tongue slipped into the pharyngeal vault, and gave him still better facilities for cleansing. Upon examination, the evidence of an ordinary inflammation of the turbinated tissues, with hypertrophy and subsequent pharyngitis, was well marked. He could with the greatest ease, and many times in succession, project the tip of his tongue into the vault, and described fairly well the posterior extremities of the inferior turbinated bones, the posterior septum, etc. A probe passed through the inferior meatus was readily and freely moved.

The frænum linguæ was ruptured in three or four places, and he stated that the under surface frequently felt sore, and that he often heard "cracking" while practising. His tongue, rather pointed, was not of unusual length. Nothing abnormal in the conformation of the naso- or oropharynx could be detected. As far as I have been able to discover, but three similar cases are on record. In Dr. G. F. Whitney's case (MEDICAL RECORD, April 28, 1883) the frænum "was merely represented by a lax fold of mucous membrane;" in Dr. Webster's own person (MEDICAL RECORD, May 26, 1883) the frænum had never been cut, but the power acquired with difficulty; in Dr. J. O. Roe's patient (MEDICAL RECORD, June 9, 1883) "the frænum linguæ was well marked, though a little more lax than usual." Dr. E. Fletcher Ingals, of Chicago, informed me by letter that he had seen one case, but furnished no details.

Curiously enough, the faculty has so far been observed only in males!

1210 WALLACE STREET, PHILADELPHIA.

VICARIOUS MENSTRUATION.—Puech, in his collection of over two hundred cases of vicarious menstruation, gathered from different authors, sums up his statistics as follows: Menstruation at roots of hair, 6 cases; by auditory canal, 6; by lachrymal ducts, 10; by nose, 18; by gums, 10; by cheeks, 3; by mouth, 4; by bronchial tubes, 24; from stomach, 32; by the breast, 25; by the axilla, 10; by the umbilicus, 5; by the bladder, 8; by the bowels, 10; by the hands, 7; by the lower limbs, 13; by various regions, 8. In young girls subject to vicarious menstruation the genitals are always moist with a muco-sanguinolent matter at the time of their courses. —*Cincinnati Lancet*, October 3, 1885.

Clinical Department.

PLACENTA TWO MONTHS IN ADVANCE OF FŒTUS.

Dr. Wm. H. Lathrop, of Lowell, Mass., relates a case of miscarriage in which the delivery of the placenta preceded that of the fœtus by two months. The young woman, married, primipara, had been pregnant four months when the placenta was delivered. Two weeks afterward she went to her work in a mill, and so continued till within two days of the delivery of the fœtus. She was conscious of the presence of something in the womb, but it occasioned no inconvenience, and had no odor. She menstruated regularly, and at the second menstruation the fœtus came away. This was March 7, 1885. This occurred in the practice of another physician, and the facts are well authenticated. It was a four-months fœtus, and remained two months in the womb after its death.

INTESTINAL OBSTRUCTION; ACUTE PERITONITIS; OVARIOTOMY; RECOVERY.

Dr. J. W. Lilly, of Pomeroy, O., writes: "On August 12, 1885. was called to see Mrs. B——. married, thirty-four years of age, and the mother of five children. She was suffering from pain in the abdomen, which was enlarged and tympanitic above umbilicus, and dull below and slightly tender on pressure. The bowels were constipated, and symptoms seemed to indicate simply some slight inflammatory bowel trouble; the usual remedies were prescribed, and the patient was apparently better and able to attend to her household duties by August 20th. She said the pain began suddenly while she was lifting her two babies, twins, from the floor.

"On August 22d I was sent for in great haste, and found patient in bed and vomiting. Examination showed the abdomen enlarged considerably, tender on pressure, dull at lower part, and tympanitic above. I diagnosed peritonitis, with some form of tumor in the lower part of the abdominal cavity, and gave minute doses of calomel, ordering an enema of warm soapsuds; these remedies relieved the nausea somewhat.

"The following day the patient was vomiting again, the bowels had not moved, and there was increased pain and tenderness over the whole abdomen. Dr. Relnu was now called in consultation. We decided the trouble was peritonitis, from some form of obstruction of bowel, and ordered an enema of tobacco infusion with milk and absolute rest, and gave one-half grain of morphia hypodermically. This treatment seemed to give relief, as quite a quantity of scybala came away, and the patient then slept for some time.

"However, at night she commenced to vomit again. and toward morning it became stercoraceous. The case was becoming desperate, but I determined to make one more effort to relieve the obstruction, and with this object injected one quart of milk with an ounce of castor-oil and five grains of podophyllum, and gave two drachms of calomel by the mouth. The enema passed away without effect, and the calomel was rejected in a short time.

"On August 25th a consultation was held with Dr. C. R. Reed, and it was decided to operate. The patient, who had by this time gone into a state of collapse with a thready pulse, 160 to the minute, was anæsthetized with the mixture of alcohol, chloroform, and ether.

"The abdomen was washed with carbolized water; then an exploratory incision was made about half-way between pubis and umbilicus in median line. We discovered the intestines intensely congested and much distended with gas; there was general peritonitis, and we found also a new growth extending from the pelvis to within an inch of the umbilicus. The incision was enlarged to six inches, when this body was seen to be an ovarian tumor. Farther examination showed it to be bound down by firm adhesions, one of which caused the intestinal obstruction. The tumor, which was between six and seven inches in diameter, was, after considerable difficulty, torn loose from its attachments.

"Antiseptic precautions were used as far as possible. Before the tumor was opened at all, the abdominal cavity was thoroughly sponged with carbolized water, and I think if this were always done in this operation there would be less danger from the escape of the fluid into the abdominal cavity (as happened in this case), for it would be neutralized by the antiseptic. Not being prepared to operate for the ovarian tumor, we were obliged to do the best we could with the instruments which we had on hand.

"After the attachments were torn loose, it was found that the pedicle was too short to allow the tumor to be lifted out of the abdomen; but, raising it up as far as possible, and holding the abdominal walls against it, we made an incision and inserted an English catheter into the tumor. The fluid was, however, too thick to flow through the catheter, so it was squeezed out into a vessel placed between the patient's legs. When the tumor was thoroughly emptied of its contents, the pedicle was transfixed and tied with aseptic silk, the tumor cut off, and the ligatures left long enough to extend through wound.

"The abdominal toilet was carefully made, intestines returned to place, and the edges of wound brought together with seven deep sutures. An antiseptic dressing was applied and left undisturbed for three days. The patient rallied well and continued to improve steadily until September 2d when a sudden change occurred in the weather and she was taken with capillary bronchitis. There was great depression followed by rise in temperature and pulse. The symptoms were treated as they arose, and in a few days the patient began to improve again, and from this time went on, with only occasional periods of depression, to complete recovery."

GONORRHŒA IN THE YOUNG.

Dr. M. E. Poynter, of Midway, Ky., writes: "The Record for August 15th contains the report of a case, by Dr. Ward, of Greensboro, Ala., concerning a negro boy, seven years of age, having gonorrhœa. The doctor asks if any one had ever seen that disease in one so young. In 1878 or 1879 I had two cases younger, one a boy of three, and a girl five years of age, white, brother and sister. They had a colored nurse, a girl sixteen or seventeen years of age, who was found to have given the disease to the children. It was detected in both the children at about the same time, and I was called to see them, and at once detected the nature of the disease and so announced to the shocked and overwhelmed parents. The girl acknowledged that she had produced erection in the little three-years-old boy by manual manipulation, and then had him *res in re* with herself. Of course she communicated the disease to him, and, by making the little sister submit to the same process of attempted copulation with the boy baby, she was in turn inoculated. Two years afterward the little boy suffered most intensely from stricture, and had to be treated with dilators, etc."

Dr. J. H. Arton, of Winnipeg, sends us the following: "I have much pleasure in beating the record of your correspondent *re* on 'Early Gonorrhœa.' While in Philadelphia, in 1876, during the last weeks of the Centennial Exhibition, I attended a clinic held by the late Professor Gross. One of the cases was that of a boy, four years of age, with a specific urethritis derived from a girl of sixteen or seventeen, who had charge of him. Professor Gross made the diagnosis, and naturally remarked at the time on its uniqueness."

TROUSERS ON THE SPLEEN.

Dr. W. H. Mather, of Suffield, Conn., reports the following remarkable case: On September 29th, W. C——, a farmer thirty years of age, was trying to jump from a scaffold eight feet high, using his pitchfork to aid him in the descent. The fork slipped, however, and the handle struck him squarely between the legs, tearing the scrotum almost completely away and exposing the testicles. In addition to this, the patient complained of excruciating pain in the left side between the crest of the ilium and the ribs, and the tenderness was so exquisite that it was impossible to palpate this spot without an anæsthetic. The scrotal wound was washed with a sublimate solution and the edges approximated by six sutures, and hot compresses were applied to the side. On the fourth day after the injury one pint of pus was discharged from the scrotum. The pain in the side continued in all its original severity, and on the tenth day an opening was made which gave exit to another pint of pus. Ten days later another incision was made and a little more pus evacuated. There was no diminution in the pain, however. On the twenty-fifth day after the receipt of the injury the patient was chloroformed, and a thorough exploration of the side made through the last-formed opening. This resulted in the extraction of a piece of cloth four inches long, one and one-half inches wide at the base, and one-half inch at the apex. It was a triangular piece which had been inserted in the crotch of the patient's trousers, and which would seem to have been pushed up by the fork. There was no appearance of a foreign substance in the scrotum when it was stitched up, nor was there any blood to be seen on the handle of the pitchfork. After the removal of this cloth the pain disappeared, and the patient made a rapid recovery.

UNREDUCED DISLOCATION OF THE FINGER AND OTHER INJURIES.

Dr. James O. Whitney, of Pawtucket, R. I., reports the case of a man who, when in the army near Charleston, in March, 1864, was struck in the abdomen by a falling log and thrown backward, striking his pronated left hand. He sustained a Colles fracture of the wrist and a dislocation of the ring finger at the metacarpo-phalangeal joint, the head of the phalanx being thrown into the palm, where it now remains partly absorbed. The finger is three-eighths of an inch short, and the deformity and disability resulting from the fracture of the wrist are very great. Soon after this accident he discovered that he had a hernia, and this is now very large and practically irreducible. He said also that he was always lame in the right side, and some seven years ago a tumefaction appeared a little outside of the right nipple, pus was discharged, and the cicatrix even now breaks at times and exudes a little watery fluid. Some time later a second abscess formed four inches lower down and was opened. The man had always been strong and robust previous to entering the army, and never received any injury except the one above mentioned, to which it would appear that all his subsequent ills should be referred.

COCAINE AS AN ANÆSTHETIC IN FRACTURE.

Dr. J. R. Conway, Jr., of No. 14 Lexington Avenue, writes: "Having read with great interest Dr. M. Josiah Roberts' recent article on the use of cocaine in bone surgery, it occurred to me that it would be equally applicable for the painless examination and reduction of fractures. The first case in which I had an opportunity to use it was that of a painter, who had fallen a distance of thirty feet to the ground, striking upon his right buttock and the palmar surface of the right hand. The right radius was fractured about three-fourths of an inch from the lower extremity of the bone, and the lower fragment was displaced backward upon the upper one and firmly held in that position. All attempts at examination of the fracture caused him great agony, and I resolved to try if deep injections of cocaine at the point of fracture would sufficiently anæsthetize the parts to allow of thorough examination and reduction of the deformity without causing him pain. I proceeded to inject five minims of the four per cent. solution into the inner, outer, and posterior surfaces of the forearm directly over the seat of fracture and as deep as the bone. In five minutes the fracture could be thoroughly examined and even roughly handled without the patient experiencing the slightest pain. After the examination I reduced the deformity by extreme extension of the wrist-joint together with traction, using considerable force, but without causing the patient any uncomfortable sensations."

Progress of Medical Science.

Resorcine in the Treatment of Diarrhœa.—In septic diarrhœa, either acute or chronic, characterized by dejections of a fetid odor, and by the presence in the fœcal matters of a large number of micro-organisms, M. Bogouche has obtained excellent results with resorcine dissolved in castor-oil (*Journal de Médecine de Bruxelles*, September, 1885). When thus prepared, the resorcine never causes ringing in the ears, profuse sweats, or other unpleasant symptoms sometimes noted when the drug is given alone, a difference in action which the author explains by the more gradual absorption of the oily solution. For an adult the author gives fifteen grains of resorcine dissolved in about five ounces of warmed castor-oil. To children of about four years of age he gives from three-fourths to one grain in a corresponding quantity of oil. M. Bogouche has met with so great a measure of success in the treatment of fetid diarrhœa by this method that he is encouraged to hope much from it in cholera. In this disease he recommends a mixture of salicylic acid and resorcine dissolved in castor-oil. The dose given by the author, one gramme of resorcine to one hundred and fifty grammes of castor-oil, seems rather excessive, and is probably intended, though it is not so stated, to be given in divided doses during the day.

Thomsen's Disease.—The two following cases of Thomsen's disease are reported by Professor Bernhardt, in the *Centralblatt für Nervenheilkunde*, No. 6, 1885. The patients, brother and sister, aged respectively sixteen and a half and eighteen years, say that the disease began in the lower extremities at the age of four or five years. In the case of the boy it has spread to other muscles, but the sister has retained fairly normal power of movement of the upper extremities. After a good night's rest she does not feel stiff, can leave her bed without difficulty, but on moving about much she experiences the characteristic symptoms of the disease. After sitting quietly for some time she becomes stiff the moment she again stands, and would fall if touched even lightly. The first few steps taken are stiff and awkward. Close attention paid by her to her movements and the exercise of an effort of will result in a partial control of the stiffness and render locomotion less difficult. Her other muscles are all well developed. The brother, a strong man, with athletic development of muscles of arms and legs, shows the typical symptoms of the disease. The parents of these patients were cousins, as were also the grandparents. One of the father's sisters was similarly affected; another sister married a cousin, and both of the children resulting from this marriage have the disease. Farther, the son has married a cousin, and their child, a boy of four or five years, now shows the first symptoms of the disease. Professor Erb, of Heidelberg (*Neur. Centralblatt*, No. 13, 1885), says: "Clinical observation of the motor nervous systems and muscles of three brothers, aged about four-

teen or fifteen years, who were affected with this disease, have shown that we have in reality to do with an abnormality in the form of the contraction of the muscles, and the prolonged latent period and the continuance of the contraction are characteristic. This 'myotonic contraction' can be overcome by *direct* action on the muscles (mechanical, faradic, or galvanic irritation), or through the nervous system, only when a series of rapidly accumulating irritants, such as voluntary action, secondary faradic currents, or liable galvanic current, act on the nerves." He designates under the name "myotonic electric reaction" the changes in electric excitability, which, in a characteristic way, differentiate this condition from that of degeneration, of tetany, of muscular hypertrophy, etc. The examination of a piece of muscle excised from the biceps showed considerable hypertrophy. The diameter of the muscular fibre varied from 24 to 180 μ (normal 25 to 65 μ). More than 50 per cent. of the fibres were from 80 to 140 μ in breadth, while only 2 per cent. were under 40 μ, and 8 per cent. were over 140 μ. On measuring, for purposes of comparison, the biceps of a patient in good condition, who had died of an acute disease, the extreme limits of breadth were 12 and 80 μ, 62 per cent. between 20 and 60 μ, 7.5 per cent. under 20 μ, and no fibres above 80 μ. The fibres are of more rounded form, the angles being rounded off, and they are not pressed together in polygonal forms, as in the case of normal muscle. Erb also found that the nuclei of the sarcolemma were much increased in number, viz., 65, as compared with 18. The transverse striæ were very fine, often somewhat indistinct. The author expressly warns against attaching too much value, at any rate prematurely, to the above abnormalities as supporting a theory of a myopathic origin of the disease.

Dentist's Leg.—A peculiar sensation of numbness, or "pins and needles," in the extremities is frequently experienced by dentists. This condition Dr. George Johnson considers to be due to the combined influence of perverted nerve-function, directly due to a mechanical impediment to the circulation through the rigidly contracted muscles and their associated nerves, and to direct compression of the nerves by the firmly contracted muscles. This combination is found in dentists who stand fixed and firm in one position for long periods of time. The obvious means of prevention and of cure consist in rest for the overstrained limb, or such a frequent change of position as is equivalent to a certain amount of rest. Standing in one position is notoriously more fatiguing than walking, and for the obvious reason that while in standing one set of muscles is in a constant state of active contraction, the circulation through them being thereby retarded and enfeebled, walking involves alternate contraction and relaxation of the muscles, with an invigorated and quickened circulation.—*The Lancet.*

Local Asphyxia and Symmetrical Gangrene of the Extremities.—It will be remembered that Verneuil and Petit have recently given considerable attention to the peculiar condition of local asphyxia of the extremities and symmetrical gangrene. Their belief that paludal poisoning and consequent cachexia play an important rôle in the etiology of the affection appears to be borne out by other cases recently reported. Dr. Giovani (*Giorn. Ital. delle Malatt. Ven. e Cut.*) has had under his observation a patient who, after having lost five brothers and sisters from some unknown disease, remained well himself until the age of twenty-five. At that time he appears to have acquired syphilis. Pains in the bones persisting after the other symptoms had disappeared, he applied for treatment at the venereal clinic, and was given vapor baths and mercurial frictions. Somewhat later the patient had an attack of paludal fever, and was only cured after six months' treatment with sulphate of quinine. Following this came circulatory troubles; he began to experience, among other things, an unaccustomed sensation of coldness over the phalanges of some of the fingers. The sensibility of the hand became blunted. The same conditions were noted by the patient in regard to the toes. Violent pains, increased by pressure, now made their appearance. The color of the integuments affected was modified. The parts which were at first pale became of a dark red color. Flexion and extension were impeded; the epidermis was thickened and wrinkled over the index of the left hand, and gradually became detached in large flakes, whereupon the pain ceased in this finger. Suppuration began about the nail of the right index finger; the pus burrowed to the exterior through the epidermis of the pulp of the finger. Professor Gamberini made the diagnosis of symmetrical gangrene of reflex origin. After several months of symptomatic treatment cicatrization was complete, but some torpor remained in the extremity of the fingers. Bouveret published, in the *Lyon Médical*, June 8, 1884, the following case: "The patient, a woman aged sixty-eight, resides in a country where ague is endemic, and has suffered repeatedly from it. She has also had atheroma of the arteries. In January, 1883, the middle finger of the right hand became cold and of a dark color. Some time later the other fingers of the same hand were similarly affected. The disease gradually progressed until all the fingers and toes, as well as the palms and backs of the hands, became at times cold and blue. Purple patches appear now and then on the forearms. There is diminished sensibility of the affected parts, and at times sensation appears quite abolished. Dipping the extremities into warm water causes a temporary disappearance of the symptoms." It appears probable that in this case, as well as in that of Dr. Giovani, the malarial fever which preceded the local manifestations was an etiological factor. The subject is an interesting one, and undoubtedly many cases similar to those here given could be made clear by the discovery of this malarial origin.

Effects of Zymotic Diseases on the Teeth.—In the *Independent Practitioner* for September, 1885, Dr. F. S. Whitslar thus concludes a paper on this subject: "Now, what are the effects of zymotic diseases upon teeth which bear none of the marks of partial development? We answer, that all febrile conditions or diseases predispose teeth to decay, first, by diminishing vitality, second, by changing the secretions of the mouth so that they act injuriously upon the teeth. In dyspepsia we have not only the predisposing but also the exciting causes of decay, as it not only impairs vitality but prepares in the stomach an acid that is continually being thrown upon the teeth, which acts upon them with great energy. I need scarcely say that residence for any great length of time in miasmatic regions, inducing unfavorable conditions, institutes a predisposing cause, and, in brief, all epidemic, endemic, dietetic, and enthetic diseases derange the functions of the body, vitiate the secretions, impair the vitality, and may be classed as predisposing causes of decay."

Scalded Oatmeal in the After-treatment of Scarlet Fever.—Dr. George Smith, in the *Bristol Medico-Chirurgical Journal*, treats of the subject of the desquamation which follows every case of scarlet fever, however slight, both in regard to its bearings on the patient himself, and also those with whom many cast-off particles may come into contact. The process of desquamation varies very much in different individuals, and sometimes it is done by particles so fine as to be hardly perceptible. And these are, he thinks, a very frequent and most certain source of contagion, by means of clothes and otherwise; much more so, indeed, than the scales as ordinarily thrown off. It is within his own knowledge that the contagion has been thus carried from one house to another, more than a hundred miles apart, at the end of at least a year from the attack. Now, to obviate this danger, he has for several years been in the habit of

having his patients sponged over the whole surface of their bodies twice a day—commencing, as a rule, about a week from the appearance of the eruption, and continuing the process until the desquamation is complete—with a mixture of one ounce of oatmeal to one pint of boiling water; the solution is to be made fresh every day, and used tepid, or at such a temperature as may be comfortably borne by the back of a finger. His reason for using this particular combination is, that the gluten in it sticks the scales to each other and to the surface of the body, thus allowing of their being removed from one sponging to another, without the ordinary risk of infecting either atmosphere or clothes, and greatly lessening the risk of spreading the disease. Secondly, this same gluten fills up the cracks of the new skin and protects it from cold, as, patch after patch, it becomes bare, and thus, to say the least, greatly lessens the risk of the dropsy which so often follows upon this disease.

A New Physical Sign of Tricuspid Regurgitation.—Dr. W. Pasteur, of the Middlesex Hospital, London, writes as follows: "In several cases in which there was reason to suspect functional incompetence of the tricuspid valve which have recently come under my observation, a physical sign has been present to which I believe attention has not been drawn, and of which I have been unable to find any mention either in the standard text-books or in the best known monographs on the subject of cardiac disease. This sign consists in a distention—with or without pulsation—of the superficial veins of the neck, occurring when firm pressure is exerted over the liver in the direction of the spinal column, and independent of the movements of respiration. A little consideration of the anatomical relations of the parts concerned will suggest the facility with which an impediment may be created to the flow of blood, in either direction, through the vena cava inferior by such a manœuvre, especially when the liver is obviously enlarged. It seems to me that the state thus produced is virtually that which obtains as a chronic condition in long-standing and severe cases of tricuspid incompetence as far as regards the tension in the systemic venous system in the immediate vicinity of the heart. Assuming the existence of tricuspid regurgitation and of a source of compression of the vena cava inferior, it is obvious that with each systole an excessive reflux of blood must take place into the vena cava superior and its tributary veins. It may be noted that the question of pulsation, as compared with distention or undulation, is merely one of degree of morbid venous tension. Although the number of cases in which I have observed this phenomenon is certainly limited, I have never failed to elicit it when there was indubitable evidence of tricuspid incompetence; on the other hand, I have hitherto invariably failed to obtain it in other forms of cardiac valvular disease, and in various cases of hepatic enlargement from causes other than passive congestion. I cannot but think that this sign may furnish an important aid to diagnosis in cases where the usual signs of tricuspid regurgitation are ill-developed or in abeyance, and that it may prove a valuable factor in the difficult general problem of prognosis in cases of cardiac disease."—*The Lancet.*

Foreign Bodies in the Urethra.—A great variety of objects have been found at different times in the male urethra requiring surgical procedure for their removal. Among the more common articles intentionally or accidentally lodged in the canal may be mentioned pieces of wood, bits of straw, pipe-stems, pencils, pins, needles, and hair-pins. Pearls, medals, and other curious objects have occasionally been met with. The surgeon is at times called upon to extract the broken end of a catheter, or to remove fragments of calculi. In July last a patient entered the Charité Hospital, in Paris, who had introduced a birch-stem into his urethra three days before, which had broken, leaving a piece nearly two inches in length in the canal. To recover the missing portion he had improvised an instrument from a similar stick, in the end of which he had fastened a bent pin. With this primitive instrument he made diligent search along the canal, but, to his amazement and disgust, he found upon its withdrawal that not only had he failed to catch the stem, but that his hook was gone. Examination with the sound showed the pin to be lodged in the bulbous portion of the urethra. Farther exploration was not attempted. To calm the patient's excitement and overcome the sympathetic vomiting which existed, he was put at rest and given a daily hot bath for three days. He was then placed in the lithotomy position, chloroform was given, and Dr. Després performed external urethrotomy at the point opposite the implanted pin. The index finger was introduced, the pin found, and extracted with forceps. The lithotrity forceps were now introduced through the perineal opening into the bladder, as the wood had not been found in the urethra. All attempts to find the object of the search were in vain. It was presumed that it had been softened, and gave the same sensation, when grasped between the blades of the instrument, as the mucous lining of the bladder. The wound had healed at the date of writing, leaving a fistulous opening through which urine had ceased to flow. It was expected that the wood would soften, and be passed in small pieces with the urine, or would become the nucleus of a calculus. In the latter event Dr. Després proposes to perform a lithotrity, such as he describes (*Gazette des Hôpitaux*, 1879, p. 41) in a case where a piece of a sound had broken off in the bladder and become incrusted.—*Gazette des Hôpitaux*, October 1, 1885.

Iodide of Potassium in Habitual Abortion.—M. Goshkevich says that, though it is usually believed that iodide of potassium tends to produce abortion, and its use is, therefore, generally avoided in pregnancy, he advises that it should be given in cases of habitual abortion. The causes of this are obscure, but the best known of them is undoubtedly syphilis. With this in view, he prescribes the iodide even when no syphilitic symptoms have been recognized, and gives two cases to prove the advantage of this. The heart-sounds and movements of the fœtus, both of which had become almost imperceptible, improved under five grains three times a day, and diminished whenever the medicine was stopped. In each case the normal period was completed, though previously both the patients had been accustomed to miscarry during the second half of pregnancy.—*The Lancet.*

Cocaine in Litholapaxy.—Professor Bruns reports a case in which he obtained local anæsthesia of the bladder and urethra by injecting a cocaine solution, with the most gratifying result. The patient, a young man, had suffered for four years from stone in the bladder. Chronic cystitis was present, and evening feverishness. The injection of one gramme (mostly into the bladder itself, in a two per cent. solution, but also a little into the urethra) produced complete local anæsthesia for half an hour, during which time a very hard oxalate of lime calculus was thoroughly crushed, and removed without pain. After the injection, the patient assumed a different position, to bring the fluid into contact with the whole inside of the bladder; and after the operation, a little of a ten per cent. of iodoform-glycerine emulsion was injected. The recovery was uninterrupted.—*British Medical Journal.*

A New Styptic.—The Berlin correspondent of *The Lancet* writes that some time ago a French physician, Dr. Mennier, reported that a priest, who frequently suffered from bleeding at the nose, having been attacked by a fit of such hemorrhage lasting for nine hours, had, after trying unavailingly all possible remedies, at last stopped it by drinking an infusion of the common nettle, urtica dioica. Thereupon Dr. Rothe made some experiments with the external application of the juice of the said plant. Young plants gathered in spring were cut up (stalks, leaves, and blossoms), macerated for a week in

alcohol of sixty per cent., pressed out, and filtered. It was then a dark greenish-brown fluid of aromatic smell and taste. Applied by means of cotton-wool to bleeding wounds, it promptly arrested hemorrhage, unless large vessels were affected, especially parenchymatous bleedings and those from smaller blood-vessels. The blood was converted into a soft, consistent, but not crumbling clot, which seemingly protruded into the opening of the wounded vessels, thus arresting hemorrhage. In cases of bleeding from the nose, a small cotton plug steeped in the liquid is pushed up the nostril high enough to come into close contact with the bleeding surface, and then, if necessary, fixed by means of a dry plug. Should the hemorrhage cease immediately, the plug may be cautiously moved after the lapse of about ten minutes. If some blood oozes out through the plug, it will have to be replaced by a fresh one. In several hundred cases thus treated the bleeding was always arrested within half an hour at the very latest. Quite striking was the effect in the case of a young man bleeding from the lower jaw, after extraction of a molar; for the hemorrhage had lasted for three days incessantly, in spite of compression and the application of external and internal styptics. For years Dr. Rothe has used this "liquor hæmostaticus" in all operations with predominantly parenchymatous hemorrhage, as in herniotomy, tracheotomy, smaller amputations, splitting of the cervix uteri, etc., in the same way as the solution of sesquichloride of iron was formerly employed, but with the great advantage that the blood-clots did not so easily crumble and decompose. The nettle solution has, on the contrary, on account of its alcoholic component, antiseptic qualities; and it is especially indicated in simple cuts of the skin not requiring suture; for not only will the bleeding promptly cease, but by the application of cotton-wool steeped in this solution the wound will speedily heal. The superiority of this new styptic is, above all, evident in non-puerperal hemorrhage from the mucous membrane of the uterus. If, as is generally the rule in cases of mucous polypus and endometritis hemorrhagica, the orifice of the uterus is sufficiently wide open, an injection of from five to ten grammes of the liquor, after previous cleansing with a cold or warm solution of carbolic acid, will produce a permanent stopping of the hemorrhage, except where the mucous membrane is too much degenerated. Should the removal of an excrescence by operation or scraping (with the blunt curette) become necessary, the wound can be cleansed with a warm solution of carbolic acid, whereupon a plug of cotton-wool steeped in the nettle infusion, with subsequent injection of the same, will, in nearly every case, produce the speedy cessation of the hemorrhage.

The Treatment of Patients Affected with Disease of the Prostate.—In a communication to the *Annales des Maladies des Organes Genito-urinaires*, Dr. Guyon formulates the following rules of treatment for the affection: 1. The avoidance of all causes of general or local chill. 2. The proscription of over-eating and alcoholic excess, and in general avoidance of abuse, rather than the simple use of salads, meats, fish, shell-fish, white wines, and champagne. Not only should excess of irritating or alcoholic drinks be avoided, but also that of beverages in themselves inoffensive. For this reason the treatment of the affection by mineral waters should be advised with extreme caution. 3. Voluntary and prolonged retention of the urine should be avoided, as being conducive, in those affected with prostatic disease, to the production of retention, cystitis, etc. 4. Moderate indulgence in sexual intercourse. 5. Consideration of the unfavorable influence exerted by prolonged horizontal decubitus and immobilization. Prolonged rest in bed should be avoided, and before retiring, the patient, if possible, should, if unable to walk in the open air, promenade in his room for fifteen or twenty minutes, and in the morning such exercise should be repeated. During the day sedentary habits should not be contracted, but at the same time fatigue should be avoided. Constipation should be obviated, if existing, without the use of drastic cathartics. A large enema, warm or cold, in the morning exercises at the same time an evacuating and a soothing effect. Emollient enemata, before retiring, frequently also yield good results. 6. The function of the skin should be excited by dry friction and massage. Baths should not be continued beyond fifteen minutes. Regarding the medicinal treatment of the affection, Dr. Guyon suggests: 1. As a remedy for the sclerosis of the urinary apparatus, the use of potassium iodide in quantity varying from eight to fifteen grains daily, during fifteen days or three weeks of every month, and continued for months or years. 2. For the congestive lesion, the careful administration of ergot, nux vomica, and all preparations containing strychnia as a base, is advised. 3. As remedies for vesical irritation, belladonna, hyocyamus, and the preparations of valerian will be found more offensive than opium and its derivatives, but nevertheless sufficiently active. The bromides are considered to have in vesical disease only an insignificant effect, but in some cases this should be utilized. The foregoing hygienic and medicinal treatment, Dr. Guyon considers, will, in most instances, suffice to overcome the functional disturbances experienced by prostatics, and only when it fails should the use of the catheter be resorted to.

Progressive Locomotor Hemiataxia.—Neurologists are acquainted with cases of locomotor ataxy that have symptoms only on one side of the body. Apparently such cases are not of frequent occurrence, but we certainly require more definite information on the earlier stages of tabes dorsalis before a positive opinion can be pronounced on this question. M. Bertoye has placed on record a case of the kind. The patient was a man, aged forty-eight, a weaver by occupation. The previous history gave no evidence of venereal excesses, syphilis, alcoholism, saturnism, or rheumatism. When twenty-eight years of age, "lightning" pains were first experienced. Five years ago, almost suddenly, he was attacked with plantar anæsthesia and inco-ordination of movements of the right leg, which had alone been the seat of pain. A little later the right arm was affected. There was no loss of power and no muscular atrophy. The inco-ordination was evidently due to the want of proper guiding sensations; for with the eyes shut the patient was unaware of the position of the right hand and foot. From a consideration of the literature of tabes dorsalis, and from his own experience, M. Bertoye draws the following conclusions: 1. Progressive locomotor ataxy is often produced as the result of muscular, genital, and other forms of *fatigue*. 2. When this is the mode of production, the disease has a special tendency to affect the overworked part or parts. A corollary is drawn to the effect that certain occupations entailing exaggerated employment of certain functions may determine tabes dorsalis with localization of symptoms in the overworked organ. Lastly, it is argued that if the occupation demands simultaneous over-action of an arm and leg on the same side of the body, the tabes will assume the hemiataxic type. The condition of the knee-jerk is of great importance in cases of genuine hemiataxia, for it disappears on the diseased side and is retained on the sound side.—*The Lancet*, October 3, 1885.

The Opium Habit.—Dr. J. B. Mattison, of Brooklyn, writes: "One error in your review of my monograph on the treatment of opium addiction should be corrected. In treating the diarrhœa, thirty-minim doses of fld. ext. coto (not coca) are commended. This need, however, seldom arises, not having had a case this year in which an astringent was demanded. Your reviewer asserts: 'The author makes the cure of this "toxic neurosis" appear not very feasible.' Such an impression was quite apart from my purpose."

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, November 14, 1885.

MODERN THERAPEUTICS.

THE subject of materia medica, considered as one of the seven principal branches of medical instruction, is not an attractive one to the average student. After he has gone over the introduction, learned how to write prescriptions, and plunged into the study of the remedies themselves, he finds himself in a desert where the oases are few and far between. The multiplicity of detail bewilders him. The conflicting opinions of various authorities concerning the physiological action of drugs, leave his mind in doubt. The large number of remedies which he is told in advance are useless, and yet whose preparations and doses he is compelled to learn, complete his disgust. He learns them for examination and then they are forever buried. In short, much valuable time is wasted on what has no practical value.

It is a common remark that the older a man grows the fewer remedies he uses. This does not necessarily arise from a growing distrust in the power of remedies, nor from a cessation of progress in the line of professional acquirement. It is rather because the limitations of the therapeutic effects of drugs become better understood, and the physician learns how to cover more, so to speak, with combinations of the old orthodox remedies. His whole system of therapeutics has grown simpler. There was much sense in the somewhat homely remark of an old practitioner who declared his need of only four remedies, "a heater, a cooler, an opener, and a shutter." This practice has undoubtedly led to the abuse of certain remedies, and made even their names a terror to some people, who have come to regard them as rank poisons. Mercury is a notable illustration. The system was often uselessly saturated with it. The bones were veritable quicksilver mines; yet who to-day denies the wide range of the power of calomel when properly used? The abuse, and not the use, threw medicines into discredit.

There are at the present time two extreme schools of therapeutists. One pins its faith almost entirely upon medicines, though by no means ignoring the good effects of nursing, food, and general hygienic environment; the other has very little faith in drugs outside the specifics, like quinine, mercury, and opium. It relies mostly on food, nursing, and proper surroundings. Its general plan of treatment is to keep the patient comfortable and to trust to the *vis medicatrix naturæ*. This latter plan is not so fatalistic as it may seem. We should, whenever possible, relieve the distressing symptoms of any malady, but until we understand its pathology, we are not in a position to resort with any success to specific medication; hence, the general tendency, as one becomes better acquainted with disease processes, to a diminution of faith in much of the current methods of prescription and to an increasing belief in the reparative or destructive powers of nature, on which we can exert very little influence. This plan, however, does not always yield satisfactory results. An enlargement of our knowledge of pathology has not been followed by a corresponding increase in our ability to cure disease. We are obliged to hold our ideas of treatment in solution, so to speak, and their crystallization must be determined by our increase of positive knowledge. The plan of treating symptoms will be apt to make chemical laboratories of our patients' stomachs, *unless* we bear in mind the actual condition and make our remedies all work toward one end.

The indications for treatment are comparatively few in any one given case. The less we understand it, the more numerous are the vaunted "specifics" for its cure. In a list of thirty remedies at the outside, we can find in ninety-nine cases out of every hundred means wherewith to give our therapeutic skill its fullest scope. The manufacturing druggist, however, gives us new remedies and new preparations of old remedies *ad infinitum*, and we might add *ad nauseam*. Testimonials follow in quick succession, and it requires some firmness to escape being turned aside from orthodox paths. The action of remedies can be taught, it is true, in didactic lectures, but bedside experience alone can galvanize this inert mass of mental acquirement into life. Then only can a man feel any confidence in the action of remedies, whatever may be his "persuasion" concerning their ultimate good.

THE GUARDIANSHIP OF OUR BORDERS.

Now that small-pox has prevailed at Montreal for some six months, very active measures are being taken to prevent its being brought over the border. The National Quarantine Act of 1878, by which Congress conferred authority upon the Executive to prevent the introduction of contagious diseases, has been revived, and its enforcement placed in the hands of the Marine Hospital Service. This Service has established an inspection system along the Canadian border in those States in which local boards are not doing the work. We learn that the States of Michigan and New Hampshire are the only ones that attend to these inspections independently. The others co-operate more or less with the Marine Hospital Service. Meanwhile the National Board of Health has to sit still and look on.

The matter of the protection of our borders against the introduction of infectious diseases appears to be in a decidedly anomalous condition.

AN ENGLISHMAN'S VIEWS OF AMERICAN MEDICINE.

AN English physician, practising in Sacramento, Cal., writes a letter to the *British Medical Journal*, in which he defends the American Medical Association and its action in connection with the Washington Congress, by baptizing the whole American medical profession in mud.

The method is somewhat as follows: After delineating in glowing colors the perfect loveliness of British medicine, he says:

"Turning from this aspect of the question, it is with feelings of sadness and disgust that I view our own. A vast area of country, in parts but sparsely settled; outlying districts, with uncertain and difficult communication. No National law; a State law, in four or five instances; a host of irregulars, impostors, and charlatans, in every depth of ignorance and iniquity. These laws regulating the practice of medicine are often harmful, and always difficult to enforce. Convictions are hard to obtain, and when trials are had before a jury, the law is a dead letter.

"There are numerous 'schools' and 'colleges,' the majority of which have the power of granting diplomas. The requirements of some of these bodies are very low, and, as a consequence, results obtained are inferior. The social standing of the profession is *nil*, that of any 'other kind of doctor' is just as good. It has no distinctive position. The people understand that there are three 'schools' of medicine—the Allopathic, the Homœopathic, and the Eclectic.

"Such is the standing they have acquired that, in some States, mixed boards of health have been appointed, comprised of 'representatives' from the 'different schools of medicine.' There is no civilized country in the world where empiricism has such latitude and scope, none where intelligent people will allow themselves to be so easily duped."

It is not a pleasant thing to find American medicine pictured in this *ex parte* manner to the whole British medical public; nor was it, we venture to add, either necessary or in very good taste to make such disadvantageous comparisons simply for the purpose of helping an Association of which the writer confessedly knows but little.

Much as we dislike to bring up such issues, or to appear in the rôle of an apologist, justice compels us to utter some protest against the Anglo-Sacramentese view of the state of medicine in this country.

We would suggest, first of all, that our country is not quite such a lonesome and sparsely settled tract as is intimated. The centre of population is not a day's trip from New York. Out of our sixty thousand physicians one-half practise in our Atlantic seaboard States, while all live in accessible localities and are in regular communication with the outside world. When we add that the majority read THE MEDICAL RECORD, and often visit the metropolis, enough on this point has been said.

Our medical laws are not uniform, it is true, and, like the British laws, are not perfect. But, so far from their being "a State law in only four or five instances," twenty-nine or more of our States have laws regulating medical practice. According to Dr. R. J. Dunglison, these laws are working satisfactorily in a large number of States, while everywhere they are progressing toward unity and efficiency. We have numerous cheap colleges, we must admit, but we also have some of the best didactic institutions in the world, and it is from these that the great majority of students graduate.

No spectacle can be more curious than that of an English physician deploring the social standing of American practitioners. Socially, the position of the American physician is a good one; it is indeed whatever the individual desires to make it. Medicine does not handicap, but rather helps him. The American physician is better paid and lives far better, probably, than the average European practitioner. Best of all, perhaps, he is unhampered by traditions and usages that limit his progress or obstruct his ambitions. No inflexible rules assign his social position, limit his future, and dampen his energies. This freedom for endeavor and largeness of opportunity is a thing which gives to American medicine, despite all its failings, a character that has lifted it to equality with any in the world. The daring, ingenuity, therapeutical aptitude, and progressiveness of American physicians and surgeons are recognized, despite some non-uniformity in our medical laws; and, by virtue of these qualities, we have contributed as much as our well-regulated cousins across the water to gynecology, otology, orthopedics, dermatology, and perhaps some other departments of medicine. We are not, in fact, quite such a lawless and quack-ridden body of men as is intimated at Sacramento.

The English correspondent referred to has given, we fear, a somewhat rose-colored view of the state of English medicine, in his desire to have a good background for setting off our American deficiencies. Will he pardon us for intimating a doubt whether quackery is entirely eliminated from Great Britain, the home of anti-vaccination, anti-vivisection, the Salvation Army, the *Pall Mall Gazette*, and Holloway's pills. Is education in such an admirable state when it has nineteen licensing boards of variable standards, and when it allows the largest city in the world to become the poorest educational centre in Europe. We admit that the social position of the English physician is rigidly and perhaps suitably fixed, a little above the head-butler and a little below the curate; but we can hardly see why this is claimed as an advantage; nor, in the light of the social success of such men as Sir Oscar Clayton and Dr. Kidd, do we see how the English correspondent can deny any social standing to English "irregulars."

As for the American Medical Association, the whole profession has at one time wished it well, and hoped much from it. But what actual good is it doing? Has it helped a single educational reform, lessened quackery, amended, unified, or helped the enactment of medical laws? Decidedly not. That it has done good in the past, in stimulating medical organization and promoting the solidarity of regular medicine, we gladly admit. It is because it has ceased this work and has broken and divided the profession that it meets opposition and criticism now.

We should like to see a national medical body, wisely regulated and animated by broad and unselfish purposes; but the American Medical Association does not now furnish the picture.

THE ECLECTICS.

WE believe that most physicians have very vague ideas as to what the so-called "Eclectic" really is. Perhaps the eclectic himself has been at times a little mixed as to his intellectual and medical status.

"Eclecticism" in medicine, whatever it once was, seems now to be losing its distinctive character as a

school having a peculiar therapeutic practice, and to be becoming simply a watchword for those who desire the greatest possible freedom from restrictions, legal and social, on the practice of medicine. The Eclectic Medical Society of this State has declared formally against all attempts at placing legal restrictions on the practice of medicine, and the President of the Eclectic Medical Association of Pennsylvania declared, in his annual address, that the principles of eclecticism are based mainly on "the American principle of freedom." Eclectic medical journals raise the same cry against all legal or social restrictions to the free practice of medicine by everybody on everybody.

All this might be very well if the principles were carried out with an honest regard for the welfare of the profession and the State. But in practice "eclecticism" is in the main an attempt to justify medical diploma-mills and cheap colleges, and to organize and give respectability to quackery and quackish practices. The creed is: "Let anyone practise who wishes to do so; let him get his diploma as he wishes, and let him help his practice with as much advertising as he desires."

Such a "school" may do some mischief for a time; and it is shameful that it can attract even as much attention as it does, but it never will succeed in establishing a position or winning the respect of society.

The practice of medical advertising is bound to increase, in a measure, in this country, but the nature of medical services is such that it never can or will be indulged in by the vast majority of competent practitioners.

As for diploma-mills, in every succeeding decade a thorough and sound medical education will tell more with the people, and the ignorant charlatan will have to skulk more and more in the by-ways. The annual vaporings of "eclecticism" are like the disagreeable miasms that arise from broken and half-cultivated ground—as the country settles they disappear.

THE MAMMARY GLAND IN ART.

In a large number of treatises on physiology, even of the most advanced character, the statement is made that the function of the human mammary gland is the secretion of milk. We are obliged to take the opportunity of announcing that this is a mistake, and only goes to show how blind the scientific mind often becomes to the evidences of serious progress in the world about it. We admit, to be sure, that the mammary glands of women can and do sometimes secrete milk for limited periods of time, and in a gentle and apologetic manner; but all this has become quite a secondary matter, as wide-awake observers of human progress well know.

There can be no doubt whatever that the true and essential function of these glands at the present day is ornamental and æsthetic. Their noblest opportunities are not in the "milky way," but in the line of high art and realistic delineation. They are functionally at their best when they are being painted in strong lights and shadows, photographed by a patent process and exhibited in our shop windows for the education of the masses. The mamma belong to art, not infancy, and the modern painter needs only a bust of recent post-partum proportions in order to be caught up at once by the whirlwind of success.

This is, in fact, the glandular era in art; a time when a walk through our picture-galleries is one long "bust.' This era began somewhat sharply in Paris, eighteen months ago, when a picture was exhibited of two women naked to the waist, fighting a duel. There were some indistinct suggestions of a background, a foreground, and certain other conventional accessories, but the main features were two sets of mammary glands, and to all appearances, it was these interesting lacteal organs that were having the protuberant controversy. From that time there has been a steady influx of contributions to mammary art, and it has now got a fixed and inflexible hold upon the public.

We wish to treat what is plainly a delicate subject in a scientific and purely inoffensive manner. We have ventured upon it with some diffidence, and only because we feel it to be a matter of real importance to the physician to learn that the human mamma has been merely undergoing a certain change of function and rise in æsthetic importance. And we have not presented all the evidence of these facts. It is well known that a very large industry has been established for the manufacture of infant foods. These foods are doing, with the help of the cow, what the mammary gland once did. The manufacture of infant foods supports a large number of people, adds diversity to our industries, and provides an additional means for the accumulation of wealth. It has been a fundamental principle in our political economy that the State should support and protect its infant industries, of which the manufacture of these foods is surely the purest type.

No wonder, therefore, that they have thrived, and opportunely supplemented the needs of the artist world.

Both the demands of art and the dictates of sound political economy, therefore, require that the lacteal glands, as such, should go. We have every reason to believe that in the higher and municipal types of civilization they have already gone.

Withdrawn from the soulless gaze and sharp erosive grasp of the infant these glands are now appearing in unimpoverished splendor on the canvas of the artist, the sensitive plates of the photographer, from which points they furnish, doubtless, a subtle delectation to appreciative adults.

Here is, apparently, the illustration of a splendid evolutionary and physiological triumph: that what was once, in some pre-*ornithorhynchus* state, a dull, sebaceous bud, has blossomed into the rounded bust that forms the *pièce de resistance* of a modern atelier.

We will confess now that, speaking for the physician, we do not feel entirely satisfied with this extreme process of evolution. It certainly would be better for babies if they could make some arrangements with high art and the manufacturers of artificial milk. They might argue, with reason, that there is no actual need for painters to represent the female form as composed mainly of two busts and a mass of tangled hair; and that it is not essential that artificial food-makers force their wares with such an aggressive pertinacity, painting the town and country with their advertisements, until a mother who nurses her child feels in a vague way perhaps that she owes a general apology to the industries of the country.

THE "PLEA FOR THE OLDER PHYSICIAN."

We have received a letter from a young physician, practising in a Western State, commenting on our editorial, "A Plea for the Older Physicians." The truth of the complaint which we published is admitted, but our correspondent seems inclined to doubt the statement that the older physicians are less pushing and noisy in their methods than are the younger of to-day. He also asserts, with rather too large an emphasis, that "young physicians as well as old are an absolute necessity." This is true; but so many young physicians as we now have are not a necessity; and it is the attempts of the aggressive and ignorant youngsters trying to crowd out the experienced and more modest elders that our first correspondent protests against.

Finally, our young correspondent writes:

"I am a young man, but, I think, honest, at least in thought. My rule is this: Never to treat my fellow-practitioner unkindly *first;* after being used badly to cut their throats whenever and wherever I can; and I find in that way, and by paying strict attention to *my own* business, I have little trouble in doing a good business for A YOUNG MAN."

We trust that we may be allowed to place a very gentle interpretation on the expression "cut their throats." But, even at its best, it represents an unchristian conduct, and one unworthy of a generous nature. The teachings of the highest ethics and the best intelligence are against the use of aggressive and spiteful modes of resentment.

We more than ever feel that our first correspondent was right in pleading for the older physicians, if the younger ones are adopting a cut-throat policy against every one whom they believe is the first to treat them unkindly.

"UNA FIDES ALTARE COMMUNE."

An ornamental scroll bearing this inscription suspended above the presidential chair of the Academy of Medicine has been a familiar sight to those who have attended the deliberations of that learned body. "One Faith at a Common Altar." It sounds effective and inspiring, whether in English or in Latin; but what is its purport with reference to the Academy? What is the interpretation? "The Common Altar" is plain enough: all are disciples of Æsculapius at the Common Altar of Medicine. But supposing that the members of the Academy were called upon to state what was intended to be conveyed by the "*Una fides,*" it is doubtful if there would be a unanimity of opinion. As this motto was adopted some time ago, it may at once be set aside that it has anything to do with the "faith cure." Possibly it means the universal faith that each physician has in his ability to cope with disease; or, again, has it reference to the "pathies," and is it, then, a battle-cry for the triumphant progress of Allopathy?

Probably the little scroll with its Latin inscription was placed by someone whose prophetic soul foresaw the danger of warring codes, and therefore gave this exordium. When viewed in this light it becomes pathetic. It is doubtful if in these days, when the spectacle of the attempted organization of the International Congress is a sight for gods and men, that the motto would have its present reading. The selection of the adjective would not have been so reckless. After consideration of *Multæ fides*, or *Nulla fides commune altare*, the whole would have been abandoned as not sounding well, and something else more general in application and less difficult of interpretation would have been selected.

VACCINATING BY CONTRACT.

The physicians of New Haven have been much disturbed over a proposition made by the city authorities to let out the public vaccinating to the lowest bidder. It appears that $3,000 being voted for this purpose, the Selectmen decided to expend the money as economically as possible, hence the adoption of strictly business methods in the matter. The New Haven Medical Association held a meeting on November 6th, in which this subject was warmly discussed, and the action of the authorities condemned. A set of resolutions was passed, in which it was announced "that it is the sense of this Association that no member should put in a bid to do the vaccinating under the proposed plan to obtain the service at the lowest cost."

The Selectmen have not, however, changed their plans.

We fully sympathize with the feelings of the New Haven medical men. Apart from any question of disrespect to the profession, it is certainly unwise and uneconomical to allow public vaccinating to be done by any but careful and competent men. Such certainly would not be likely to put in a bid for a cheap job.

Vaccinating is not a difficult or mysterious operation, but it does require intelligence and experience; moreover, by careful vaccinating many bad arms and much actual sickness can be averted. Some considerable degree of experience is also required to determine whether an inoculation has actually "taken." Altogether, we can safely assert that it is not merely professional feeling, but the dictates of common-sense, which lead physicians to condemn the putting out of vaccinating to contract. At the same time, it will be a mistake if medical men adopt any trades-union tactics, and deliberately vote to "boycott" those, if there be such, who have so much poverty of purse and of spirit that they will do cheap vaccinating by contract. An earnest protest, with a cogent presentation of arguments against cheap and irresponsible methods of getting public vaccination done, is all that the dignity of the profession requires. If there are not sound reasons against it, indignation meetings and "boycotting" will not be sufficient. There are too many poor doctors, unhappily, in our cities for such measures to avail.

If published reports do not belie it, the New Haven Medical Association went a little too far in this matter.

THE PROPOSED ENLARGEMENT OF THE AMERICAN ACADEMY OF MEDICINE.

At the last meeting of the American Academy of Medicine, held in this city recently, an amendment to its constitution was offered by the President, Dr. Gihon, which will, if adopted, quite change the character of the body in question. This amendment provides for the

admission to membership of "graduates in medicine, without literary degrees, who have distinguished themselves in medicine or the collateral sciences." By enlarging the Society in this way, the belief is expressed that a new and greater future may be opened for it, and that it may, in fact, become a genuinely national medical body, membership in which would be a coveted honor. It has for some time been observed that the American Academy of Medicine was working along too narrow lines, and was neither in full sympathy with the spirit of the times nor the most progressive instincts of the profession. It has clung too rigidly to the cultivation of an excellent but not over-fertile idea—that all doctors should be Masters of Arts. This idea is a good one, but a great national society cannot be based upon it, or upon any constitution of which that is the central piece. The American Academy, under its present constitution, must be content, therefore, to do a little good in stimulating a wider desire for preliminary education. To become anything more, its organization must be changed in some such way as has been proposed. We feel sure that its field for usefulness would be greatly enlarged by this new amendment, or one of a similar character.

News of the Week.

German Views of the International Medical Congress.—Professor Ewald, editor of the *Berliner Klinische Wochenschrift*, has an editorial in his issue of October 26th on the International Medical Congress. After giving an account of the present troubles, he laments the deposition of the old committee, and says that the German physicians will not be likely to visit a Congress that is supported by the new committee, and one that has by its peculiar policy so divided the profession. He expresses the hope, however, that it is not yet too late to amend matters, and thinks that at the next meeting of the American Medical Association, the old committee may be reinstated and that everything will yet be harmonious. We wish that such hopes were not so utterly futile. Since the extraordinary action of the Executive Committee, in declaring its independence, an action so inconsistently defended by those who claimed that the first Committee was a creature of the Association, there is little hope that that body can do anything, however strongly it may be disposed.

The International Sanitary Conference.—Public opinion, both at home and abroad, says the *British Medical Journal*, appears to agree in thinking that the International Sanitary Conference that was "adjourned" last June, is never likely to reassemble. Last week the *Popolo Romano*, referring to the fact that the 16th of next month is the date fixed for the reassembling, stated that it was not certain if the event would take place, inasmuch as several of the States which were represented when the Conference met in May last had not sent in their adhesion to the proposal for its reconvocation.

"The Florida Medical Journal" is the title of a new monthly medical journal, published at Jacksonville, Fla., and edited by Drs. T. O. Summers, C. H. Mallett, and Neal Mitchell. It is edited with spirit and shows a mastery of the rhetoric appropriate to the land of flowers. We congratulate it on not being the organ of a new medical college, as is just now too often the case with new medical journals.

The Hospitals of Rome.—A commission, specially appointed by the Royal Academy of Medicine of Rome, has pronounced a very unfavorable opinion on the hospitals of the Italian capital. It condemns the position of all, with the solitary exception of the Hospital of St. John in Lateran; but the construction and sanitary arrangements are censured without reservation.

The Russian Medical Congress.—A lengthy programme of subjects for discussion by the congress of St. Petersburg and Moscow Medical Societies, to be held from December 26th to the 31st, has been published. Among other topics the following may be mentioned: Self-help for Medical Men; Post-graduate Courses; The Best Way of Increasing the Knowledge of Ophthalmology among Russian Surgeons; Unanimity in Methods of Disinfection; Hospital Diets; Paraldehyde in Whooping-cough; Disinfection in War; Tubercular Joints; Transfusion; Antiseptic Midwifery in Hospital and Private Practice; The Need of a Special Obstetrical and Gynecological Society in St. Petersburg, and the Establishment of a Special Journal dealing with this Department.

Cholera in Spain and Italy.—Cases of cholera are still reported, but the disease continues to decline. The reports of the National Board of Health show that in Spain there were, from March 4, to September 28, 1885, 267,689 cases of cholera with 98,929 deaths, giving a mortality of 36.9 per cent.

The Small-pox Epidemic still continues with unabated activity at Montreal. During he week ending November 10th over 230 deaths were reported.

Bequests to New York Charities.—By the will of the late John P. Howard, about $250,000 is divided equally among the Association for the Relief of Respectable Aged Indigent Females in New York, the Home for Destitute Children in Burlington, Vt.; the New York Society for the Relief of the Ruptured and Crippled, St. Luke's Hospital, New York; New York Juvenile Asylum, Children's Aid Society, New York, and the New York Orphan Asylum.

Boracic Acid is largely used by milk-dealers in the summer time to preserve milk. It is, we understand, the basis of a preparation known as "vex magnus.'

Defence of a Montreal Anti-vaccinationist.—A correspondent from Montreal, M. M. Mitivier, writes us a letter defending Dr. Emery Coderre, the professor who has been fighting the dogma of vaccination. We are informed that Dr. Coderre is a gentleman of profound learning, large experience, and attractive personal character, and that he has been greatly maligned on account of his anti-vaccination views. We are glad to learn that the Montreal professor is so admirable a man. There are certain times, however, when a well-meaning anti-vaccinationist may do more harm than a whole band of murderers.

An Honor to a Medical Man.—In presenting the Albert Medal to Dr. S. C. Thompson, of Tyrone Infirmary, the Lord-Lieutenant of Ireland paid a just

tribute to the personal courage of Dr. Thompson, and took the opportunity of saying some handsome things about the professors of medicine as a body. The Earl of Carnarvon is the only English peer who has a near relative at this moment engaged in the practice of medicine, and therefore it was with peculiar fitness that it fell to his lot to make this public recognition. Such courage as Dr. Thompson has displayed, and for which he was worthily rewarded, is, we have reason to believe, common to the profession. Every day deeds of self-sacrifice, in the truest sense heroic, are done by medical men, and it is pleasant to see that they are occasionally recognized. "Every year thousands of illustrations of self-denial, self-sacrifice, and sympathy with human suffering in its most terrible forms are exhibited, and not less courage in its best and highest sense." These were the words of the Lord-Lieutenant, and they do not overstate the case. The honor done to one of its members is appreciated by the whole profession. We congratulate Dr. S. C. Thompson on his courageous discharge of duty, and on the recognition his merit has received at the hands of the Sovereign. It is somewhat remarkable that this presentation should have taken place as nearly as possible on the anniversary of the death of another medical hero—the late Dr. Rabbeth.

Office Thief.—A man is calling at physicians' offices who, in case he finds the doctor at home, represents that he suffers from some nervous affection of the scalp; is on the point of removing to this city from Detroit; may bring his family with him; is just now in some haste to go down town to keep an engagement, but will call at some other time by appointment if the doctor thinks anything can be done for him, etc.

The Constitutionality of Laws Regulating Medical Practice.—The Attorney-General of Indiana has given an opinion upon the State Medical Law, in response to the request of the Secretary of the State Board of Health, Dr. C. N. Metcalf. This law requires that in order to practise medicine a person must obtain a license, and in order to obtain a license he must have a diploma from a reputable medical college, or have practised medicine continuously for ten years in the State, or have practised three years in the State and attended one full course of lectures at a medical college. The Attorney-General is doubtful as to the constitutionality of these last two provisions, and advises a settlement of the question in the courts. Of the constitutionality of laws regulating medical practice he expresses no doubt.

The Endorsement of Medical Diplomas by Colleges.—By a resolution of its Faculty, in the future all persons intending to practise medicine in Pennsylvania, and desiring the endorsement of the University of Pennsylvania on its "diploma demanded by Section 4, of the Act of 1881, will be required to pass an examination on Chemistry, Anatomy, Physiology, Materia Medica, and Therapeutics, Pathology and Morbid Anatomy, Practice of Medicine, Surgery, and on Obstetrics; failure in any branch will cause rejection. To compensate for the labor of such examinations, a fee of $30 will be charged." The University Faculty announce that "during the last few months it has become more and more apparent that the University of Pennsylvania, if it continues to grant certificates as to the genuineness of diplomas, must issue such certificates for the diplomas of all sorts of colleges. The genuiness of the diploma is in no way dependent upon the scientific character of the body issuing it. A diploma is genuine if the body from which it emanates has a legal right to issue such diploma, and if the law is to be interpreted by the University as requiring its faculty simply to testify as to the genuineness of a diploma, it can make no difference whether such diploma is issued by a regular or irregular college. Further, the gradations between colleges in this country are so close as to make the drawing of lines a task of great difficulty, and the Medical Faculty cannot set itself up as a judge between colleges, and say that the diploma of this suffices and that does not. A very serious matter is the fact that these certificates issued by the University are looked upon by persons ignorant of the circumstances, *i.e.*, by the general community, as endorsements of the medical qualifications of their possessor, and as being in some measure tantamount to the diploma of the University. When the ease with which such genuine diplomas are obtained in America, and the little significance which so many of them have, are remembered, it becomes evident that the issue of these certificates by the University is an injustice to its own graduates." We would call the attention of the schools of our own State to this action of the Pennsylvania College. The law with us resembles that of Pennsylvania, and there is no reason why impositions may not be practised upon the Faculties of our schools.

Cincinnati College of Medicine and Surgery.—Dr. Charles E. Caldwell has been elected to the Lectureship of General Pathology. The large dispensary accepts patients only upon presentation of a card of introduction signed by a responsible person. In cases of doubt, independent inquiry is made, and when found able to pay, patients are denied the charity of the institution.

To Discuss the Medical Charity Question.—We trust that all interested in reforming the present abuses of medical charity will bear in mind the invitation of the Charity Organization Society to meet at the Academy of Medicine on Friday evening, November 20th. This promises to be a step in the right direction, and the meeting should be well attended. The times are ripe for practical suggestions, and the Charity Organization Society is able and willing to carry them out.

Out-patient Department of the New York Hospital.—It is rumored that the out-patient department of the New York Hospital is to be reorganized.

St. Francis Hospital, New York.—Examinations for the filling of the yearly vacancies on the house-staff of this hospital will be held at the hospital, December 8th, at eleven o'clock. Applications should be addressed to Dr. Joseph W. Howe, 38 West Twenty-fourth Street.

The Cocaine Habit.—Dr. A. P. Meylert, of New York, writes: "Articles on the subject of cocaine hydrochlorate are occasionally published, in which it is assumed that there is no danger of the formation of a cocaine habit. This is an error. Physicians should know that cocaine must be prescribed with considerable caution, where its administration is left at the patient's discretion. I have already had one case of cocaine habituation, complicating the morphine habit."

Obituary.

WILLIAM BENJAMIN CARPENTER, M.D., LL.D.,

LONDON, ENGLAND.

William Benjamin Carpenter, M.D., LL.D., F.R.S., F.L.S., F.G.S., the eminent English physician, physiologist, and writer on scientific subjects, died in London, November 9th, from the effects of terrible burns caused by the upsetting of a lamp while he was taking a vapor-bath for rheumatism. Dr. Carpenter, who was in the seventy-third year of his age, was born at Bristol in 1813. He studied medicine, and was graduated M.D. from the University of Edinburgh in 1839, when he began the practice of his profession in Bristol. He soon resolved, however, to devote himself wholly to scientific and literary pursuits, and in 1843 he removed to London, where his writings at once attracted attention, and he was appointed Examiner in Physiology and Comparative Anatomy in the University of London, and Professor of Medical Jurisprudence in University College. He held these positions until 1856, when he was appointed Registrar of the University of London. In 1861 the Council of the Royal Society awarded to Dr. Carpenter the royal medal for his contributions to physiological science. From 1868 to 1870 he took a principal part in the expeditions fitted out by the Government of Great Britain for the exploration of the deep sea, which yielded results of the greatest value to physical and biological science, and it was at his suggestion that the Challenger was afterward dispatched to prosecute similar researches more extensively. The honorary degree of LL.D. was conferred upon him by the University of Edinburgh, in 1871. Among his more widely known scientific works are: "The Microscope and its Revelations," "Principles of General and Comparative Physiology," "Principles of Human Physiology," "A Manual of Physiology," "Principles of Mental Physiology," and an "Introduction to the Study of the Foraminifera." He was the editor for many years of the *British and Foreign Medico-Chirurgical Review*.

Reviews and Notices.

Lectures on the Diagnosis of Diseases of the Brain. Delivered at University College Hospital by W. R. Gowers, M.D., F.R.C.P. 8vo., pp. 246. Philadelphia: P. Blakiston & Co. 1885.

It could hardly be expected that Dr. Gowers, in a small work, should deal so successfully with the subject of diseases of the brain as he did with diseases of the cord. It is indeed quite out of the question to give in a nutshell an account of cerebral anatomy, physiology, and pathology. Our author recognizes this quite fully, and has done his best to meet the difficulties, and he has succeeded in making a very useful little work.

It is put in the form of lectures, of which there are eighteen. The first three are devoted to cerebral anatomy and physiology. Of this a very good account is given. The author, however, does not describe so fully or accurately as he might the course of the afferent fibres into and through the brain.

The descriptions of the origin and relations of the cranial nerves are clearly given, but naturally present nothing more than is given by standard text-books.

The subject of symptoms is considered under the head of motor symptoms, sensory symptoms, cranial-nerve symptoms, and mental symptoms. There is very little to criticise and much to praise in the mode in which the author has dealt with this the major part of his work.

In the thirteenth lecture the subject of local diagnosis is taken up; after this, the diagnosis of the nature of the lesion, while in the last two lectures is a review of symptoms due to the various lesions to which the brain is subject.

The book is illustrated with several good diagrams.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 28, 1885.

John A. Wyeth, M.D., President, in the Chair.

Dr. L. Waldstein, from the Committee on Microscopy, presented the following report on the specimen presented by Dr. H. J. Boldt, at the last stated meeting:

"Transverse sections show that the specimen is composed of fibrous tissue in process of granular disintegration, between the fibres of which are found a series of large distended, generally rounded spaces, either entirely empty or partly filled by a finely granular mass and a delicate network of fibrin; a state of œdematous imbibition of the submucous tissue.

"As regards the muscular elements, they are comparatively rare throughout, and when they can be demonstrated they have undergone either a granular or more hyaline degeneration, the nuclei being faintly and diffusely stained by the reagent. The blood-vessels are in many cases densely filled with blood-corpuscles, and surrounded by small hemorrhagic foci; most generally, however, they are found empty and their walls degenerated, while the nuclei have entirely disappeared. The thickness of the specimen can therefore be accounted for by the œdema of the tissue and the comparative insignificance of the muscular components stands as additional proof that it is only a superficial stratum of the urinary bladder. The committee has been unable to make out any remaining epithelial covering or glandular structure."

Dr. Wesley M. Carpenter presented, on behalf of a candidate, a specimen of *primary ulcer of the duodenum*; also a specimen of *malignant disease of the liver*. The specimen was referred to the Committee on Microscopy.

Dr. L. Waldstein presented, on behalf of a candidate, a specimen of *sarcoma of the toe*.

Dr. H. Marion Sims presented

A UTERUS AND ITS APPENDAGES REMOVED BY HYSTERECTOMY.

Mrs. M——, aged thirty-eight, consulted me on October 1st of this year. She had been married eighteen years, and had one child fifteen years ago. She had always been perfectly regular in her menstrual periods, with normal flow, lasting four to five days, and never experiencing any pain with menstruation. She had been a remarkably healthy woman up to three years ago, in every respect, and had never been sick in bed for any length of time in her life. Three years ago, however, she noticed a heavy, dragged feeling across the lower part of the abdomen, with darting pains running down through the vagina and in both iliac regions. She thought nothing of it at the time, but the pains becoming more and more severe and lasting, she finally consulted a doctor, who told her she had an enlargement of the uterus that nothing could be done for. She had increased in size, and the pain becoming unbearable, she finally concluded something serious must be the trouble. She was a very large woman, weighing two hundred pounds, and I found on examination that she had a large fibroid tumor of the uterus. The uterine cavity

measured but four inches in depth, and I found the whole mass perfectly movable from side to side, and from before backward. Pressure caused pain on any side of the mass. It was determined to remove it, and she eagerly consented to an operation, fully appreciating all the dangers attached to it.

She was etherized twelve days ago, and I performed the operation, assisted by Drs. Pryor, Nash, and E. Liell.

An incision four inches long was first made, and this had to be extended to nine inches before I had room to roll the tumor outside of the pelvic cavity. After a great deal of difficulty this was successfully accomplished, a rubber ligature passed around the mass about on a level with the os internum; skewers were passed crosswise just above the ligature, and the whole mass then cut off above the skewers. Being such a large woman, with such thick abdominal fat, I closed the peritoneum muscles and fascia together with catgut ligatures, and then brought the skin and fat together with silk ligatures widely separated, placing a small rubber drainage-tube between every second of these ligatures, in order to prevent the abdominal abscesses which are so apt to occur when the adipose tissue is so thick. The stump of the tumor and uterus was securely held in the lower end of the incision by the skewers, the peritoneum being brought closely around it just below the rubber ligature. In order to prevent the projecting part of the skewers from causing sores on the abdomen and embedding themselves in the fat, I had taken warning from a former experience and had rubber plates made to place under the ends of the skewers.

The patient rallied very well from the operation, which lasted almost an hour. No nausea whatever followed, and she complained of very little pain. The next day she was bright and cheerful and had no severe pain. She had had in twenty-four hours only two one-fourth grain of morphia hypodermically. Her temperature on the second day was 100°, and her pulse only 104.

On the third day I dressed the wound and found everything progressing most favorably. Pulse was 108, and temperature 101°. About midnight of the third day she complained of a fulness of the stomach, and some tympanites. The following morning she complained still more of the tympanites, and a feeling as though something was in the stomach that she wanted to get rid of, but could not. Her temperature then was 100½°, and pulse 114. At four o'clock in the afternoon of the fourth day she complained of a sudden pain in pit of stomach, followed at once by belching of an immense amount of wind. This in turn was followed by the vomiting of at least a gallon of black water from the stomach and intestines, filled with fecal matter. One or two gasps followed this and my patient was dead. She had died of asphyxiation, from the large amount of fluid being thrown up from the stomach and intestines by the reversed action of the bowels. After death she had the appearance of a person who had been drowned.

I opened the abdominal cavity, and found everything in a beautiful process of healing. No sign of peritonitis or septicæmia was visible, and the pelvic cavity was dry and clean. I did not discover any invagination of the intestines.

The weight of the tumor after removal was nearly fourteen pounds.

PRIMARY NEPHRITIS IN A YOUNG INFANT.

Dr. J. Lewis Smith presented a specimen with the following history:

Margaretta B——, born January 28, 1885, was apparently well until July 15th, when the mother said that she had passed no urine in twenty-four hours. By one dose of sweet spirits of nitre the secretion was restored. Four days later, July 19th, the secretion of urine again ceased, but it was again restored by the same medicine. After this the child seemed well until July 31st, when diarrhœa occurred, and continued till the close of life, but without vomiting. The stools were green, and numbered from four to eight daily. On August 2d the infant had general convulsions lasting about four minutes, the only one during her illness. The eclampsia was succeeded by well-marked nervous symptoms, such as strabismus, rolling the head, twitching of single muscles and groups of muscles, the uttering of a sharp, piercing cry at short intervals, and rolling the eyes. These symptoms subsided in three days, except the rolling of the head which continued until the close of life. The fontanelles were not elevated; there was a frequent cough during the last two weeks of life, and the infant was unable to nurse. Death occurred on September 1st, at the age of seven months and three days. The temperature, taken daily during the last month of her life, was usually between 100° and 103°. It was commonly higher in the latter part of the day than in the morning. The highest evening temperature was 104° on one day, and 105° on another.

Autopsy.—Body not emaciated; alopecia over the occiput, due to rolling of head during the illness; the usual post-mortem discoloration along the back; a large amount of serum, for the age of the infant, in the cranial cavity external to the brain, estimated at from one to two ounces; brain preserved for subsequent dissection; ante-mortem clots in both ventricles of the heart; hypostatic congestion and commencing pneumonia in both lungs, posteriorly, to the depth of half an inch from the base to near the apex; anteriorly the lungs emphysematous.

In the stomach were spots showing post-mortem digestion; intestines of a pale appearance throughout; liver and spleen congested. The kidneys much enlarged; that on the right side showed cortex thickened and pale, and the pyramids large and red; hemorrhagic spots in the upper part of this kidney, and the mucous membrane of its pelvis deeply injected. The left kidney was much congested, so that blood flowed from its incised surface, and the pyramids and cortex were of a uniform red color. The capsules of both kidneys were non-adherent. The mucous membrane of the bladder was in a state of inflammation; urine retained in the bladder contained albumen in quantity nearly sufficient to solidify the specimen; hyaline, granular, and epithelial casts in great abundance; epithelial cells, red-blood corpuscles, crystals of triple phosphate and cystine.

Remarks.—It will be observed that the first symptom which attracted attention to this case was suppression of urine, which was relieved by treatment. This was followed by eclampsia and other cerebral symptoms, and diarrhœa, which continued until the close of life. It appears from the history that this patient had idiopathic nephritis, which gave rise to certain, if not all the symptoms and lesions observed in the case.

The case shows us how important it is to examine the urine in the obscure diseases of children, for we may find the kidney affected when there are no pronounced symptoms referable to this organ. The frequent occurrence of nephritis in scarlet fever has long been known. Its occurrence in a majority of the cases of diphtheria of a severe type, and in many cases of a mild type, was discovered, not many years since, by Mr. Wade, of Birmingham, and it is now known to occur occasionally in other febrile diseases, as measles and parotiditis. But I believe that the profession too much overlook nephritis in children occurring as an idiopathic or primary disease.

Microscopical examination, made by Dr. Frank Ferguson: "Kidneys of a child; surfaces lobulated, capsules loosely adherent. There are extensive superficial hemorrhages in the cortex of each organ, just beneath the capsules. There are also numerous hemorrhages in the cortex and medulla of each organ. No change noticed in the vessels' walls. In places the convoluted and straight tubules are not seen, and in these areas small, round, and spindle-formed cells are abundant. The straight tubes contain hyaline and granular casts. There is no increase in the fibrous tissue."

The Society then went into executive session.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 5, 1885.

A. Jacobi, M.D., President, in the Chair.

Dr. D. B. St. John Roosa read a sketch of the life of

JAMES L. LITTLE, M.D.,

and of the twenty-five years in which he practised surgery (see Record for November 7th).

Dr. Paul F. Mundé then read a paper on

ELECTRICITY AS A THERAPEUTICAL AGENT IN GYNECOLOGY,

which was prefaced by a brief reference to the use of this agent in obstetrics, as for controlling post-partum hemorrhage, for influencing the whole period of labor, induction of premature labor, in extra-uterine pregnancy, and for the nausea and vomiting of pregnancy.

His chief object, however, was to discuss the therapeutical application of electricity in gynecology.

The modern text-books on diseases of women casually refer in general terms to the faradic or galvanic current as a measure to be employed for certain diseases, and the manner of using the agent is briefly described in some of the works on electricity, notably in Beard and Rockwell's comprehensive text-book. Among journal articles on this subject which have attracted attention during recent years are chiefly those of Tripier and Apostoli, both of Paris, the former having lauded the value of electricity in uterine displacements; the latter, in uterine fibroids and pelvic cellulitis. Bayer has but little to say as regards gynecology, and limits his observations almost entirely to obstetrics.

Despite these various articles and the undoubted value of electricity in many of the conditions referred to, it can scarcely be said to have become popular with the mass of the profession, either in obstetrical or gynecological practice.

The range of applicability of electricity in the diseases peculiar to women was quite large enough to make it a valuable adjunct to other methods of treatment, especially as some of these affections were but little amenable to the routine remedies. Thus, the faradic current had been found useful in the various conditions of malnutrition of the sexual organs (arrest or deficiency of development of uterus and ovaries before puberty or excessive involution after parturition; amenorrhœa, irregular menstruation); deficient contraction of uterus (subinvolution, menorrhagia); displacements due to relaxation of ligaments. The galvanic current had been employed with benefit under circumstances where the melting down and absorption of adventitious products was desirable (subinvolution and hyperplasia of uterus, old plastic exudations, and adhesions from pelvic cellulitis and peritonitis, chronic oöphoritis and perioöphoritis; pelvic neuralgia, chiefly when due to pressure by exudations; fibroid tumors. And the galvano-cautery had been recommended by some authors for the cure of hyperplasia, fibroid and ovarian tumors). The use of the galvano-cautery did not properly come within the scope of this paper, since the electric current then acted merely in a secondary capacity as a heat-producing factor, the heat and not the galvanic current being the therapeutic agent.

His object was to show that it required no special talent and no prolonged study of the mysteries of electricity, and no complicated or very expensive apparatus to enable the practitioner, *who is competent to correctly diagnosticate his patient's condition and form therefrom the proper indication*, to employ the electric current *in gynecology* with safety, and in many cases with considerable benefit. In making this statement he spoke from experience; for the many excellent results which he had obtained with electricity during the past twelve years had been gained under precisely such conditions. Probably the electrologists might call the employment of electricity in this manner empiricism. Perhaps they were right; but he could only ask, was not the whole therapeutical use of the agent to some extent empirical? He should judge so, when he learned from practical electricians that it seemed to make little difference whether the current ascends or descends, or whether the faradic or galvanic current is used, so far as the therapeutical result is concerned, if only the poles be applied in the proper spots and the current be not too strong.

An experience of over ten years' almost daily use of one or the other of the two varieties of electric batteries had impressed him with several cardinal points of practical importance in the use of these instruments in gynecology.

Firstly, he had found the galvanic current far more generally used than the faradic.

Secondly, a mild, steady, absolutely painless current from a galvanic battery answered every therapeutical purpose, and was in every way preferable to a powerful or interrupted constant current, which caused painful shock or gave positive pain. As a rule, the galvanic current should produce no other sensation in the organs through which it passes than a pleasant tingling sensation in the skin to which the negative pole was applied.

Thirdly, when a constant current caused pain, or even momentarily increased the pain which it was intended to relieve, it was doing harm, and should be either reduced in strength or discontinued.

Fourthly, despite frequent inquiries of electrologists and experiments on his patients, he could never decide that it made any difference, so far as the therapeutical result was concerned, which pole—negative or positive—was placed within the body, if care was only taken not to have the current too strong, and the metal was covered by leather, when the internal electrode was connected with the negative pole.

There was one marked exception to this rule, and that was, in case it was desired to relieve pain in a certain circumscribed spot; then it was best to place the *positive* pole next to the painful point. Hence, in pelvic exudations with consequent local or reflex neuralgia, he connected the vaginal electrode with the positive pole, and attached the negative cord to the large sponge on the abdomen, sacrum, or hip, as the case might be.

Fifthly, he had always found it a safe plan to begin with a mild current (the galvanic, say four to six cells, the faradic, as much as the patient can bear without discomfort), and gradually increased to the limit, either at one sitting or day by day, and toward the end of each sitting gradually diminish the current before disconnecting the poles.

Sixthly, when internal electrization was to be employed (vaginal, vesical, or rectal), it was always well to introduce the internal electrodes before closing the circuit, and to break the circuit before removing them, since the contact of the metalicl electrodes with the sensitive skin at the orifices of the cavities mentioned, while the current was at its height, caused acute pain.

Seventhly, whether benefit would be derived from the electric treatment could not be known for some time, except when the faradic current was used to bring on the menstrual flow, the result then being either immediate or, at least, speedy, after one or several applications.

Eighthly, in order to give permanent relief, in fact, in order to derive any appreciable benefit from galvanism, it must be used often, steadily, and for a long time. Thus, less than two sittings a week was merely waste of time; every other day, or even every day, was much better than less frequently, and the sittings should vary from fifteen to thirty minutes each.

Ninthly, but while relief and freedom from pain might be often achieved by galvanism, a permanent cure, a complete absorption of the exudation, and a restoration of the organ to perfect health in hyperplasia, chronic

oöphoritis, cellulitis, and peritonitis, was seldom achieved. But this was unfortunately the case with all other methods of treatment for these obstinate affections, without even the relief afforded by galvanism.

Tenthly, he had seen no bad effects follow the rational and careful use of either form of current. A slight bloody oozing from the uterus after intrauterine electrization might occur, but was of no consequence.

CONDITIONS INDICATING ELECTRIC TREATMENT.

The pathological conditions of the female sexual organs in which electricity would be most likely to prove beneficial were the following: Deficient development of uterus and ovaries; amenorrhœa; dysmenorrhœa, obstructive and neuralgic; superinvolution; subinvolution (with or without menorrhagia); hyperplasia uteri; chronic ovaritis and salpingitis; chronic cellulitis and peritonitis, and lymphangitis; pelvic neuralgia, local and reflex; uterine displacements; erosions of cervix; uterine fibroids; ovarian tumors.

It was not his intention to make more than a passing mention of the tonic effect of the faradic, and the sedative influence of the galvanic current on the general system in the anæmia so frequently accompanying uteropelvic disease.

The author of the paper then discussed at length the use of this remedy in the above affections, and then gave the following *counter-indication*, that the rule to avoid it in all cases of acute or subacute inflammation of the pelvic organs about covered the ground, although there might be exceptions to that rule in instances of mild subacute cellulitis and ovaritis.

The conditions in which the two varieties of the electrical current act most beneficially were summarized as follows:

Faradism.—Deficient development of uterus and ovaries; amenorrhœa; subinvolution and menorrhagia; superinvolution; uterine displacements, and uterine fibroids (interstitial).

Galvanism.—Hyperplasia uteri; chronic ovaritis and pachy-salpingitis; chronic cellulitis and peritonitis, and lymphadenitis; pelvic neuralgia, local and reflex; dysmenorrhœa, neuralgic and obstructive; erosions of cervix; subinvolution, and uterine fibroids (subperitoneal).

The conclusions to be drawn from the experience detailed in the paper were the following:

1. Electricity locally applied was a valuable agent in gynecological practice, and should be more widely used than it was.

2. It did not require special knowledge or experience as an electrologist to be able to use the agent safely and beneficially in gynecological practice.

3. The remedy, if properly used and on correct indications, could not do harm.

4. It should be used only in chronic conditions, and if it was the galvanic current, should give no pain.

5. The conditions in which the faradic current was indicated were chiefly those characterized by deficient development or want of tone of the sexual organs, such as imperfect development of uterus and ovaries, superinvolution, subinvolution, amenorrhœa, uterine displacements, interstitial fibroids. The object of the faradic current was to stimulate the organs to increased growth or activity, and to produce muscular contraction.

6. The conditions in which the galvanic current was indicated were those in which it was desired to promote absorption of adventitious products, chiefly the result of previous inflammation; to allay pain, to excite reparative action, and occasionally to act as a caustic. The rapidly interrupted galvanic current, however, also excited muscular contraction.

7. Perseverance in the treatment was essential to success.

8. Acute and subacute inflammatory conditions, as a rule, counter-indicated local treatment by electricity.

9. The pathological conditions in which electricity proved useful were such as those in which other treatment often failed or could not be borne by the patient.

10. In organic diseases a permanent cure, or a restoration of the diseased organs to perfect health, could usually not be accomplished by electricity, but great relief from pain, and certainly temporary improvement in otherwise intractable cases could be achieved by it, without danger and with comparatively little discomfort to the patient.

Dr. John N. Freeman, of Brooklyn, on invitation, opened the discussion, and said that in nearly every particular Dr. Mundé's paper coincided with his experience. He began the use of electricity with the faradic current twenty years ago, and at that time almost entirely empirically, yet with valuable results in many gynecological cases, and often with disappointment.

Sixteen years ago his old dyspepsia began to be attended by attacks of severe gastralgia, and for the relief of the distressing pain he began, at the suggestion of the late Dr. Geo. M. Beard, the use of electricity, first with the faradic, without much benefit, and then with the galvanic current, and was completely cured. Since that time he had used the galvanic current almost entirely, until he began the use of *static* electricity, with which he had obtained very satisfactory results in gynecological practice. He now employed static electricity in about the proportion of 40 to 1 of all other varieties, and one special advantage was that it could be applied through the clothing.

A special benefit attending the use of electricity was the relief from pain which it afforded, thus obviating the use of opium. For example, gynecological manipulations involving the endometrium were frequently followed by intense pain, but this could be quickly relieved by the application of static electricity.

With regard to electricity in the treatment of fibroids, he had seen the patient referred to by Dr. Mundé very recently, and ascertained that the tumor had not given her any trouble whatever since treatment by electrolysis.

Dr. Freeman related the history of a case referred to him by Dr. A. S. Clark, in which the fibroid was as large as an ordinary-sized cocoanut, to which the bladder was adherent, accompanied by cystitis, and the tumor pressed backward so firmly that constipation was a prominent symptom. He introduced the positive pole into the interior of the uterus, and attached the negative pole to a needle thrust through the anterior abdominal wall into the tumor, using thirty-two cells (galvanic) for a little more than half an hour: no severe reaction followed. At the second sitting, two months later, the fibroid was very much softened and diminished in size nearly one-half. Two months subsequently the tumor was treated again, and two months after the last application the patient was able to be about the house, and now is in excellent health, although there remains some thickening of the anterior wall of the uterus, and she still has some pain. The uterus is about normal in size.

Dr. Freeman also related the history of another case in which there were two tumors, and both were removed by electrolysis. In neither of the three cases did the temperature rise above 99° F. after treatment.

Dr. A. D. Rockwell could confirm in great measure the statements made by Dr. Mundé, and believed, as he had often said, that while electricity was a remedy which had a wide range of usefulness, it should be used with care and caution. In the treatment of the sequelæ of pelvic cellulitis, he was unable to understand how any gynecologist could get along without it, especially for promoting the absorption of old adhesions and thickenings. With regard to subinvolution of the uterus, he would expect theoretically, and had found it so clinically, that galvanism was more beneficial than faradism.

The subject was an exceedingly interesting one to him,

and he had had more or less experience in the use of electricity in all the classes of cases of which the author of the paper had spoken, but time did not permit him to refer to them in detail.

Dr. H. J. Garrigues said that all were indebted to Dr. Mundé for bringing forward a subject which should receive more attention than it had yet received. He had used electricity more or less in gynecological practice during the last thirteen years, and the chief reason why he had not employed it more than he had done was because the proper application consumed so much time; besides, he had been able to obtain equally good results by the use of other remedies, which could be easily applied with the consumption of less time.

The condition for the relief of which he had resorted to its use most frequently was *amenorrhœa*, although it had not always served him well in those cases; not only where the uterus was defective, but where the condition seemed to be merely functional. The simple introduction of a sound, with the internal administration of iron, had served him about as well as any plan of treatment he had ever adopted.

With regard to the use of electricity in the treatment of uterine fibroids, he had recently read a report by a French author, who had used it with special benefit in one hundred and eighteen cases. As to the hemorrhage, however, which so commonly accompanies fibroid of the uterus, Dr. Garrigues would recommend the use of *cotton-root*.

In the use of the galvanic current he had, with one pole within the vagina, seen unpleasant results by way of producing an eschar, although he had used a smaller number of cells than advised by Dr. Mundé, and also had covered the electrode with several layers of muslin.

Dr. W. R. Birdsall regarded the literature of the subject as rather mystifying and unsatisfactory. On general principles he had but little to add to the conclusions given by Dr. Mundé, which, on the whole, represented sound views.

One difficulty in studying the question is in ascertaining what observers have used, and how they used it. Better results would be obtained when more exact methods were employed, and until the strength of the current was reckoned by milliamperés, and the galvanometer was employed, science would not get the benefit of good observations and results.

The conclusion reached by the author of the paper, that electricity should not be used in acute and subacute cases, Dr. Birdsall regarded as exceedingly important.

Dr. Malcolm McLean spoke of the efficacy of electricity in the treatment of those cases which, by many, would be regarded as suitable for Tait's operation—an operation performed too frequently, and the benefits of which are not so lasting as has been supposed.

Dr. H. J. Boldt mentioned three cases of metrorrhagia and menorrhagia in which cure was affected by the alternate use of faradism and galvanism.

The discussion was closed by Dr. Mundé, who said that the points referred to by those who had participated in the discussion had been discussed in the parts of his paper which, on account of lack of time, he had omitted to read. He had, however, not used static electricity. The main object of the paper was to direct attention to the benefit which might be derived from the use of this remedy, and thus to make it more popular in special and general practice.

ANNIVERSARY MEETING.

The President announced that Dr. Janeway, on account of ill-health, had resigned his appointment as orator for the anniversary meeting, to be held November 19th.

It afforded him great pleasure, however, to give notice that the anniversary discourse would be delivered by Dr. Henry D. Noyes.

The Academy then adjourned.

FIFTY-EIGHTH CONGRESS OF GERMAN NATURALISTS AND PHYSICIANS.

Held in Strassburg, Germany, September 18 to 23, 1885.

(Special Report for The Medical Record.)

Nearly one thousand of the scientists and physicians of Germany and Austria were present at the opening of the first

GENERAL SESSION,

held in the large hall of the University at Strassburg.

THE ADDRESS OF WELCOME

was delivered by Professor Kussmaul, who dwelt upon the scientific history of Strassburg, and recounted the great names which had been associated with this city from the time, one thousand years ago, when Ottfried sounded God's praises in the German tongue, down to the present. The speaker then summarized the history of the growth of the University from the year 1621, when the Emperor Ferdinand III. raised the then existing academy to the rank of a university.

Other addresses were made by von Hofmann, Sempel, and Virchow. Berlin was selected as the next place of meeting for the Association, and then the session was adjourned, the members repairing to the different halls in which the Sections were to meet.

SECTION FOR INTERNAL MEDICINE.

Herr H. Eichhorst, of Zurich, presented the first paper, on

HEAT RADIATION FROM THE HUMAN BODY

in conditions of health and disease. By means of a delicately constructed apparatus the speaker and Herr Masse had made a number of observations upon the radiation of heat from various portions of the body. They found that this was greater from the trunk than from the face, and from the flexor than from the extensor surfaces. There was no perceptible difference between the two sides of the body. One interesting fact was observed, viz., that there was no obvious parallelism between the surface temperature and radiation. Thus, in a case of epididymitis, although the skin covering the inflamed part was hotter than that on the healthy side, it nevertheless gave out less heat. In fevers, also, the radiation of heat is not invariably increased in proportion to the degree of elevation of the body temperature. Quinine, kairine, cold baths, and other internal and external antipyretics had the effect of greatly increasing the radiation from the body in fevers, and to this, probably in great degree, was due their power of lowering temperature. The speaker exhibited the instrument which had been used in his investigations.

Herr Vierordt, of Tübingen, had devised an instrument for

MEASURING AUSCULTATORY SOUNDS,

as regards their force and degree of intensity. His investigations had shown that the first mitral tone is loudest of all the heart-sounds, being more than three times stronger than the first aortic sound. He gave the comparative degrees of force of the other sounds also, as he had measured them with this instrument.

Herr Stein, of Frankfort, exhibited a number of batteries for use in

ELECTROTHERAPEUTICS,

which he considered preferable in many respects to those in common use. He also showed several Edison lamps for illuminating different cavities of the body.

Herr von Jacksch, of Vienna, read a paper on the presence of

VOLATILE FATTY ACIDS IN THE URINE.

Normal urine, the author said, contains occasional traces of these substances. In fever there is a consider-

able increase of the fatty acids. Lipaciduria is also seen in liver affections accompanied by destruction of the glandular parenchyma, and in leucæmia. This condition, as well as acetonuria, the speaker believed to be due to increased disintegration of albuminous substances. If the fatty acids—butyric, acetic, and formic—be separated from the urine of healthy individuals or of those suffering from fever or hepatic disease, it will still be possible, by the addition of oxydizing agents, to obtain in all three cases volatile acids.

Herr Schuster, of Aachen, related a case of supposed

MULTIPLE SCLEROSIS OF THE BRAIN AND SPINAL CORD OF SYPHILITIC ORIGIN.

The patient had difficulty in locomotion, oscillation of the eyeball, resembling nystagmus, upon attempted fixation, uncertainty in muscular movements, a feeling of constriction about the body, exaggerated tendon reflexes, and tenderness over the spine. The man presented at the same time unmistakable evidences of syphilis. The nervous as well as the syphilitic symptoms disappeared almost entirely under the use of mercurial inunctions.

Herr Rumpf, of Bonn, read a paper on

SYPHILITIC MONOPLEGIA AND HEMIPLEGIA,

in which he sketched the varying symptoms and sought to explain the uncertainty of prognosis which existed, even when the treatment was apparently most suitable. He then related four cases in which a diagnosis of syphilitic cortical disease was made from the co-existence of monoplegia with spasmodic symptoms, and from the antecedent history. In two there was motor paralysis without any changes in sensation, and in the other two there was no paresis, but a very marked diminution of tactile sensibility, and especially of muscular sense. The first two the author regarded as disease of the motor centres, and the last two as "cortical disease of the sensory area." From a study of these cases he concluded that the centres of motion and of muscular sense were not identical.

SECTION FOR DISEASES OF CHILDREN.

Herr Pfeiffer, of Wiesbaden, read a paper on

RACHITIS,

in which he referred especially to a number of analyses he had made of the milk of women who were nursing rachitic children. In all these cases the older children, as well as the mother herself, presented signs of former rickets. The infants seemed to be well nourished, and the supply of milk was ample. As a rule, the milk differed but little from the normal. In some cases there was a diminution in the proportion of salts. In two there was an increase in the relative amount of calcium salts, and in two others the analysis showed a deficiency in phosphoric acid.

Herr Kassowitz, of Vienna, thought that great caution was necessary in drawing conclusions from these analyses as to the etiology of rickets. In the first place, it should be remembered that the disease was not uncommonly seen in the new-born before they had begun to nurse, and in other cases its commencement was observed in children three or four years of age, who had been weaned long before. He did not regard the phosphorus treatment of rachitis with favor.

Herr Unruh, of Dresden, believed rickets to be a congenital disease, and independent, as far as its etiology was concerned, of the quality and quantity of nourishment received.

Herr Lorey, of Frankfort, asked why the specific gravity of the milk had not been taken. He believed that if the mother's milk was sufficient in quantity and had a specific gravity of 1.030, together with a normal proportion of cream, the child would not become rachitic.

Herr Pott, of Halle, read a short paper on

GASTRO-ENTERITIS OF CHILDREN,

and said that he had obtained excellent results with tincture of coca. He also claimed to have been very successful in the

TREATMENT OF PERTUSSIS WITH COCAINE,

using a five per cent. solution in local applications.

Herr von Dusch, of Heidelberg, thought that cocaine could hardly be curative of whooping-cough, by reason of its transitory effects, but he acknowledged that it was of exceeding value as a palliative measure.

Professor Kohts had used

COCAINE IN DIPHTHERIA,

but was not particularly pleased with the results obtained. In tubercular ulceration of the glottis he had, however, seen excellent effects produced by cocaine in five or ten per cent. solution.

Herr Ranke, of Munich, read a paper on

TRACHEOTOMY IN DIPHTHERIA.

He had operated, in the course of the last seven and a half years, upon 45 cases, 19 of which resulted fatally, and 26 recovered, giving a percentage of recoveries of 57.7. This was regarded as very good for Munich, where previously the mortality following tracheotomy had been very high. The speaker advocated thorough ventilation in these cases, and had two rooms, in one of which were the patients while the other was being thoroughly aired, and the children were changed from one to the other room several times a day. He permitted no furniture in the room except iron bedsteads, a few chairs, and a table or two. The operation was not performed in this place, but in the clinic or at the patient's residence, and then the child was carried to the infirmary in a carriage. Herr Ranke had never seen any evil consequences follow this transportation. He operated early in the disease, as soon as the vocal and respiratory symptoms of laryngeal invasion became manifest. He admitted that some of his cases might have recovered if let alone, but he doubted not that at least ninety per cent. would have died if not operated on. After opening the trachea, he was accustomed to wait a while before inserting the tube, so as, if possible, to get rid of some of the false membrane. During the first few days he used steam without any other medication. The canula was changed only on the third day, as a rule, but if the false membrane formed on the tracheal wound the canula was changed once or twice a day, the wound being then covered with a cloth dipped in a three per cent. carbolic solution, and the canula plunged into boiling water and thoroughly cleansed.

SECTION FOR PATHOLOGICAL ANATOMY.

Professor Orth, of Gottingen, read the first paper, detailing the investigations he had made in regard to the

ETIOLOGY OF ACUTE ENDOCARDITIS.

He said that he was able to affirm that valvular disease of the heart was not always of parasitic origin, for in none of his microscopical examinations of the so-called acute verrucous endocarditis had he discovered any micro-organisms, and culture experiments had likewise given negative results. As to the question of the special form of micro-organism which was concerned in the etiology of parasitic valvular disease, he was unable to answer with certainty. In one case of malignant ulcerative endocarditis, he had found vast numbers of staphylococcus pyogenes aurens. In experiments upon animals he had induced fatal endocarditis by introducing this micro-organism into the circulation, while injections of other varieties of microbes were negative in their results. In these experiments the cocci were found always on the surface, so that it seemed that they were deposited from

the general blood-current and not primarily in the vasa vasorum. They were deposited only in those places where there was an injury to the endocardium, but this injury might be very insignificant and consist only in a slight unevenness of the surface.

Herr von Recklingshausen stated that he had seen cases of secondary endocarditis in pyæmia and pulmonary phthisis, in which the warty excrescences had formed upon previously normal endocardium.

Herr Ribbert, of Bonn, then read a paper entitled

THE LOCALIZATION OF INFECTIOUS DISEASES,

in which he attempted to show that certain organs are attacked by the specific microbes because the latter are held mechanically in these localities, and not because, as is more commonly supposed, they find only there the conditions essential to their growth and development. He instanced in favor of this theory some experiments which he had made with the spores of mykosis, which seldom give rise to inflammatory foci in muscular tissue. Thinking that a possible explanation of this dissemination was that the spores were too minute to be arrested in the capillaries of the muscles, he cultivated them for a time, until they had advanced so far in their development as to be too large to pass readily through the smallest vessels, and then injected them into the circulation. He found that then the spores were arrested in the muscular tissue, and as a consequence there were many spots of inflammation in this location. In a second series of experiments the author injected pure cultures of staphylococcus flavus into the circulation, and found that they gave rise usually to a myocarditis, but sometimes also to endocarditis. In the latter case he found, contrary to the experience of the author of the preceding paper, that the micro-organisms were arrested on the valvular endocardium even in cases in which there was no roughening or previous lesion of this membrane.

Herr Virchow said that it was impossible that the microbes could in all cases be carried to the valves solely by the vasa vasorum, for there were portions of the latter, as the chordae tendineæ, which were absolutely non-vascular. But these portions were also frequently the seat of endocardial inflammation, and it was impossible for micro-organisms to be carried to such localities except by the general intracardial blood-stream. He himself, however, had never seen endocarditis following intravenous injections of micro-parasites, although he had made numerous experiments of this nature.

Treatment of Acute Rheumatism by Cold Sponging.—Dr. R. H. Fox, in the *British Medical Journal*, says: "Beshara Bey, M.D., Friends' Hospital, Brumana, Mount Lebanon, in a recent letter to me, described a severe case of rheumatism, in which salicylate of soda, potash, quinine, colchicum, and liniments, all failed to relieve the fever and the pain. Almost in despair, he sponged the patient with cold water, quickly drying the skin afterward. The relief was immediate, and the man was able to walk a short distance to his home in six days from that time. Dr. Beshara wrote that he had used the same treatment in two other cases with success."

Another Case of Gonorrhœa in a Boy.—Dr. W. W. Greer, of Rockdale, Tex., writes: "In The Medical Record of August 15th is reported a case of gonorrhœa in a boy seven years old. I can beat that record by one year. In October, 1884, while practising medicine in Atlanta, Ga., I treated a negro boy six years old for gonorrhœa. He had been sleeping with a girl seventeen years old, whom I had previously treated for the same disease. The boy was carried before the class at the medical school, and the diagnosis was sustained by Dr. James A. Gray, who had charge of the venereal clinic."

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE COLLEGE OF PHYSICIANS—THE BALY MEDAL—THE HARVEIAN ORATION—DR. QUAIN AND "THE TIMES"—THE COLLEGE MEETING AND THE DOCTORATE—THE FELLOWSHIP OF THE COLLEGE—THE MEDICAL SOCIETY OF LONDON—A NEW THEORY OF FEVER-HEAT—A LIFE DEVOTED TO SCIENCE—THE BEST EDUCATION FOR A PATHOLOGIST.

London, October 24, 1885.

We have had rather a lively week in London, and the College of Physicians is to the front. In their hall, on Monday, the annual oration was delivered; after which the President presented the Baly Medal to Mr. William Kitchen Parker for his researches in minute comparative anatomy, particularly the anatomy of the skull. The Baly Medal, in memory of Dr. Baly, is awarded once in two years as an acknowledgment of original work or research. In presenting the medal to Mr. W. K. Parker, the President (Sir W. Jenner) complimented him on the work he had achieved while engaged in general practice, and said he could appreciate this as he had begun his own career as a general practitioner.

The oration preceding this presentation is the annual ceremony in memory of Harvey. Dr. Richard Quain was the appointed orator, and took for his subject "The Progress of Modern Medicine." He tried to answer the question, why the profession is so little appreciated, and to vindicate it from the flippant assertion that it has made no advance since the time of Hippocrates; an assertion which was rather a query in the mouth of a deceased politician. Dr. Quain had no difficulty in substantiating the claim he made for progress, since he could point to the microscope, the ophthalmoscope, the laryngoscope, the sphygmograph, etc., as proofs of more accurate work, and could cite chloroform, chloral, bromides, salicin, and other agents as indices to therapeutical triumphs. Besides, was he not speaking to those who used these resources of modern practice? But he had also a larger audience. He obviously spoke to the outsiders, too, and the next morning some of the purists among his dear confrères were scandalized to find a report of his oration in *The Times*, together with a leading article founded upon it. Was it not shocking? Here was evidently a man who would speak to *The Times*, a "lay paper"—and get a report in the "lay press" of his lecture—"quite an advertising dodge." These and still less complimentary remarks were made by gentlemen too pure to hold any communication with the public press. There was no jealousy—oh! no. It was only the honor of the College and the profession that so upset those who have not the opportunity of dining with the editor of *The Times*. If they had that chance—who knows?

Then, again, the College itself has sought publicity—has thrown off some of its old traditions; and, though it still officially condemns every kind of publicity, announces its lectures in the public press, and is generally understood to consider respectable the publishers' columns of the daily papers. What nice distinctions—nay, what ridiculous squeamishness. Or rather it must be that they who have risen in life may do anything, but struggling men must be denied the help by which those who deny them have got up the ladder they are so delighted to kick down.

But there is more about this ancient College. During the week an adjourned meeting has been held to discuss whether, jointly with the College of Surgeons, it might not undertake to confer the doctorate, and a pretty discussion ensued. I have before informed you that London students are practically debarred from obtaining the coveted degree of M.D., which is easily gained by Scotch

and Irish students. This is a monstrous injustice to England, and the wonder is that it has been patiently endured so long. The two colleges having lately agreed to work together, and to give their double diploma; it is suggested that those who thus become qualified ought to be dubbed M.D., or at least M.B. Others think it would suffice for them to be called Dr., without having the liberty of writing M.B. or M.D. after their names. The truth is that the Colleges have no power to grant degrees; and, if they seek a new charter, with extended powers, they may be compelled, as the price, to grant some urgently needed reforms. So some assume the right, and, reposing on the notion that every physician is a doctor, licentiates of Colleges of Physicians use the prefix Dr. It is now proposed that the two colleges recognize this "courtesy Dr." so far as holders of the conjoint diplomas go. This would go far to settle some disputes, but every otherwise legally qualified practitioner would have just as much legal right to such courtesy, and we should all become veritable doctors and real professional brothers. But this enrages the possessors of the University M.D.'s, and that, too, though their university may be inferior. Anything to make a clean sweep of a contemptible bone of contention would be a blessing to the profession, and there is some chance of a compromise being effected, as it promises to replenish the coffers of the College of Physicians; and, after all, it is money which weighs most there. The stupid fiction is still kept up that the Fellowship of that College is obtained by merit, whereas it is the fact that this diploma is given by election of the Council—that is, to those who are personal friends of councillors, or who feast them at dinners, or, being too poor for that, toady them until nominated. As I explained to your readers three or four years ago, there are hospital physicians and lecturers who are still kept out in the cold, while their juniors find the way to become Fellows. Sir W. Jenner was so liberal as to propose to admit a few general practitioners. Had he proposed a simple act of justice to teachers before an act of generosity toward others, his motives would have been less open to misconstruction.

The Medical Society of London opened this week, with an address by the President for the year, Dr. Ord, who propounded a new theory as to the increase of heat in fever. He found increased combustion an unsatisfactory hypothesis, and thinks there must be, with arrested metabolism, no use for the heat which that process ought to render latent, and which therefore remains kinetic. He illustrated his meaning by the facts observed when a metallic vessel containing water is heated. We shall hear much more of this, and it will be a relief to have a different figure instead of the few that have been so worn as to be fairly worn out.

Dr. Ord's dissatisfaction with the prevailing theories started from a statement of Dr. Burdon-Sanderson's, in his paper on "Fever."

This last-named Professor delivered an address at University College last week on "A Life Devoted to Science." The life he took as an example was Cohnheim's, and he gave a précis of Professor Kühne's recent biography of that eminent pathologist. As to such a life in England the openings are few, and Dr. Sanderson said if he were asked how to give up a life to pathology, he would advise the aspirant to qualify for the medical profession, take resident appointments as if he intended to practise, and after that make up his mind whether to do so or to cultivate pure science only.

MEDICAL EDUCATION AND PRACTICE IN HOLLAND.

To the Editor of The Medical Record.

Sir: No country presents more of interest to the average foreigner than Holland, for in its cultivated fields, its many canals, its curious houses with their quaint roofs and chimney-pots, he sees a true picture of the ideal he has conceived from reading and the representation of others. The energetic little people, in their grotesque peasant costumes, seem to be *in* our world, but not *of* it, for the Hollander has a world of his own that has never thrown open its gates to foreign manners and customs; although almost entirely hemmed in by the diverse civilization of England, France, and Germany, it holds its individuality with a methodical, instinctive, self-contented grasp that characterizes the Dutch people. Wherein the individuality of this people lies has been the theme of many books, but the study and practice of medicine in Holland presents peculiarities that have more or less escaped general notice, the narration of which may be of interest.

There are universities at Leyden, Utrecht, Groningen, and Amsterdam. These are all under the control of the Government. The first three are supported by the State. The professors receive their appointments from the State, on the recommendation of the faculty, and generally on their merits. At Amsterdam the university is supported by the city, professors are nominated by the city government, subject to confirmation by the king. At the age of seventy all professors are retired on two-thirds pay. In the session of 1884–85 there were enrolled at all the universities 2,220 students, about one-half of whom, 1,054, were students of medicine.

Generally speaking, we may say that the medical course proper occupies five years. The student, as a rule, is obliged to spend two years at the university studying collateral sciences preparatory to the study of medicine, making seven years at the university. The element of time, however, is not taken into consideration; after passing one examination the student is allowed to present himself for the next, nor is he asked where he acquired his knowledge. They are absolutely free to attend lectures or to remain at home, to study or to play. As a matter of fact, a few get over the course in less time than I have indicated, some remain longer at the university, while a few never get through at all. The course of study differs slightly for those who want the degree of M.D. from that pursued by those who are satisfied with the title of "arts." For the former the preparatory studies are more extensive and the examinations are somewhat harder. These are held by the faculty representing the university, while the "arts" students are examined by a committee appointed from the faculty, who act on behalf of the State.

The following is an outline of the curriculum of study:

Preparatory.—The candidate for the degree of M.D. takes a course of six years at the gymnasium before entering the university, while the "arts" student need spend only four years at the gymnasium, or in lieu of that, five years at the "hoogere burgerschool," corresponding somewhat to our high school; but the student from this high school cannot secure the degree of M.D. unless he at this time pass the final examination of the gymnasium in Greek and Latin, which he is permitted to do without having attended that institution.

The seven years at the university can be divided as follows:

First examination: Mineralogy, physics, chemistry, botany, zoölogy, and comparative anatomy, two years. Students from the high school often pass this examination after one year, because they have had more of these studies than those from the gymnasium.

Second examination: Anatomy, physiology, normal histology, general pathology, and pharmacology, two years. After this examination the future M.D. is called a medical candidate.

Third examination: General and special pathology and histology, pharmaco-dynamics, therapeutics, clinical medicine, surgery, obstetrics, and hygiene, two years. After this examination the medical candidate is entitled to be called medical doctorandus.

Fourth examination, called the "practical arts" examination: Practice of medicine, surgery, gynecology,

obstetrics, pharmaceutics, and ophthalmology, one year. This examination is held by a committee appointed by the Government, and entitles those who pass it to practise medicine in all its branches with the title of "arts." It must be passed by all, as the degree of M.D. confers no right to practise.

Before presenting himself for this examination the student must have had charge of twelve confinements, two of which must have been artificial deliveries. In addition to the above, the M.D. must write a thesis and defend twelve propositions before the faculty, but this may be done before passing the "practical arts" examination. Other medical degrees conferred by the university are Doctor of Surgery and Doctor of Obstetrics. They are given to Doctors of Medicine on passing an examination, writing a thesis, and defending twelve propositions on each subject. These degrees are seldom taken at present, the title of "arts" giving the right to practise in these branches. After passing his final examination the "arts" frequently resorts to Germany, where he can obtain the coveted M.D. degree in about six months. The M.D.'s are for the greater part from the best families; the "arts" are recruited from all sources. Lectures are given mostly in the morning; the afternoon is given to laboratory work, dissecting, etc.; the evening to study or social enjoyment; but the habits of the students vary considerably.

The tuition is $80 a year, for four years, after which attendance at the university is free. There are no private colleges. Private courses, for which extra charges are made, are given only by assistants and private docents.

Holland does not offer the facilities for post-graduate study that some other countries do. For this purpose the Dutch resort to some of the large cities of Europe—Paris, Vienna, and Berlin being favorite places. Foreign students are scarce. An occasional student of ophthalmology is attracted to Utrecht by the names of Professors Donders and Snellen. The former has the chair of physiology, the latter that of ophthalmology. Foreigners are allowed to practise on passing certain examinations. Homœopathy does not exist, but patent medicines and other quackery abound. There is only one lady physician in all Holland, but there are three or four students at some of the universities. Fees in small cities average about forty cents a visit; obstetrics, five dollars. In Amsterdam from forty cents to a dollar is an average for visits; obstetrics, from five or ten dollars up. In wealthy villages most people will pay from thirty to fifty cents a visit; the very poor are treated at the expense of the corporation. Many of the latter are members of benefit societies, that furnish medicines and medical attendance at from one to two dollars a year. There are many of these benefit societies in all parts of Holland. They differ greatly in detail; most are for the poor only; but there are a few which any one can join. In some the physicians are paid a regular salary; in others they get so much a head, eighty or ninety cents per year; while in others the profits are divided between the doctors and the druggists. There are no dispensaries, excepting those connected with the universities. Doctors are not allowed to dispense medicines, unless it be in small places where there are no drug stores.

The local medical societies send one delegate each to the Medical Society of the Netherlands, which meets once a year. The delegates vote according to the membership of the societies they represent. Several medical journals are published. The *Weekly Medical Journal*, the organ of the above society, is the most important. The surgeons of the colonial army have until quite recently been supplied from foreign sources, but of late the State has given aid to medical students on condition that they would enter the service. After passing the first examination at the university the student may make a contract with the Government, by which they agree to serve eight years after graduating. While attending lectures they are entitled to $320 a year, and a like amount after passing each examination. The home army and the navy have always been supplied with native doctors.

The profession is not so crowded as in America, and, on the whole, seems more prosperous, but they envy us our higher fees. FRANK T. SMITH, M.D.

THE VULGARIZATION OF MEDICAL SCIENCE AND THE DISREGARD OF MEDICAL ETHICS IN NEW YORK.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: It may not appear consonant with the competitive life and advertising enterprise which our facilities in turning out doctors (like "Spanish in six easy lessons") to touch upon the sanctity—for it should be a religion—which should characterize the vocation which is made the recipient of the most delicate, nay the most painful, confidence. Its representatives in distress are looked up to as soul-stricken penitents look up to their Maker. It is possible that there are some physicians who read this who have realized, in the dire suffering of those most dear to them, that I am not grandiloquent nor poetical. Even in remote heathen times the practice of medicine was often conducted with sacred rites. But in this country (*only*, so far as I know) the details and intricacies of disease, complex and perplexing enough to the diligent student of medicine, are held up to the gaping public who gaze upon them with the oblique and dim eyesight of ignorance.

The rasping of the saw upon the bones, the flow of blood, the quivering of the flesh, are described in daily papers with sickening detail. The true physician, the high priest of nature and of the home, if he be true to his calling, does not enjoy such details. He recognizes them, but only as a part of his duty, and not as a sort of magic lantern for vulgar exhibitions. A portion of this letter owes its inspiration to a prominent article in this morning's *Tribune*, headed in big caps: "Removing a Huge Tumor—The Different Steps that were Taken." The article occupies three-fourths of a column. It is an account of an operation at one of our best (the Mount Sinai) hospitals. Here are a few lines from it: "A leaden paleness spread over her face, the muscles of the abdomen contracted convulsively," "her breath came in short sonorous gasps." "A sharp knife" (of course the public, except for this *description* of the knife, might think that dull knives were usually employed in surgery) "was inserted into the flesh at about two inches below the umbilicus," etc. Now in whose interest, *et cui bono*, all this is published it is hard to tell, as, perhaps singularly, the surgeons' and patients' names are not given. I would not descant upon this subject, but there come under my observation constantly other instances of violated medical ethics, etiquette, and humanity. I believe we have in New York the best gynæcologists anywhere, and I, as a general practitioner, avail myself often of their skill, but I know several of the best of them who cannot refrain from telling me the names and ailments of many of their female patients—these same physicians even tell lady patients the names and diseases of other patients.

Now some women suffer so long with the unfortunate complaints to which their sex is subject, that they become indifferent to the nature of their ailments being known, but many of my patients have told me that the gynæcologists whom I recommended told them about this and that lady's complaint, and that naturally enough they thought they were in the same box. These diseases are afflictions, and many women shrink with horror at their being generally known; still, through my patients and through doctors, the amount of knowledge that I profess about ladies I do not treat would be regretted I am sure by many of them.

A physician has no right, even in a thoughtless way, to disclose the names and diseases of his lady patients. It

would not be a bad thing, either, if ladies could go to gynæcologists without meeting with gentlemen in the reception room, the bare fact of ladies being there indicating the nature of their complaint. *Ohe! jam satis!* The signing certificates of wines which are not what is claimed for them, of hypophosphites which are not hypophosphites, of mineral waters which have never been properly analyzed, etc., I will touch upon another time, making due allowance for the fact that the sweetness of dying for one's country is as nothing compared with the sweetness (to many physicians) of seeing their names in the papers.

I have the good fortune, Mr. Editor, to have been known to you for many years, and I know you will credit what I have said. Respectfully yours,

A STRAIGHT-LACED DOCTOR.

NEW YORK, November 2, 1885.

THE MEDICAL CHARITY QUESTION.

TO THE EDITOR OF THE MEDICAL RECORD.

CHARITY ORGANIZATION SOCIETY OF THE CITY OF NEW YORK, November 6, 1885.

SIR: Will you kindly give notice in your next issue that in compliance with many requests from officers in charge of medical institutions the Charity Organization Society invites the medical staffs, and the boards of managers of the several hospitals and dispensaries of the city, to meet at the hall of the New York Academy of Medicine, on Friday, November 20th, at 8 P.M., to confer together concerning the existing abuses and misapplication of medical charity, and to consider how these abuses may be remedied, through the registration system and other facilities of the Charity Organization Society.

Yours very truly,

CHARLES D. KELLOGG,
Organizing Secretary.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 1, 1885, *to November* 7, 1885.

MCCLELLAN, ELY, Major and Surgeon. Leave of absence granted in orders, Cavalry Depot, Jefferson Barracks, Mo., October 30th, is extended seven days. S. O. 254, A. G. O., November 4, 1885.

EBERT, R. G., Captain and Assistant Surgeon. Ordered from Camp Grant, Riverside Park, New York City, to Fort Hamilton, New York Harbor, for duty. S. O. 237, Department of the East, November 5, 1885.

BUSHNELL, G. E., First Lieutenant and Assistant Surgeon. Assigned to duty at Camp Grant, Riverside Park, New York City. S. O. 237, Department of the East, November 5, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 7, 1885.

KINDLEBERGER, DAVID, Medical Director. Granted leave of absence to June 30, 1886, with permission to leave the United States.

WIEBER, F. W. F., Assistant Surgeon. To remain on Receiving Ship Vermont until May 15, 1886.

THE TREATMENT OF ASTHMA.—Dr. C. G. Roehr, of Milwaukee, writes that he has successfully treated a number of cases of asthma by means of anti-epileptic remedies. He was led to institute this mode of treatment from observing that most of his asthmatic patients presented a decidedly neurotic history. He asks that others try this method in those cases of chronic asthma in which there is a family history of neurotic affections.

Medical Items.

FRESH PAINT AND ABORTION.—Dr. Llewellyn Eliot, of Washington, D. C., writes: "In the October 31, 1885 number of THE MEDICAL RECORD, Dr. Charles H. French, of Waterbury, requests information on the matter of the odor of fresh paint as a producer of abortions. What the experience of others may be I am unable to state, but my own points very strongly in favor of this as a factor in producing such a misfortune. There are several instances which might be cited in support of this statement. It brings about a 'colica pictonum' with the result indicated. This has been, during the past ten years, illustrated to me in a very forcible manner. Whether the pregnant state renders the patient more subject to the influence of these odors can only be ascertained by the collected evidence of the many, but as one willing to subscribe to this view I record my testimony. It is my practice to discourage pregnant women from moving into newly-painted houses, as well as to deter them from having any painting done in the one in which they live until after the expiration of the gestation." Dr. O. Eugene Larkin, of Deerfield, Wis., November 3, 1885, also writes: "Some weeks ago, I had under observation a primipara in the seventh month, who aborted shortly after moving into a newly painted house. At the time, I attributed it to the improper use of the syringe, although not fully satisfied that that was the cause. Perhaps the odor of paint was a factor in the causation of no small influence."

A NEW HEALTH JOURNAL.—We have received the first number of *Zdrowie* (Health), a monthly journal of hygiene published in Warsaw. It contains several original articles on subjects related to public and private hygiene, and a number of good selections from *The Sanitary Engineer*, and other English, French, and German periodicals. This is the only journal in the Polish provinces devoted exclusively to sanitary matters, and we sincerely hope that its missionary labors in this field will be crowned with success, for it certainly supplies a want long felt.

HEAT AS AN OXYTOXIC.—Dr. J. R. Jones, referring to an article published in this journal, by Dr. Arbery, entitled "Heat as an Oxytoxic," reports in the *Medical Age* a case in which very hot linseed poultices acted successfully in bringing on the pains.

SUING FOR A LARGE FEE.—Dr. Alvarez, a homœopathic physician of Paris, brought suit against the Princess of Medina Cœli for 600,000 francs, for medical services, alleging that he was entitled to more than the usual compensation because of the great wealth of the defendant. The court awarded him 84,000 francs and imposed upon him the cost of trial. The plaintiff was somewhat chagrined, as he had refused an offer of a much larger sum to compromise the suit.

TOO MANY SURGEONS.—Considerable complaint is made by the French journals over the fact that two new hospital surgeons are appointed every year, while no vacancies exist for them to fill. There are at present, it is said, seventeen surgeons with empty appointments, and the number is increasing each year. The journals ask why the authorities do not cease creating new surgeons for a time, until those already on the list have found something to do to justify the title that they hold of hospital surgeons. But the ways of municipal authorities all the world over are past finding out.

CINCHONA RUBRA IN INEBRIETY.—Dr. D'Unger, of Chicago, Ill., wishes us to announce that Dr. Charles Warrington Earle is an untruthful man, because he has said that cinchona rubra is not a cure for inebriety. We should like to oblige Dr. D'Unger, but cannot do so in this case, owing to our belief that Dr. Earle is not the bad man indicated.

Original Articles.

TWO RARE CASES OF ABDOMINAL INJURY.[1]

BY J. A. STUCKY, M.D.,

LEXINGTON, KY.

SURGEON TO ST. JOSEPH'S HOSPITAL; MEMBER KENTUCKY STATE SOCIETY; VICE-PRESIDENT AMERICAN RHINOLOGICAL ASSOCIATION.

I DESIRE to submit the clinical history, as taken from my note-book, of two rare cases of abdominal injury, with recovery in each case. I do so without theorizing or commenting.

CASE I.—On August 4, 1884, at 3 P.M., John C——, Irish, aged thirty-three, while engaged in a bar-room fight received a cut (made with a dirk-blade six inches long) in the abdomen, on right side, extending from the anterior superior spinous process of ilium to just over the symphysis pubis, passing through the abdominal parietes, peritoneum, and almost severing the small intestines in three places. I saw him in a few minutes after receiving the cut. Found him lying on his back on the sawdust-covered floor, the intestines protruding to the extent of six or seven feet and lying on the floor (to his right) in a mass of blood, sawdust, and fecal matter. He had lost considerable blood, but the hemorrhage had about ceased. His body was bathed in profuse clammy perspiration; his expression anxious; pulse, 128. He was given $\frac{1}{4}$ gr. morphine, with $\frac{1}{150}$ gr. atropia, hypodermatically, and $1\frac{1}{2}$ oz. brandy. He swallowed with difficulty. Mental faculties normal. With the assistance of Drs. R. D. Greene and T. L. Patterson, I dressed the wound in the following manner: After placing the protruded intestines in a basin of carbolized water, and thoroughly washing them, a search was made for the wounds from which came the fecal matter. Three wounds were found. The first was almost a complete division of the cylinder of the gut, only a small portion of membrane holding the cut ends together. This served as a guide in inserting the sutures and bringing the edges of wound close together. The second wound, about eight or nine inches from the first, was a transverse incision about three-fourths of an inch long. The third wound, three inches from second, was a longitudinal incision half an inch long. From each fecal matter escaped. These were closed with sutures of carbolized catgut. The abdominal cavity was washed and sponged out as thoroughly as possible under the circumstances, there having escaped into it a quantity of blood and fecal matter. On account of the great amount of intestine protruding, and the protruding portion being much distended by flatus (the patient being intoxicated, and intestines much distended) it was found impossible to reduce it. The external wound was amply large, there being no constriction. Attempts were made to "gently and carefully press the air back in the abdomen." This failing, a number of minute punctures were made with the point of the scalpel to allow the exit of gas. This accomplished, the reduction of the entire mass was easy. The external wound was closed with an uninterrupted silk suture, rubber adhesive strips and abdominal bandage were applied, and the patient removed to St. Joseph's Hospital. At 6.30 P. M. the same evening patient was resting easy; pulse feeble at 126; slight delirium and nausea; temperature, 98⅘°. Gave hypodermic of morphia, gr. $\frac{1}{4}$, and atropia, gr. $\frac{1}{150}$, and ordered 5 grs. of subnitrate of bismuth every four hours. On the following morning he was still resting easy; no nausea or delirium; wound looked well, and as if it might heal by first intention. On the fifth day his bowels acted freely, causing no pain or inconvenience. On the sixth day some ulceration at several points of the sutures was noticed. At these points the suture was cut, which caused the wound to gape, necessitating the bringing of the edges together with long strips of adhesive plaster. The wound continued to gape for about an inch near its lower edge, but filled in rapidly by granulation.

On the ninth day he had slight diarrhœa, due to imprudence in diet, which continued for two days. Subnitrate of bismuth and morphia were given to relieve this. The dressing used in this case was Listerine and water (1 to 12). Cloths wet with this were applied every four hours. Patient was kept on his back and liquid food given. On the seventeenth day he sat up, and in four weeks from the date of the injury he was discharged from the Hospital, having made a good recovery without a bad symptom.

CASE II.—On April 27, 1885, William R——, Irish, aged twenty-eight, brakeman on freight train on Chesapeake & Ohio Railroad, in making a coupling of the engine to the train attempted to raise the draw-bar, so that the coupling-link could enter, when the engine pushing back, the coupling-link struck him, and entered at a point about two and a half inches above the crest of the ilium, one inch to the left of the spinal column, and just below the last rib, passing directly through the abdominal cavity. The point came out about three and a half inches above, and one inch anterior to the anterior-superior spine of the ilium. The link is what is known as the "curved coupling-link," and weighs $17\frac{3}{4}$ pounds, is $5\frac{1}{2}$ inches wide, and 18 inches long. The patient states that he was "pinned or coupled between the engine and car several minutes," and when the engine pulled away from him, he placed one hand over the abdominal wound and the other over the wound in his back, and walked to the caboose, a distance of several cars' lengths, where he was placed on a cot and brought to St. Joseph's Hospital, at Lexington, Ky., a distance of twenty-six miles. He was first seen by Drs. T. L. Patterson and W. O. Sweeny, four hours and thirty minutes after the accident occurred.

On examining him it was found that the muscles of the back and abdomen were greatly lacerated; but a close examination of the intestines, liver, kidney, and stomach revealed no injury whatever. The entire hand and arm was easily pushed through the abdominal cavity, thus enabling a minute examination to be made. The intestines were pushed aside, and no appreciable injury done them. The wound was thoroughly washed with carbolized water, and the edges brought together with deep silk sutures, reinforced by thin strips of adhesive plaster. There was very little shock. Morphia and atropia were administered hypodermatically to relieve pain and secure rest.

The following gives an outline of the treatment pursued, as well as the temperature and pulse, beginning twenty-one hours after reception of injury:

Treatment.—The wound having been dressed so as to favor thorough drainage, the patient being kept on his

[1] Read before the Kentucky State Medical Society, at Crab Orchard, Ky., June 26, 1885.

back, morphia, $\frac{1}{4}$ grain; atropia, $\frac{1}{150}$ grain, given hypodermatically from one to four times a day as required, until the eleventh day. Liquid food—milk, and broths—was the only nourishment allowed. Symptoms of circumscribed peritonitis were noticed on the third day.

The abdomen became distended, tympanitic, and tender; respiration quick and labored; tongue dry. Warm fomentations were used, and tr. digitalis, 15 gtt., and spts. terebinthinæ, 15 gtt., given every fourth hour for thirty-six hours, when the inflammatory symptoms subsided. On the eighth day the sutures began to tear through the tissues, and a large gangrenous slough filled both wounds. Sutures were removed, and poultices of flax-seed and

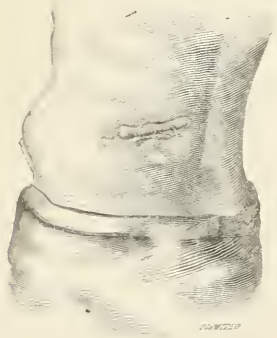

Fig. 1.—Entrance of link.

charcoal applied every four hours. Poultices were continued until the seventeenth day, when the slough had entirely separated, leaving healthy granulating wounds. These were thoroughly covered with iodoform and filled with carbolized oakum; the edges of wounds were brought together as close as possible, with a number of long, narrow adhesive strips. A heavy abdominal bandage was used throughout the entire treatment, to give support and retain the dressing. On the twelfth day a fluctuating tumor was discovered pointing over the junction over the lumbar and sacral vertebræ. A free incision gave exit to a large quantity of pus, after this the wound healed rapidly. Tr. ferri mur., 20 gtt., given every four hours until the sixteenth day, when the dose was reduced to 15 gtt., three times a day. On the thirteenth day chloral hydrate, gr. x., and potas. brom., gr. xx., were given to induce sleep. On the same day patient complained of pain in his bowels; an enema of warm soapsuds was given, resulting in two copious stools. After this the bowels acted daily. Appetite improved, and on the eighteenth day he was allowed to sit up in bed.

From this time no medicine but tr. ferri mur., 15 gtt., three times a day, and potas. brom., at night, was given.

Fig. 2.—Exit of link.

Solid food was allowed, and taken with a relish. The wounds were dressed with iodoform and oakum once or twice daily for several weeks.

Five weeks after reception of injury patient walked to my office, a distance of four blocks, and on the same day was photographed.

The illustrations are made from the photographs. Fig. 1 shows entrance of link, Fig. 2 shows the exit of link, Fig. 3 represents the link.

Remarks.—In Case I. the man was able to go to work (as section-hand on a railroad) seven weeks after receiving the injury. A pad and bandage had to be worn over the

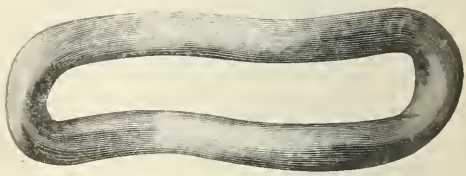

Fig. 3.—Link. Weight. 17¾ pounds; width, 5½ inches; length, 18 inches.

seat of injury on account of a small hernia at point of separation of muscular fibres. Union of the muscles was only partial.

Case II. was able to resume work (as brakeman on freight train) three months after receiving the injury. The union of wound in back was complete, that of abdomen incomplete, and a large hernia is the result. With aid of pad and bandage the man experiences no inconvenience in his work, climbing on top of cars, running, jumping, etc.

At this time, November 1, 1885, both men are in good health.

The Name of Dr. Benjamin Rush, the distinguished physician, patriot, and philanthropist of Philadelphia, has been on tens of thousands of tongues, and in hundreds of public journals during the last few months. Just one hundred years ago he published his celebrated essay on "The Effects of Ardent Spirits upon the Human Body and Mind." It was an elementary treatise, setting forth the pernicious influence of the strongest alcoholic beverages, and recommending "sudden and entire abstinence" from them. In lieu of ardent spirits he recommended coffee, cider, light wines, beer, and such drinks as could be compounded of molasses, vinegar, maple-syrup and water. His essay was republished in England, and one thousand copies of it were presented to the Presbyterian General Assembly in 1811; the good doctor himself visited various religious bodies and commended his views to them; so that he stands also as the pioneer temperance lecturer.—Dr. Theodore L. Cuyler.

CASE OF CÆSAREAN SECTION AFTER DEATH OF MOTHER.—SUCCESSFUL.

By J. MACK HAYS, M.D.,

OXFORD, N. C.

A SHORT while after eight o'clock on the evening of October 3d, I was hastily summoned to the wife of Mr. C——, living seven miles distant. On reaching the house I was informed that the patient was too far gone for me to do her any good. The following history was briefly given me: About four hours previously Mrs. C—— was in the yard looking after her domestic affairs, and enjoying, apparently, her ordinary good health, when she was suddenly attacked with a violent headache and sent in haste for her husband, at the mill, a hundred yards distant. When he reached the house she told him to send at once for the doctor, as she felt very sick, and her head hurt her terribly; then throwing her hands to the back of her head, fell on the bed with the exclamation, "I can't stand it!"

She was speechless from that moment, vomited frequently for some little time, several times threw her left hand to her head, and sank rapidly into the condition in which I found her. She was evidently suffering from an extensive cerebral apoplexy, presenting the following symptoms: Complete motor and sensory paralysis of left side of body; both pupils widely dilated and totally insensible to a bright light; very slow, stertorous breathing, and "drawing in of the paralyzed cheek with inspiration, and its puffing out with a sort of explosion in expiration;" pulse rapid and barely perceptible; face pallid. A sharp pinch on the non-paralyzed arm produced no evidence of sensation, nor did the hypodermics of whiskey which I administered as a forlorn hope. The patient was rapidly approaching her end, and was eight and one-half months advanced in pregnancy.

I satisfied myself from the husband that the child was probably alive, as he had heard his wife speak of having felt quickening the same day. I then laid the case clearly before the husband, telling him that while one life was fast passing away, another was at stake which might be saved even after the mother had breathed her last. He told me to do as I thought best. Accordingly I made the necessary preparations, and after all evidences of life had disappeared in the mother, and the bystanders sent out of the room, I proceeded without delay with the operation. With one stroke of my scalpel I incised the skin and subcutaneous tissues from the umbilicus nearly to the symphysis pubis; two incisions more, through the linea alba and peritoneum, exposed the uterus to full view; through it I next made an opening as low down as possible, and of sufficient size to admit my two fingers, at the same time liberating the liquor amnii. Using my fingers as a director I slit up the uterus to the placenta, which I easily detected. The body of the child was now fully exposed, lying in the second cranial position. I lifted it from the uterus, and by exerting some little force to overcome the suction brought to bear upon the head, removed a living male child from its dead mother. The cord was tied and cut as usual. The operation was attended with a very slight loss of blood, and that of a dark venous character.

The unusual shape of the child's head, born without any pressure having been exerted upon it, was quite noticeable.

The child is being fed on fresh cow's milk, diluted and sweetened, and at the present writing, October 15th, stands a fair chance of being raised. It makes the fourteenth child born of Mrs. C——, all of whom are living.

I will not inflict upon the reader any remarks upon the foregoing case, nor will I undertake at this time to give a *résumé* of previous operations of a similar nature, but would refer all who may be interested in the literature of the subject to the *American Journal of the Medical Sciences*, October, 1879; *American Journal of Obstetrics*, January, 1879; *Wiener Medical Wochenschrift*, No. 22, 1879; *British Medical Journal*, June 14, 1879; and to the *Index Medicus*, for more recent cases.

My thanks are due Dr. R. P. Harris, of Philadelphia, for kindly directing me in my search after statistics, etc., bearing upon my case.

BRIGHT'S DISEASE OF THE KIDNEYS.[1]

By R. C. M. PAGE, M.D.,

INSTRUCTOR IN DISEASES OF THE HEART AND LUNGS AND GENERAL MEDICINE, NEW YORK POLYCLINIC.

DR. RICHARD BRIGHT, of Guy's Hospital, London, first established the fact that albuminuria and dropsy coexisted with renal disease. That occurred in 1827. Since that time the subject has received such universal attention from the medical profession, and is so well known even to the laity, that the term Bright's disease has become a household expression.

Without entering upon the various classifications proposed by different authors, suffice it to say that the disease may be acute or chronic; the latter sometimes resulting from the former, or, more frequently, being chronic from the first. Whatever be the ultimate pathological result, all forms of the disease, except perhaps waxy degeneration, appear to be of an inflammatory nature at the outset. Both kidneys are attacked, and one portion of a kidney may be affected differently from another part of the same organ.

Acute Bright's disease (acute tubal or tubular, parenchymatous, desquamative, catarrhal, croupous, diffuse nephritis, inflammatory dropsy) usually has a well-defined outbreak and a cause not difficult to ascertain. Whatever the predisposition may be, exposure to cold and wet are frequently exciting causes. In these cases the inflammation is usually diffuse. Abuse of alcoholic beverages and exposure incident to intoxication may produce it. Other toxic agents which cause the disease when taken internally are copaiba, turpentine, cantharides, the mineral acids, phosphorus, arsenic, nitrate of silver, lead, and mercury. Sometimes, as is well known, it follows scarlet fever in children. In these cases the inflammation is usually limited to the tubules of the cortical substance, although in severe cases it may extend to the intertubular tissue here and there in spots. Or, coincidently, the child may also have diffuse nephritis from cold, especially during desquamation. Sometimes also it follows diphtheria and epidemic cholera. Occasionally it is developed in the course of measles, and, according to Flint ("Practice," fifth ed., p. 868), in pulmonary tuberculosis, articular rheumatism, typhoid and typhus fever, erysipelas, relapsing fever, acute lobar pneumonia, pyæmia, septicæmia, endocarditis, dysentery, carbuncles, and suppurative processes. Extensive burns are also mentioned by the same author as a cause.

In some cases pregnancy appears to favor the production of the disease, if indeed it does not actually cause it. According to Bartholow ("Practice," p. 482) it occurs not oftener than once in one hundred and fifty pregnancies. It is probable, therefore, that a predisposition exists in these cases, pregnancy being merely the exciting cause. According to the same author it occurs usually in primiparæ, and is more common in twin pregnancies. This accords with my own observations.

All persons are subject to the disease, but it occurs more frequently among children and those under middle life. Men are said to be more subject to it than women, and it occurs sometimes among those who were apparently in previously robust health.

Dropsy is usually the first symptom that causes the patient to seek medical advice. It is probably due to loss of albumen, thus allowing the watery portion of the blood to transude more readily, aided, in some cases, by pressure due to diminished excretion of water by the

[1] Read before the Section of Practice of Medicine, New York Academy of Medicine, November 17, 1885.

kidneys, and the anæmic condition of the patient. Along with this there are pallor of the face, and more or less uræmic symptoms, such as drowsiness, headache, nausea or vomiting, paroxysmal attacks of dyspnœa, temporary disturbance of vision, and the like. These are all readily described by the patient, or those in attendance, without even waiting to be questioned. Upon investigation, however, it will usually be found that, a short time previously, there were chilly sensations, or a distinct chill, followed by more or less febrile excitement. Pain in the back, unless associated with lumbago, is usually absent, but there may be tenderness under firm pressure.

The urine is scant and high-colored, sometimes smoky or even bloody. The specific gravity is higher than normal, sometimes going up to 1.030, or even 1.065 (Roberts), and is loaded with albumen. It contains epithelial casts usually, but there may be also blood and hyaline casts.

The presence of albumen in the urine is probably due to its transudation through the walls of the renal capillaries from increased tension. If rupture occurs, blood also will be found. After structural changes have taken place the albuminuria will continue. According to Cohnheim, however, the albuminuria is due to changes in the epithelium of the glomeruli.

Albumen appears in the urine transiently, and in moderate quantity, in connection with other conditions than Bright's disease. It sometimes occurs in the course of dyspepsia, as in a case that came under my charge five years ago. Dr. Francis Delafield critically examined the urine, and Dr. Alonzo Clark, being called in consultation, confirmed the diagnosis of dyspepsia. The patient completely recovered. The albuminuria was probably due in this case to nervous depression, attended with temporary vaso-motor paralysis and dilatation of the renal capillaries. Occasionally albumen is found in the urine of soldiers after exhausting marches, and athletes, and is probably due to the same cause. Such cases accord with Runeberg's theory of diminished pressure.

There is no possibility of mistaking albumen in the urine for anything else, if the heat and nitric-acid tests be used with proper care. Even in those cases where there is only a trace of albumen, Heller's test is the best. Peptones, and all derivatives of albumen, and vegetable alkaloids, clear up under heat. If Heller's test, therefore, gives a film which remains under heat, it is albumen. Moreover, peptones and the like are of little or no clinical significance, except as indicating dyspepsia. If resinous substances are suspected, alcohol should be added to dissolve them. This occurred several years ago at Professor E. D. Hudson's clinic, where urine had been brought in a vial containing some resinous liniment.

In unfavorable cases œdema of the lungs may occur, also secondary inflammations of serous membranes and the lungs, but these are far more frequent in the chronic form.

Besides the uræmic symptoms already mentioned, there may be convulsions and coma. The cause of these symptoms is also a matter of dispute. The most commonly received opinion has been that they were due to urea retained in the blood. Frerichs believed that the urea was converted into ammonium carbonate by decomposition from the action of a ferment in the blood. This theory, according to Loomis ("Practice," p. 538), has been disproved. According to Oppler, Zalesky, and others, the uræmic phenomena are due to the retention in the blood and tissues of creatine, creatinine, and other extractives, the urea and uric acid being formed by the kidneys themselves, and present in the blood by absorption. On the other hand, Traube considers that the so-called uræmic symptoms depend upon œdema of the brain and cerebral anæmia. Niemeyer (vol. ii., p. 29, Am. trans. eighth Germ. ed., 1881) goes so far as to discriminate between symptoms due to uræmia, and those dependent upon such œdema. Other causes, including cerebral lesions, have been advocated by different authors.

In favorable cases the patient usually recovers in about six weeks. Roberts mentions a case that completely recovered in ten days. The patient may also recover after several months or more.

The diagnosis is usually simple, and the prognosis nearly always favorable, especially if the patient is seen early. According to Roberts, the prognosis is more favorable in the aged than in the young. With others it is just the reverse. The longer the albuminuria continues, the more unfavorable the prognosis, and recovery cannot be said to be complete until it has entirely disappeared.

Regarding treatment, authors prudently recommend that the patient be kept warm in-doors, and in bed, if necessary, and among other means, diaphoretics. Of these I would prefer the hot-air bath or other mechanical means to the administration of drugs, except in the case of marked uræmic poisoning, as will be noticed hereafter. Cups to the loins, with or without scarification, and hot fomentations, are also recommended. Of the two I prefer hot poultices, as they are more comfortable to the patient, and are, I believe, equally efficacious. Unless properly applied and kept hot, however, they are a delusion.

All these means may be employed, it is true, but in the last six cases treated by me at the Northwestern Dispensary, in this city, I have found them unnecessary. The patients were from puberty to thirty-two years of age, and walked to the dispensary for treatment. In all, dropsy was a prominent symptom. One of them, a lad eighteen years of age, was so disfigured by swelling that his most intimate acquaintances could scarcely identify him.

The question naturally arises, Shall we give diuretics? and if so, at what stage of the disease? In cases of tubal nephritis, as is usual when the disease is caused by the infection of scarlatina, I have found that the diuretic treatment alone is sufficient to effect a speedy and complete cure. The diuretic employed is the one recommended by J. Hughes Bennett (potass. acetat., ʒ ij.; spts. ether nitrosi, ℥ ss.; aquæ ad ℥ ij.; sig. ʒ j. t.i.d.)

But in cases of acute diffuse nephritis, as usually occurs among adults from exposure to cold, we have a more serious pathological condition to deal with. The tubules are not merely obstructed with epithelium that may be easily washed out by diuretics, they are effectually blocked by epithelium and exudatory matter within, and without by pressure from interstitial inflammatory products. According to Recklinghausen, the white corpuscles of the blood play an important part in separating the epithelium from the inner surface of the tubules. In this condition I doubt if diuretics are indicated. I prefer to wait until the more acute symptoms have subsided before their positive administration, their use being simply to wash out the tubules.

The first thing I do in such cases is to administer a hydragogue cathartic. It unloads the bowels, relieves pressure on the kidneys, and lessens inflammatory action in those organs, thus preparing the way for diuretics.

After a fair trial in one hundred and seventy-five cases of œdema and general dropsy at the Northwestern Dispensary, assisted by Dr. J. C. Mackenzie, pulvis purgans (pulv. jalap. co.) was found to be more certain and uniform in its action, and better for general use than elaterium, although the latter was obtained from some of our leading drug stores. Elaterium may be invaluable, however, in uræmic coma, owing to its rapidity of action sometimes, and the facility with which it may be given. A drachm of the pulvis purgans may be given, and the dose repeated if necessary.

Deterioration of the blood occurs early, and I usually give twenty drops tr. ferri chloridi in water, every three hours, from the start. According to Roberts, iron acts very beneficially, and hastens in a marked manner the disappearance of blood and albumen from the urine. But he suggests that, when begun too early iron is apt to induce a return of the acute symptoms. On the contrary, where

I have given iron from the first, I have not observed any such effect.

After about a week, when the more acute symptoms have subsided, I combine the iron with tr. digitalis and a bitter tonic (cinchonid. sulph., ʒj.; tr. ferri chloridi, tr. digitalis, āā ʒij.; aquæ ad ℥ij. Sig. ʒj. t.i.d.). A good milk diet is indispensable. In all my cases the milk was furnished by the New York Diet Kitchen for the Sick Poor.

Should uræmic symptoms become urgent, or convulsions occur, I prefer the hypodermic morphine treatment, as advocated by Loomis (op. cit., p. 542), to the administration of chloroform. Both chloroform and ether may fatally depress the heart, which sometimes acts as it does in shock. It would be interesting here to inquire whether or not renal disease has any bearing on the cause of death that sometimes occurs during the administration of chloroform and ether for surgical operations. The morphine may be given first, and other means employed afterward. In a limited number of cases, however, I have given morphine and pilocarpin together hypodermically, with good results. A grain of muriate of pilocarpin is dissolved in eighty minims Magendie's sol. morph., of which ten minims are injected. The morphine sustains the heart and allays nervous excitement and dyspnœa, while the pilocarpin materially aids in eliminating the poison through the skin. Both indications are thus met at once. The morphine alone may be repeated if necessary, or given in larger doses at first, but great care should be taken not to give large doses of pilocarpin, owing to its depressing effect on the heart.

In the autumn of 1883, I first gave morphine and pilocarpin combined. The case was a boy, aged fifteen years, with a severe attack of bilious remittent fever, and was seen with me by Dr. H. Koplik, of this city. In spite of large doses of quinine the temperature rose to 105° F., the urine became almost suppressed, bloody, and highly albuminous, and the patient delirious, partly from fever, and partly, as I thought, from uræmic poisoning. In less than half an hour after the injection he was bathed in a profuse perspiration, and soon became conscious. The quinine was pushed, and the patient entirely recovered within a week. Should coma occur, elaterium alone, or in conjunction with other means, may be sufficient, as occurred in a case at Bellevue Hospital seventeen years ago. By order of Dr. Austin Flint, Sr., I gave the patient, who was a man about thirty-five years, two grs. of Clutterbuck's elaterium. He was made to swallow by manipulating the larynx, but it may also be given with a tube. The remedy proved successful and the patient left the hospital afterward, much improved, though not cured.

After a complete cure of acute Bright's disease, the patient should be made to understand that care must be taken for a long time not to bring on a relapse by acts of imprudence. Temperate habits, and comfortable, but not too warm, clothing are necessary.

Chronic Bright's disease may assume one of three typical forms, according to the renal elements affected. 1. The tubules. 2. The interstitial tissue. 3. The blood-vessels. Or there may be, and generally are, mixed cases in which all these anatomical elements become more or less involved.

1. Chronic tubular (parenchymatous) nephritis may result from one or more acute attacks, or generally it is chronic from the first. The kidney is large, smooth, and white, the changes occurring chiefly in the cortical portion; or it may subsequently undergo collapse from disintegration of the tubal elements and become smaller than normal. The etiology in general is the same as that of the acute disease, but is often obscure. It may occur at any age, in both sexes. The symptoms are more marked than in any other form, dropsy being prominent and the face pale and puffy. There is also more liability to secondary inflammations of serous membranes, and uræmic symptoms. The urine is scant, above normal sp. gr., and high colored. It is loaded with albumen and contains fatty and hyaline casts. Dyspnœa, besides paroxysmal uræmic attacks, sometimes occurs, due to œdema of the lungs, or other intercurrent affection of the organs of respiration or heart. Besides temporary disturbance of vision due to uræmia, there may occur neuro-retinitis, to be detected by the ophthalmoscope. Cardiac hypertrophy, with or without valvular lesions, sometimes occurs. The valvular lesions may be due to some previous disease, or developed during the renal affection. Simple hypertrophy of the left ventricle without valvular lesion may exist, but it is more frequent in connection with cirrhotic kidney.

2. Chronic interstitial nephritis is productive of the cirrhotic kidney. The organ is red and smaller than normal, due to shrinkage of the cortical portion, and also the tissue between the pyramids. The disease is chronic from the first, and occurs usually in men past middle life. It is caused by habitual intemperance, gout, rheumatism, syphilis, chronic lead-poisoning, and the like. Often the etiology is obscure or unknown. It begins insidiously, and may have existed months before detection. There is generally little or no dropsy. A slight fulness under the eyes (called *pods* by the laity), and, perhaps, about the ankles, may be all that the closest inspection can reveal.

The urine is abundant, pale, and of a lower specific gravity than normal. It contains but little albumen, and at times may be entirely free from it. The casts are hyaline and granular. From a fit of intemperance, or other cause, acute tubular nephritis may supervene with its usual symptoms, notably dropsy and albuminuria.

Simple hypertrophy of the left ventricle, without valvular lesion or degeneration of muscular fibre, often occurs in this form. According to Traube, it is owing to increased resistance to the renal circulation, but Bartholow (p. 496) and others consider additional obstruction in the arterioles throughout the body due to hypertrophy of their muscular layer. Neuro-retinitis, apoplexy of the retina, and even of the brain, may occur in this form.

3. Lastly, we have waxy (lardaceous, amyloid) degeneration of the kidney. The afferent vessels of the glomeruli are primarily affected, and it is secondary to some other pre-existing wasting disease, as caries, phthisis, syphilis, and the like. I have observed it mostly in connection with the last stages of pulmonary consumption. Parenchymatous nephritis usually supervenes, and it is attended with more or less dropsy.

Regarding treatment, little or nothing can be done in case of waxy kidney. In chronic tubular (parenchymatous) nephritis, treating symptoms may become necessary, a general outline of which was given in the acute disease. Pricking the skin for the relief of dropsy is not to be thought of, and bandaging may contribute to œdema of the lung, as in a fatal case reported by Dr. D. H. Stewart, of this city. The repeated use of pilocarpin as a curative agent has not, in my experience, been justified by results. As a temporary makeshift for uræmic poisoning, when combined with morphine, I believe it worthy of further trial. In cirrhotic kidney, if the patient had syphilis, potassium iodide, with or without the mercuric chloride, or, in case of chronic plumbism, the potassium iodide alone may be given. In a number of cases I have given small doses of the mercuric chloride in some bitter tonic, after the plan in vogue at the old New York Hospital, 1867–68, but without permanent benefit. Iron and bark, with or without digitalis, are recommended. Paroxysms of uræmic dyspnœa, occurring in any form of the disease, may be relieved by hypodermic injections of morphine, as I witnessed at Bellevue Hospital, 1868, in Dr. Loomis' service. The diet should be nutritive, consisting largely of milk. Clothing should be comfortably warm, and the patient should winter, if possible, in a warm, dry climate. With the best treat-

ment, however, and every precaution, although the patient's condition may be improved and life prolonged, the tubular (parenchymatous) form of chronic Bright's disease is the only one ever cured, I believe, and even here recovery is very rare.

31 West Thirty-third Street, November, 15, 1885.

A CASE OF ACUTE GENERAL TUBERCULOSIS DIAGNOSTICATED, DURING LIFE, BY THE PRESENCE OF TUBERCLE BACILLI IN THE SPUTUM.[1]

By EUGENE HODENPYL, M.D.,

HOUSE PHYSICIAN, ST. FRANCIS HOSPITAL, NEW YORK.

Joseph K——, aged thirty-five, a truck driver, was admitted into the St. Francis Hospital, New York, March 16, 1885. His family and previous history were good. Was a moderate drinker; had gonorrhœa once; no evidence of syphilis. Patient stated that two weeks before admission he developed, without apparent cause, a moderate cough, at first without expectoration, accompanied with fever, loss of appetite, and exhaustion.

On admission the rectal temperature was $104\frac{4}{5}$° F.; pulse, 100, and somewhat feeble; urine normal. He had a slight cough, and occasionally expectorated a small quantity of tenacious mucus. He was very apathetic, and the expression of his face was dull and stupid.

Physical examination revealed a moderate degree of bronchitis, most marked posteriorly. The liver was somewhat tender on pressure, and the spleen was slightly enlarged. The bowels were regular until the last few days of the disease, when there was diarrhœa with incontinence of urine and fæces. While in the hospital, his temperature was extremely irregular, varying from 100° to 106° F. At no time did he complain of pain. His bronchitis remained moderate. The apathy gradually merged into coma, which was complete at the time of his death, April 16th.

On April 3d a small quantity of the expectoration was obtained, with difficulty, and was found to contain tubercle bacilli in moderate numbers. A diagnosis was then made, based first upon the presence of tubercle bacilli in the sputum of the patient who gave no indications of phthisis. Secondly upon the very indefinite character of the clinical symptoms.

Autopsy.—Brain and meninges normal. Heart smaller than normal in proportion to the size of the body, and in the cardiac muscle were several miliary tubercles. Lungs: There was a catarrhal inflammation of the smaller and medium-sized bronchi. Scattered throughout both lungs were an enormous number of rather small, sharply outlined miliary tubercles. In the apex of the right lung was a nodule about the size of a walnut, apparently composed of dense connective tissue.

The bronchial glands were enlarged and the seat of a tubercular inflammation. Portions of them were in a condition of cheesy degeneration, forming semi-fluid masses. The liver, kidneys, diaphragm, and omentum contained miliary tubercles; also the spleen, which was enlarged and soft.

Microscopical examination.—The tubercles in the lungs are irregular in shape and frequently merge into one another. Microscopically, they consist in general of groups of air-vesicles and smaller bronchi, whose outlines are still fairly distinct, and are filled in part with tubercle tissue, and in part with a dense structureless, cheesy material. The air-vesicles in the periphery of the nodules show desquamation and proliferation of the vesicular epithelium. So abundant are the tubercles, and so extensive the peripheral inflammation, that on section of the lungs somewhat more than one-half the air space is solidified. Giant cells appear to be entirely absent from these pulmonary tubercles. Tubercle bacilli were present in very large numbers. These tubercles, as will be seen from the above description, are similar to the miliary tubercles frequently found in the lungs of children, and which usually contain great numbers of tubercle bacilli. In children they are sometimes called pneumonic tubercles. Microscopically, the tubercles in the other internal organs presented no morphological features worthy of remark.

Remarks.—The difficulty of diagnosis in cases of acute general tuberculosis is so great, that at the time of Koch's announcement of the discovery of the tubercle bacillus, it was hoped that in this disease, as in phthisis, examination of the sputa might furnish us with a definite means of diagnosis. Thus far, however, the examinations of sputum which have been made in this disease have given negative results, no tubercle bacilli being found. Recourse was accordingly had to examinations of the blood[1] from the spleen, removed by puncture. This procedure has proven successful.

The above case seems worthy of record, because examination of the sputum did show tubercle bacilli and upon the result a diagnosis was possible. The recorded cases are too few to enable us to say whether this result is exceptional or not; for the difficulty of obtaining suitable sputum, and the short duration of the disease, together with the uncertainty which always exists in examinations for tubercle bacilli when they cannot be repeated in case of failure, would readily explain negative results.

It should be borne in mind as possibly bearing upon this case that the tubercles in the lungs were not of the type usually found in adults, but were loose in texture, exceedingly abundant, intimately connected with the bronchi and contained unusual numbers of tubercle bacilli. In regard to the source of immediate infection, it was undetermined, as unfortunately the vessels at the bases of the lungs (pulmonary veins and thoracic duct) were not examined, but the tubercular bronchial glands furnished conditions which, according to the researches of Weigert[2] would serve as a focus of infection.

In whatever relation the above-mentioned nodule of connective tissue at the apex of the right lung may have stood to the present acute disease, its firm, dense character, and the absence of any other phthisical process whatever in the lungs, would seem to preclude the possibility of the bacilli coming from any other source than the acute lesion.

43 Seventh Avenue, Brooklyn, N. Y.

Preventive Inoculation by a Russian Priest.—A Siberian journal states that in 1868, when the plague was killing all the cattle in the country, Father Andrew Joakimansky, of the Troitzky village, resorted to a desperate means in order to save his cows. He got some blood from a dying cow, saturated threads with that blood, and passed these threads through the ears of the healthy cows, numbering eleven. At the place where the ears were punctured there appeared tumors of the size of pigeon eggs. In a short time these tumors disappeared, and the cows remained alive and healthy, though the rest of the cattle of that village perished.

The French Association for the Advancement of Science.—The next meeting of this Association will be held in 1886, at Nancy. The session will be presided over by M. Friedel, the vice-president of the Grenoble meeting. Dr. Rochard has been elected vice-president for 1886.

Clinical Department.

TEETH IN A NEW-BORN CHILD.

Dr. T. A. O'Callaghan, of Worcester, Mass., writes that Mrs. H—— gave birth in January last, to her seventh child, a large healthy boy. Pain on nursing suggested to the mother an examination of her child's mouth, when she discovered the two lower incisors protruding from the jaw fully one-sixteenth of an inch. These two teeth still remain, are perfectly sound, and differ in no way from their companions which have since appeared, except that they are larger.

COCAINE IN HAY FEVER.

Dr. W. Cheatham, of the University of Louisville, Ky., writes that he has had quite an extensive experience in this direction during the past summer, and has been well satisfied with the results obtained. Nearly all the head symptoms are relieved by applying a cocaine solution to the anterior two-thirds of the nasal cavities, and in the few cases in which the itching and discomfort about the eyes still remain, they are relieved by occasionally dropping the solution on the conjunctiva. In this case, since cocaine dilates the pupil and affects somewhat the accommodation, eserine sulphate may be added in the proportion of $\frac{1}{100}$ grain to a drachm of the four per cent. solution, or $\frac{1}{200}$ grain to the same amount of a two per cent. solution. The asthma is readily and entirely relieved by making an application to the posterior ends of the inferior turbinated bones, to the pharynx, and in some cases to the larynx also. These two sensitive areas, Dr. Cheatham says, have not, as far as he knows, been noticed by writers on the subject, but he has found that the pharynx is implicated in most cases, and the larynx in a few. In applying the drug to the nose a piece of absorbent cotton, large enough to reach to the posterior extremity of the inferior turbinated bones, and to fill comfortably the middle meatus, is wet with the solution, introduced and allowed to remain about twenty minutes. In some cases, however, in addition to this and dropping into the eye, applications must be made to the soft palate, pharynx, and occasionally to the larynx, in order to reach the several sensitive areas and control the asthma. Dr. Cheatham relates several illustrative cases in which confirmed hay fever subjects were relieved of all their distressing symptoms by cocaine. In several young patients great comfort was obtained by the use of a strong infusion of coca leaves in an atomizer. Boroglyceride was added in the proportion of one ounce to the pint of infusion in order to preserve it. The writer concludes by expressing the belief that many, probably the majority, of hay fever sufferers can remain at home without any marked discomfort, if taught to use cocaine properly. And most of the remainder can also do so by submitting to active treatment designed to correct the nasal hypertrophy, deflected septum, polypus, or other affection to which many of them are subject. The best treatment for these conditions is cauterization by chromic acid, the galvano, or the actual cautery.

THE ANTIPHLOGISTIC ACTION OF MENTHOL.

Dr. Selwyn A. Russell, of Albany, N. Y., writes to call attention to the use of menthol as an antiphlogistic and anodyne remedy in superficial inflammations, in which, he says, its effects are truly remarkable. "My discovery of its value in such conditions was quite accidental; a patient who was suffering from acute aural perichondritis, failing to obtain relief from the usual anodyne applications, bethought himself of menthol which he applied by means of the ordinary pencil; the relief from pain was immediate, and from that time, to my surprise, the inflammation quickly subsided. I have since made frequent use of it, and I believe inflammations have aborted which, without it, would have ended in abscess; and in addition the pain, itching, heat, and swelling have been considerably reduced. I have used the ethereal solution (alcohol is also a good solvent) in the strength of from ten to fifty per cent., applying it by means of a camel's-hair pencil. The applications may be made two or three times a day, or more or less frequently according to the indications. A solution in one of the fixed oils may be used on mucous membranes. I have observed the good effects of menthol more especially in boils, carbuncles, excessive inflammation following vaccination, etc. The employment of this substance in superficial neuralgias, for its anodyne effect alone, is often very satisfactory, but its use in this way has been noticed and written upon by others."

COCAINE IN OPERATIONS ON THE PREPUCE.

Dr. Charles Graefe, of Sandusky, O., writes: "Apropos of Dr. Bruce's article in The Record of October 31st, I should like to describe a case I had last March. A young man came to my office desiring relief from a phimosis, and as the foreskin was not much lengthened, though constricted, I decided to operate after Roser's method of incision. Preparatory to the operation, I rubbed a five per cent. solution of oleate of cocaine, and during the time it took to get my instruments and thread my needles, I had the patient hold a small piece of cotton saturated with the same solution along the proposed line of incision. During the operation, which was completed in about ten minutes, the patient experienced no pain, and even held the cutaneous and mucous layers together while I sewed them. He afterward said that he experienced more during the removal of the sutures than he did when they were put in."

ABNORMAL MOBILITY OF THE TONGUE.

Dr. T. F. C. Van Allen, of Albany, N. Y., reports another case of the above. S. A——, now a practising physician, was a student at the time when he kindly permitted me to examine his fauces. He had never suffered from more than an occasional "sore throat," nor had he ever developed the mobility of his tongue by practice. The tongue, fauces, and palate appeared to be perfectly normal. He could with perfect ease place the tip of his tongue into the naso-pharyngeal space, and apply it to the openings of the Eustachian tubes, to the vomer, and turbinated bones.

RESECTION OF THE ANKLE-JOINT.

Dr. C. S. Van Riper, of Paterson, N. J., reports the following case of resection of the ankle. The patient, a German woman, thirty years of age, was admitted to St. Joseph's Hospital, suffering from disease of the ankle-joint. She stated that one afternoon, some twelve weeks previously, she had experienced a dull, aching pain in the heel for a time. This pain came and went for a few days, and finally became persistent, and was accompanied with swelling. Both ankles were affected at first, but after a time the trouble appeared to centre on the left side. On admission to hospital, the ankle was found much inflamed, having a brawny appearance, and presenting a point of fluctuation over the external malleolus. A diagnosis was made of fungous arthritis, and it was decided to resect the joint. An incision was made on either side, from a point about two inches above the end of the malleolus downward over this process and on the side of the foot, in a curved line, to about two inches below the tip of the malleolus. The lateral ligaments

were divided, and then, the posterior tibial artery and the tendons of the flexor longus digitorum and tibialis posticus being protected by a retractor, the internal malleolus was divided by bone-forceps, and removed. The foot was then firmly grasped by the hand, and luxated toward the inner side, exposing the articular surface of the tibia and the external malleolus. A thin layer of bone from this surface was removed by the saw, and the diseased portion of the astragalus gouged away. The foot was replaced, and, a decalcified bone drainage-tube being inserted, the wound was closed by interrupted sutures. The foot was then immobilized by means of a splint, consisting of galvanized iron foot- and leg-pieces, joined by a stout iron bar, curved so as to permit of the application of the dressing to the wound. The splint, being well padded with felt, was attached to the foot and leg by a plaster-of-Paris bandage. When this had become firm, the wound was syringed out with a sublimate solution of the strength of one to three thousand, dusted with iodoform, and enveloped in an antiseptic dressing, and the limb suspended from a horizontal bar passing over the foot of the bed. The dressings were changed every eighth day, and at the end of two months the wound was entirely healed, and the patient allowed to leave the bed, the ankle being protected by lateral supports attached to the shoe. The operator was assisted during the operation and in the after-management of the case by Dr. Carroll, the house-physician to St. Joseph's Hospital, to whom he desires to acknowledge his indebtedness. The patient is now able to attend to her work in the mill, but uses a cane when walking in the street, as she is afraid of stumbling. The removal of the internal malleolus, and luxation of the foot, the writer says, render the operation more easy of performance, and reduce the risk of injury to the posterior tibial artery to a minimum, since this vessel is not put on the stretch.

Progress of Medical Science.

The Use of Carbonate of Ammonia in Cerebral Hemorrhage, Thrombosis, and Embolism.—Dr. R. C. Van Wyck, in *Gaillard's Medical Journal*, claims the following advantages for the carbonate of ammonia in the treatment of cerebral hemorrhage, thrombosis, and embolism: 1. As a diffusible stimulant to the general circulation, relieving the anæmia which is present in the brain, increasing the cutaneous circulation, and inducing perspiration—relieving in this way intercranial pressure. 2. By its direct action in dissolving the clot. The only agents which possess this property are the alkalies, and the most effective of these is ammonia. 3. In œdema and congestion of the lungs, so often seen in apoplexy, the use of this salt will often relieve the existing condition, partly by its stimulating action on the terminal capillaries, and also by its expectorant action on the broncho-mucous membrane. 4. By keeping up the alkalinity of the blood, and preventing further thrombosis. I do not claim this drug as a specific, but only an auxiliary to other remedies. In the treatment of a case of cerebral hemorrhage, the following would seem to me the order of treatment: 1. The prodromal symptoms which threaten an attack of apoplexy, by prompt venesection and catharsis. 2. To relieve the period of reaction, after paralysis has taken place, by arterial sedatives, preferably aconite. 3. To remove the exudation and all retrograde changes in the clot, anæmia, pulmonary congestion, and further thrombosis, by the free use of carbonate of ammonia. 4. To support the system by nourishing yet unstimulating diet, and by the use of medicines which nourish the brain tissue, such as syr. lacto-phosphate of lime, cod-liver oil, and the phosphide of zinc. 5. To increase the muscular development by massage-frictions, electricity, and strychnia. The carbonate of ammonia should never be given in cerebral hemorrhage until the period of reaction has fully taken place, say from ten days to two weeks. It should then be given continually for at least a month or more, or until the retrograde changes in the clot are accomplished. In thrombosis and embolism, if the diagnosis can be clearly made, it should be given at once. The dose used was five grs. three times daily in ʒ ss. of the solution liquor ammoniæ acetatis. There is one class of cases in which the carbonate of ammonia has not acted well in my hands, viz., cerebral hemorrhage associated with interstitial nephritis and hepatitis. In these cases I have had good results from the phosphate of sodium twenty to thirty grains, three times daily in the infusion of dandelion, given after meals, and small doses of corrosive sublimate, $\frac{1}{24}$ gr. three times daily before each meal. I have sometimes combined it in a pill with digitalis and squill.

Ready Method of Applying Dressings to the Perineum.—In *The Lancet*, October 3, 1885, Dr. Laffan draws attention to a ready method of applying dressings to the perineum. His advice is as follows: Take an ordinary elastic cricket-belt. Buckle it round the waist next the skin. Any handkerchief tied before and behind passing between the legs will furnish a perineal bandage, for which he claims the following advantages: The belt, being elastic, yields readily to any strain, and thus accommodates itself to all changes of posture, without altering the position of the handkerchief with reference to the part whereon the dressing is applied. It is to be found in almost every house; it is easily adjusted; and it does not in any way interfere with locomotion, or with the free movement of the abdominal muscles.

The Etiology of Asthma.—The dependence of some forms of spasmodic asthma upon the presence of nasal polypi or other morbid conditions of the naso-pharyngeal tract, has been of late much discussed in Germany. A wider view is that taken by Dr. Schadewaldt, who declares that for some years past he has been convinced that genuine spasmodic asthma is due to reflex excitation from a hyper-sensitive nasal mucous membrane, whether there be any anatomical change visible or not (*The Lancet*, October 3, 1885). If this conception of asthma as a "nasal trigeminal neurosis" be held, so that the sphenopalatine ganglion is regarded as the special asthma centre, he thinks that a sufficient explanation is given of the violent phenomena of the paroxysms. In severe attacks an excessive degree of reflex excitability may be overlooked; and it must be borne in mind that a hysterical temperament especially favors asthma. He further thinks that if this doctrine be accepted, an advance may be made in the treatment of asthma, and is surprised that the nasal symptoms characteristic of the affection have been so long disregarded. Upon this we would remark that undoubtedly in some cases true spasmodic asthma is preceded by, or the paroxysms alternate with, violent attacks of sneezing; but, on the other hand, there is often no pronounced disposition to bronchial asthma (at least in its well-marked and severe form) evinced by the sufferers from "hay asthma," which must surely be regarded as a marked instance of "trigeminal neurosis." Dr. Schadewaldt, however, adduces other arguments in support of his view, and indicates a method of diagnosis by excitation of the nasal branches of the fifth by means of the nasal sound. He asserts that fumigation of belladonna or stramonium leaves soaked in strong solution of nitre forms the best means of calming the asthmatic paroxysm, and is far better than smoking, unless the fumes are inhaled into the nostrils. Facial neuralgia or headache often follows the subsidence of the asthmatical paroxysm; and this he adduces as another proof of the trigeminal nerve being the origin of the disturbance. Physicians will be grateful for any fresh light that is thrown upon the nature of spasmodic asthma, and especially upon the possession of remedies which will have a more lasting effect than any now in vogue. Perhaps if attention be directed to topical medication—by means of

pencilling or snuff-taking—of the nasal mucous membrane rather than of the whole respiratory tract, a more certain method of relief may be found, at least in those cases where it is impossible to assign any other source of reflex irritation.

Is Alcohol a Food?—Regarding the much-disputed fate of alcohol in the animal system, Professor Cloetta recently published some original investigations. The conclusions he arrives at are: That alcohol becomes converted in the system into carbon dioxide and water; that only a very small proportion passes off as alcohol by the lungs, kidneys, and skin, and that nearly the whole of the quantity consumed becomes oxidized. None is found in the fæces or milk. In moderate doses it has no influence on the body heat, and it only lowers it when taken rapidly and in large quantity, the effects being the same whether fever is present or not. In the tissues, in consequence of absorption of oxygen by the alcohol, tissue metamorphosis is checked, and the essential constituents of the urine are diminished. Alcohol is in so far a food, that it protects against too rapid consumption. It is thus an important agent in febrile cases in daily divided doses of five to seven drachms. In larger doses its importance as a nutrient and conserving agent recedes, and its effects become injurious, and accumulation of the terminal products of tissue metamorphosis takes place, along with increase of uric acid and urea. This fact indicates that oxidation in the tissues has its limits, and that the terminal products of tissue metamorphosis may be produced in other ways.—*Medical Press*, October 21, 1885.

The Treatment of Cephalocele and Spina Bifida.—A paper by Professor Schatz, of Rostock, on the respective advantages of expectant and operative treatment of cephalocele and spina bifida, is of some interest when considered in relation with the report lately presented to the Clinical Society by its Spina Bifida Committee. Taking as his text the expressed opinions of Heinecke and Steffen, both of whom speak in gloomy terms of the prospects of success after any radical operation, he presents a list of cases of encephalocele to illustrate the relative prognosis with and without operative interference. Of 105 cases, 59 were occipital and 46 frontal in position. Of the former, 24 were left untreated, and only 3 recovered, 35 were operated upon by incision, injection of iodine or ligature, with 6 recoveries. Of the frontal encephaloceles, 6 out of 32 survived without treatment, and only 3 out of 14 cases after operation. A few cases of spina bifida, quoted from Lorinser, show much the same proportion of success, and, in the opinion of that author, justify the view that no operative interference should be attempted when it can be clearly shown that a communication exists between the sac and the vertebral canal. Professor Schatz himself considers that operation is only justified when there is no such communication, and when the tumor is covered with healthy skin, is fully translucent and not painful. In other cases, however, he would endeavor to secure the isolation of the tumor from the arachnoid cavity by means of graduated constriction or pressure calculated to set up a process of plastic adhesion, when applied to the base or pedicle, if there be one, of the tumor. He relates the particulars of three cases in which he operated by emptying and removing the sac, the base or pedicle of which was firmly secured by means of a long clamp, such as is at times used to secure the stump of an ovarian tumor. His first case was one of spina bifida, and was not successful in saving the life of the child. In the second a large encephalocele was successively emptied and removed with but little disturbance of the child's health, life being prolonged to the eleventh year. The symptoms and physical signs of internal hydrocephalus were, however, always present, and gradually increased, the child remaining paralyzed in the lower limbs and of very feeble intelligence. In the third case, a series of encephalic protrusions were in like manner clamped and removed, and notwithstanding the great extent of the hernia, the case, after some suppuration and many fluctuations of temperature, ultimately recovered, and is still living, although with a steadily increasing hydrocephalus. All these cases were in themselves severe, and hence the merits of the operation must be considered apart from them: it is possible, however, that the method of compression by clamps, when applied to the more simple cases of the kind, may be found to enhance the chances of success to a very considerable degree.—*Berliner klinische Wochenschrift*, No. 28, 1885.

Ptomaines.—Professor L. Brieger, of Berlin, has recently published a monograph in which he gives the results of his own researches into this interesting subject. From fibrine digestion he obtained a poisonous substance named by him *peptoxi*. It crystallizes with difficulty, and is readily soluble in water. It gives precipitates with most of the common alkaloid reagents. A few drops of a dilute aqueous solution suffice to kill frogs in fifteen minutes. Those experimented on became paralyzed, and were insensible to irritations. Symptoms of paralysis also showed themselves in rabbits after subcutaneous injection of the solution. From human and other decomposing muscle-flesh he succeeded in isolating a new poisonous substance, *eurindine*. It crystallizes in hydrochloric acid combination. From the mother liquor of nuridin a second base, *neurine*, was obtained ($C_5H_{13}NO$) which has a poisonous action on both warm and cold-blooded animals. A few milligrammes act on cats; 0.04 gramme pro kilo kills rabbits with a constant train of symptoms, among which are profuse secretions from the mucous surfaces and powerful clonic convulsions. Atropine was an efficient antidote to the poison. Three bases were obtained from decomposing fish that had been exposed to the air for five days: 1. *Entylediamine* ($C_5H_{12}NO_2$). Frogs showed a certain tolerance of this; rabbits were scarcely affected by it; but in the case of mice and guinea-pigs it produced a copious secretion from the nose, mouth, and eyes, dilatation of the pupils, and dyspnœa. 2. A substance analogous to muscarine. Injected subcutaneously into rabbits, it produced copious secretions and excretions, dilatation of the pupils, and convulsions. Atropine prevented the action of the poison. 3. *Gadinine* ($C_7H_{17}NO_2$), which appeared to be innocuous. From ten pounds of cheese that had been decomposing in water for six weeks, neuridine and trymethylamine were obtained. Neuridine and dimethylamine were also obtained from decomposing glue. The writer remarks in conclusion that the ptomaines form two classes—the poisonous and the non-poisonous—and that we are no longer justified in imputing chemical putrid infection to *none sepsi*. The formation of chemical poisons by the action of formed or unformed ferments is now proved. The character of the soil determines the synthetic power of the bacilli of decomposition. Thus, putrid muscle gives rise to the poisonous neurine, and putrid fish to the poisonous muscarine. These substances give rise to symptoms that have their analogues in certain forms of disease. The writer is now directing his attention to the ptomaines to be obtained from the human body as it undergoes different forms of decomposition.—*Medical Press and Circular*.

Pathogenic Microbes Transmitted to the Fœtus.—Dr. Koubassoff has communicated to the Académie des Sciences a paper on the relations of the fœtus to the mother in infectious diseases (*L'Union Médicale*, July 18, 1885). He injected cultivations of the bacillus of anthrax under the skin of pregnant guinea-pigs. It was found that these bacilli always pass from the mother to the fœtus. He further found that inoculation of pregnant females with a too powerful vaccine nearly always causes the death of the fœtus; that inoculation with a virulent virus after the mother had been protected by satisfactory vaccination nearly always killed the fœtus.

In other words, the fœtus cannot be protected by maternal vaccination. After the publication of the above Dr. Koubassoff continued his experiments on animals, and addressed a second communication to the same scientific body on August 21, 1885. The conclusions of this paper are as follows: (1) The bacilli of anthrax and of tuberculosis inoculated in the case of pregnant females pass into the lacteal secretion. (2) Once noted in the milk, they remain there until the end of lactation or until the death of the female. (3) The offspring nourished with milk containing these bacilli do not take these diseases, and continue to live in cases where the mother dies. (4) The passage of microbes from the mother to the fœtus depends probably on the existence in the placenta of direct communications between the vessels of the mother and those of the fœtus. It is to be hoped that these experiments may be extended to the study of erysipelas and other diseases. Long before the erysipelas coccus was described, or even thought of, observers have put to themselves the question, Is not puerperal erysipelas transmissible to the fœtus? The possibility of such transmission was suggested to Kaltenbach (*Centralblatt für Gynäk.*, No. 14, 1885) by the observation of an infant presenting at birth a well-marked desquamation of the head, neck, and back. The mother had recently had two attacks of erysipelas, the last corresponding exactly in period of evolution to the desquamation observed upon the infant. Careful examination of the patches of desquamation and of the placenta for the micro-organisms of erysipelas gave only negative results, but the length of time which had elapsed since the beginning of the affection might explain their absence. In 1879 Dr. Runge observed the following case (*Centralblatt für Gynäk.*, No. 48, 1884): When the erysipelas coccus was yet unknown, a pregnant woman developed an erysipelas on the left leg, which soon spread to the thigh. Thirteen days after the cessation of febrile movement, while desquamation was still in progress, she was delivered of a child, which presented absolutely similar desquamation of the neck, chest, and abdomen.

Simple Method for the Detection of Biliary Gravel.—Dr. Merle, of Vichy, in a communication to the Académie de Médecine, describes what he terms biliary coniasis, or biliary gravel. Pain in the hepatic region is the most important symptom. In order to detect the presence of biliary gravel, Dr. Merle recommends pouring hot water on the stools. The gravel necessarily falls to the bottom. When poured into a clean receptacle and washed, it is easily recognized.

Iodic Purpura.—At a recent meeting of the Harveian Society (*The British Medical Journal*, October 24, 1885) Mr. A. Q. Silcock related the case of a woman who was admitted into St. Mary's Hospital on account of proptosis. Although no history of syphilis could be obtained, iodide of potassium was prescribed in ten-grain doses three times a day. After the lapse of thirteen days the dose was increased to fifteen grains; seven days later a purpuric eruption appeared, most marked on the legs. Arsenic was then prescribed, in combination with the iodide, the rash disappearing after three days. The arsenic having been discontinued, the spots recurred in an aggravated form. Five minims of liquor arsenicalis were again added, and this was followed, in six or seven days, by a disappearance of the eruption and by general improvement. Arsenic was omitted; the rash again returning after ten days, accompanied with malaise and some catarrh. After this the patient lost courage, and ceased to take her medicine regularly. A few months later the iodide was again prescribed, and once more slight purpuric spots appeared after a few days, when the drug was finally omitted, the case being regarded as one of exostosis or of ossifying chondroma. In his remarks, Mr. Silcock rejected the view that the effect was due to increased diapedesis, such as is said to follow the intravenous injection of salines. Arsenic was prescribed in the hope that it might possess the same specific influence which attaches to its administration in bromide eruptions. He believed that it was frequently prescribed conjointly with iodide of potassium. In the course of the discussion which followed, Mr. Malcolm Morris alluded to the rarity of recorded cases of iodic purpura. The exceptional case published by Dr. Mackenzie deserved mention, the child having died from purpura after a single dose of two and a half grains. Even in the rash of bromide, arsenic after a time lost its beneficial effect. The paper was of great value as demonstrating that purpura was not a disease, but a symptom. Dr. Lees considered the case one of idiosyncrasy; in cases of meningitis he had administered to children large doses of iodide of potassium (three grains every three hours), for weeks and months, without any toxic effects. Children were more liable to the rash of bromide, adults to that of iodide of potassium.

The Use of Ether as an Intoxicant.—One of the members of the Diocesan Synod of Armagh, at its recent meeting, made reference, in discussing the report submitted on temperance, to a practice which exists in various parts of the north of Ireland, namely, the consumption of ether instead of whiskey. A large traffic exists in ether, more especially as it is a cheaper intoxicant than whiskey. Several cases of insanity are stated to have occurred from the excessive use of ether, some at present being in the Omagh and other lunatic asylums.—*British Medical Journal*, October 24, 1885.

The Non-contagiousness of Leprosy.—In an instructive paper on this subject by Dr. Fitch, of Honolulu, the author gives his reasons for believing that leprosy is not communicable from person to person (*Pacific Medical and Surgical Journal*, October, 1885). He sums up the evidence in favor of this view as follows: First, women conceive in numerous cases by lepers, and neither the women nor their offspring develop the disease. Second, as we have seen, drinking the saliva of a leper for years, and smoking the same pipe, fail to reproduce the disease. Third, in ten cases of inoculation, the disease is not communicated to those so inoculated in a single instance. Fourth, men married to leprous women, and *vice versâ*, are no more likely to contract the disease than are those who hold no known intercourse with lepers. Fifth, leprous parentage is no assurance that the child will become a leper. Sixth, segregation plays very little part in the decrease of the disease. Dr. Fitch then continues that, in view of these facts, he believes himself to be fully justified in saying that leprosy is a disease which cannot be communicated from a leper to any other person, by, through, or under any combination of circumstances, except heredity. That even this plays but little part in the propagation of the disease, we may know from the fact that from 1866, when Kalawao leper settlement was founded, until March 31, 1884, 2,941 lepers were consigned there, and up to October 9, 1884, only twenty-six children born in the settlement were alive, where either parent was a leper before the birth of the child. Peter Mikona is the only case that he has been able to find, so far, the parent being a leper previous to the birth of the child, who has lived to mature age and in turn become a parent. Cases where the child is born while the parent is still in the quiescent or even active stage of syphilis, and parent and child both develop leprosy afterward are common enough. Unfortunately, the fact that the disease is non-contagious does not, so far as this country is concerned, do away with the necessity for segregation; for, let a native be ever so loathsome and disgusting an object, that, to his ideas, is no reason why he should not make a public exhibition of himself, and therefore, as a measure of public decency, the community must put the leper away from others by process of law. The author believes leprosy to be a fourth stage of syphilis, or a form of scrofula subsequent to syphilis, occurring but rarely except in a virgin race, or contracted from a member of such race; and then

only in persons of a broken-down, or cachetic, nervous constitution, and rarely met with among Anglo-Saxon or Celtic races, except in blondes. On November 14, 1883, he inoculated six lepers with the virus of syphilis, by taking six ivory vaccine points, and scraping off the surface of a mucous patch on the under side of the lower lip of a native woman. The points were then allowed to dry, and in three hours after he transferred the virus to the arms of six leper girls under twelve years of age. December 14th, following, he repeated the experiment, taking the virus from a hard chancre on the penis of a Portuguese who came to his office. He saw this same man in March, 1884, three months later, in the office of a brother physician, and found he was suffering severely from secondary syphilis. The last time he used fourteen points, and inoculated fourteen lepers therefrom; but no result followed in any of the twenty experiments.

Hæmatemesis and Melæna in the New-born.—At a recent meeting of the Clinical Society of London (*British Medical Journal*, October 17, 1885), Dr. Sawtell read particulars of this case, and exhibited a preparation of the stomach showing ulceration. A small male child, born April 9, 1885, after a natural, but rather tedious, labor, suddenly vomited blood twenty-one and a half hours after birth; and, a few hours later, melæna succeeded. Up to this time milk was taken, and vitality seemed but slightly impaired. The discharge of blood continuing, much altered by admixture with meconium and mucus, the child rapidly sank, and died within twenty-four hours from the first appearance of blood. Besides general measures, sulphuric acid was given in tincture of cardamoms. Post-mortem, the stomach alone showed casual lesions, namely, small, but deep, round or oval ulcers, on the posterior wall of the cardiac end, near the lesser curve. Dr. Sawtell remarked that, after some examination of the subject, he had failed to find any record of a similar case. He quoted Billard's paper, in the *British and Foreign Medico-Chirurgical Review* for 1853, in which Rahn-Escher stated that softening of the stomach and bowel was sometimes found. An interesting case, observed by Dr. R. Neale, revealed no lesion of any kind. Dr. Edis, in the *British Medical Journal* for 1879, dealt with spurious hæmatemesis; so also Dr. Thorburn. But records of true intestinal hemorrhage in infants were so rare that Dr. West related only three as occurring in his extensive practice, and only one of these in the new-born. Finally, Rilliet's elaborate essay did not give any cases of ulceration. The author inclined to the opinion that the ulcers arose from portal obstruction and erosion by gastric juice, and concluded his paper by pointing out the difficulty of diagnosis and treatment, and the truth of Dr. West's observation, that the new-born suffered less from the effects of hemorrhage than might be expected.

The Initial Lesions of Pulmonary Tuberculosis.—The Paris correspondent of the *British Medical Journal*, October 27, 1885, writes that, at a recent meeting of the Paris Biological Society, M. Thaon, of Nice, read a paper on the initial lesions of pulmonary tuberculosis. The author has examined a considerable number of pathological specimens taken from different animals; also the lungs of animals which had died from experimental subacute pulmonary tuberculosis, or chronic tuberculosis, according to the will of the experimenter. Guinea-pigs fed morning and evening on tuberculous sputa, powdered and mixed with sterilized water, invariably died on the twelfth or fourteenth day. The lungs were a solid, compact mass of a reddish brown color, covered with yellow spots. On making a histological examination, the tissues presented small separated areas of lobular pneumonia, measuring about one-third of a millimetre; treated with picrocarmine, they were colored a deep red. They consisted of closely packed cells undergoing proliferation, free from degeneration, and were lodged in the beginnings of branching bronchial tubes. Similar lesions were observed in the pulmonary alveoli; corresponding miliary masses were also grouped round the pulmonary vessels, resulting from the infiltration from the lymphatic vessels. Bacilli were present in considerable numbers in the areas of miliary pneumonia; in those of catarrhal pneumonia they were less abundant. Bacilli could be observed migrating from the bronchi into the alveoli; there they provoked proliferation of the pulmonary epithelium, and its subsequent degeneration. Giant-cells, the zones of epithelial cells, which formerly were recognized as the characteristics of tuberculous granulations, also the various fibrous transformations special to pulmonary phthisis, were only observed in organs far advanced in tuberculosis. The bacillus, M. Thaon says, is the agent which produces all these changes. It is seen in the centre of the cellular elements in the giant-cells, and does not disappear until the caseous masses become one uniform vitreous mass.

Surface Temperature of the Abdomen in Enteritis of Children.—Dr. Moncorvo, of Rio de Janeiro, has published a very interesting account of his studies in this direction (*Journal d'Accouchements*, October 15, 1885.) He divides his little patients into two classes, the febrile and the non-febrile, according as the diarrhœa is attended or not with an elevation of the general temperature. The normal temperature of the abdominal surface in children varies, the author states, between 94.5° and 95.5° F., but it is always considerably higher in febrile diarrhœa, the average elevation being 100°. But it is especially in cases of subacute or chronic apyretic enteritis that he regards the surface thermometer as an invaluable aid to diagnosis. In a general way, he says, he has been able to satisfy himself by numerous observations that the temperature of the abdominal parietes rises a little, even before the diarrhœa begins. And, on the other hand, he often met with cases in which the diarrhœa had seemingly disappeared, but in which the surface temperature remained at 96° F., or above. But in these cases he invariably found, on interrogating the mothers, that the stools, though possessing some consistence, were not yet formed, an indication that the mucous membrane had not yet returned to a healthy condition. In apyretic enteritis the temperature of the surface varies between 96° and 99°, rising and falling with the increase or decrease of intestinal inflammation, affording thus an indication of the progress of the disease and of the benefit obtained by treatment.

Urticaria in Young Children.—At a meeting of the Clinical Society of Paris, Dr. Comby read a paper upon this subject, in which he stated that urticaria in young children was often due to dilatation of the stomach. He reported several cases in children between one and one-half and three years of age, in which there was an evident relation between the repeated attacks of urticaria, from which they suffered, and digestive troubles consequent upon dilatation of the stomach. If the skin affection be treated solely by baths and topical applications, without regard being had to the pathogenetic condition, the result will surely be a failure; but if the stomach affection be overcome by a dry régime the urticaria will disappear. In addition to a dietetic treatment it is well to conjoin washing out of the stomach and the administration of pepsine and other remedies to aid digestion.—*Journal d'Accouchements*, October 15, 1885.

Ergotine in Meningitis.—Dr. Lacroix has published a number of observations of acute meningitis cured by ergotine. He was led to use this remedy from the consideration that in this disease the vessels are first dilated and then follows the exudation. He gives the extract of ergot in a mixture of fifteen to thirty grains for children four years old, and of forty-five grains to a drachm for adults, in four ounces of water. Of this a teaspoonful is given every half hour.—*Rivista Clinica e Terapeutica*, No. 9, 1885.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, November 21, 1885.

THE HISTORY OF THE TROUBLES OF THE NINTH INTERNATIONAL MEDICAL CONGRESS.

AN esteemed correspondent, who has recently returned from Europe, writes us that he met very few, if any, physicians who understood the nature of the International Congress muddle, and that he himself is still rather in the dark. We are requested to state the case again.

At the meeting of the American Medical Association, in the spring of 1884, it was decided to extend an invitation to the International Medical Congress to hold its ninth session in this country. A committee of seven was appointed, and authorized to extend this invitation in the name of the Association and of the American medical profession; also, if the invitation was accepted, to proceed with the work of preliminary organization. The invitation was given and accepted, it being perfectly understood at the time that no local, ethical, or medico-political issue should be introduced. The committee then became a Committee on Arrangements, and it proceeded, as empowered to do by the resolution creating it, to nominate the officers and formulate the rules and regulations of the Congress. Their work was very nearly completed early last spring, and its results were published in pamphlet form. There was an almost, if not completely, unanimous commendation and indorsement of this work by the medical press throughout the whole country, the officers nominated being about as nearly a representative body of men as could be easily selected.

When the American Medical Association met at New Orleans last spring a report of what had been done was made. Instead of being received favorably, this report excited a great deal of indignant criticism, combined with some strongly vituperative condemnation. The charges were, first, that the committee had given its own members too many good positions; second, that it had appointed too many gentlemen from Philadelphia and the East, and had not sufficiently recognized the claims of the West and South; third, that it had appointed as officers, and had allowed the privileges of membership, to gentlemen having so-called "New-Code" affiliations. As the New Orleans meeting was not a large one, and as its membership was made up mostly of gentlemen from the South and West, a resolution to revise the work of the committee and to enlarge its membership by the addition of a representative from each State and Territory, and from the Army, Navy, and Marine Hospital Service, was easily carried. This new committee, therefore, composed of over forty gentlemen, instead of the original seven (later eight), held its first regular meeting after adjournment of the Association in Chicago last June. It then proceeded to organize and lay down its policy. This policy embraced the elimination of all "New-Code" men from the organization and membership of the Congress, and a revision on a basis of geographical representation of the list of officers of the Congress.

This repudiation of the work, authority, and policy of the original committee, together with the election as officers of the committee of gentlemen not widely recognized as leading or representative men, caused most of the members of that committee to resign. Their resignation was quickly followed by the resignation of nearly all the leading officers of the Congress, and of many others, to the number at present of over one hundred and seventy names.

The action of the new committee, like that of the Association at its meeting in New Orleans, met with the most wide-spread and earnest disapproval from the medical press and leading medical men both of this country and England.

The grounds of criticism were and still are as follows:

First, that an organization of the Congress, which had been widely approved and was proceeding smoothly, should have been interrupted.

Second, that this interruption and rejection of the work of the first committee was really incited by a few malcontents, who took advantage of a small and unrepresentative meeting of the Association to effect their ends, and that it was not the real expression of the feeling of the profession.

Third, that the Association and the new committee have introduced a medico-political issue, viz., that of the Code, into an international scientific body, after an explicit understanding had been given that no such thing should be done.

Fourth, that by this means the Congress has been deprived of the work and help of some of America's foremost physicians and surgeons, and that the large State of New York has been almost disfranchised.

Fifth, that the character of some of the gentlemen who have been most active in promoting the present reorganized Congress is not such as to enlist the support and sympathies of the profession.

The action of the Chicago meeting of the enlarged committee was received with such a storm of indignation and was followed by so many resignations that the new managers became alarmed, and a special meeting was called at this city last September. Great affront was caused by the fact that this meeting was held in secret and its action not disclosed until several days after adjournment, and then only in the organ of the Association. At this meeting it was voted to admit as members gentlemen of New Code affiliations, but none of these were appointed officers of the Congress. Some of the vacancies caused by the numerous withdrawals were filled.

Since the September meeting resignations have continued to come in, and there are as yet no signs of reconciliation. Many of the most important offices of the Congress are still unfilled.

A few weeks ago the Executive Committee of the Congress passed a resolution declaring their independence of the American Medical Association, and thus entirely cutting themselves away from the authority of that body.

It was claimed at the time of the action of the American Medical Association last spring in repudiating the first committee's work that this committee was not really amenable to the Association for its authority, but that after the acceptance of the invitation by the International Medical Congress it became a creature of the latter body. The same gentlemen who denied this interpretation of parliamentary law last spring, now justify the action of the present Executive Committee. Thus the charge of inconsistency and insincerity has been added to the others.

As matters stand at present, the management of the next Congress is in the hands of an Executive Committee representing the new and enlarged committee, the best men of the country have withdrawn from all connection with the Congress, and the great majority of the numerous important vacancies in the list of officers remains unfilled. The sentiment as so far expressed abroad is unqualifiedly adverse to the policy of the present management.

As there seems to be distrust of the Congress abroad and absolute hostility to it at home, the question is asked if it would not be wiser to have no Congress at all.

Under the present policy this seems to be very advisable.

THE HOSPITAL PAY PATIENT ABUSE.

As rightly suggested by one of our correspondents in the present issue, there are two sides to the question of the pay patient abuse. One of these represents the lay management, which in the name of charity and religious zeal, gets all the glory it can from the free work of the medical staff; and the other is the desire on the part of attending physicians to give their services freely for experience and reputation. But there are gross abuses connected with both the management and the medical service. It is mainly the fault of the profession that the lay management of our hospitals dare to act as they do in assuming to be masters of the situation. It has come to pass that managers can make any rules that suit their purposes, whether they be pleasing to the medical staff or not. The members of the staff can resign if they choose, but have no other way of righting matters. If the managers decide to force the members of the staff to attend pay patients for nothing, that practically ends the matter.

Submission on one side engenders arrogance on the other. There are plenty of medical men who stand ready to step with joyous meekness into the vacant places. This is what some may call the glory of professional ambition. But not only the hospital appointee is swindled by being compelled to heal gratis the pay patients in his wards, but he in turn cheats the family physician of many of his just fees. This is being done in one way or another every day in some of our metropolitan hospitals. Private rooms are fitted up for such a purpose, and rich patients are charged merely for room rent and extra nurse hire. Some of these hospitals pose as purely charitable institutions, are ostensibly founded for the care of the sick poor, are constantly appealing to the public for pecuniary aid, and make a pharasaical pretence in their annual reports of the noble work they are doing. It is painful to contemplate that such hospitals are abetted in their unfair practices by members of our own profession who apparently dare not object to the rules laid down for them. The managers know this, and act accordingly. They need go but a little farther, and we shall hear of that culmination of abomination, a dollar medical shop, connected with every hospital in the city.

According to a well recognized law of political economy that which does not pay for itself should not succeed. Success vindicates the utility of every good work. The two factors always go together. If a purely charitable institution cannot prosper on its own simple merits it is better that it should fail than be bolstered up by a rotten system of fraudulent representation. Common humanity is not so dead to all the finer instincts as to allow the really needy to suffer. In a general way the demand for charity is met by prompt and proper assistance. If a free hospital cannot succeed, the fault, if any, must rest upon a heartless community, and no one can in a general way be held accountable. If it is a wrong it must right itself in its own way without the aid of missionaries or hospital managers, even if it should cheat the latter out of the opportunity of proclaiming their so-called charity on the house-tops. In too many cases the word charity is used as a trade-mark for selfish motives on the part of ambitious trustees, scheming medical men, and sectarian cranks.

A STRONG ARGUMENT IN FAVOR OF VACCINATION.

Among the many queries which the present extensive revival of vaccination has raised, is the one relating to the effect of vaccination upon one who has already had small-pox or varioloid.

We have been somewhat surprised to find that vaccination "takes" with those who have had small-pox, two or three such cases having came under notice. Upon inquiring of a physician, whose position at the Board of Health has given him a wide opportunity for observation, he assured us without hesitation that after small-pox vaccination will take always, and in the primary form. Moreover, that vaccination is a surer safeguard from small-pox than small-pox itself, for he knew of instances where unvaccinated individuals had had the disease two or three times.

This information is therefore of great importance, for most people who have had small-pox feel that they are sealed with an immunity greater than a life-time of continued vaccination could purchase for them.

DEATH IN THE HURRY.

A death of a portly man is reported, caused by running after a train. He was seventy years old and could not wait. After severe exertion he jumped upon the platform of the rear car, entered the latter just in time to drop dead from heart failure. The fact points its own moral. And yet old men with weak hearts and heavy

bodies do the thing every day on steamboat docks, railway platforms, up elevated stairways, and at almost every street corner. It is the American fashion to be in a hurry, whether the time is short or not. It would appear to be a reflection on a man's energy and determination not to overtake what is a little ahead of him. Nature sometimes retaliates in the way we mention, and the hapless victim gains all his time at once. He is quite sure then not to be left by his funeral train.

JOHN McCULLOUGH.

From the very beginning of the late John McCullough's illness the character of his disease was manifest. He showed unmistakable signs of general paresis. If he could have been promptly and intelligently cared for and treated at once, some stay in the progress of his malady might perhaps have been secured. As it was, there has been no mystery about his case, and nothing new that could be learned by a post-mortem examination. He died, as was predicted, and of a disease which had been perfectly recognized. John McCullough was one of the best illustrations of what often happens when an untrained brain is subjected to continual and severe emotional visions and other excesses. In such cases (to use figurative rather than technical terms) the vascular machinery that regulates the work of the higher brain-centres breaks down, the brain-cortex degenerates, softens, and is destroyed. If twenty men began life as McCullough did, and continued with habits like his, the majority would end as he did. There was no mystery or "bad luck" about it, but only the operation of inevitable law.

A FRUITFUL FIELD FOR OUR MEDICAL SOCIETIES.

There never was a time when physicians have so uniformly complained of hard times and light practice. They have not for this state of things the philanthropic consolation that sickness, accident, and death are any the less, because the city mortality-rate is not unusually low, and the work in hospitals and dispensaries is more extended than ever.

The fact is that the profession is feeling the inevitable results of many years of injudicious fostering of habits of medical pauperism. It is also feeling the results of the continually increasing numbers of young doctors who simply swarm throughout the city and country. Not one in ten of these earns a good living; but all get a few cases, and the sum total of their activity is felt by older men in established practice.

This increase in the number of young men affects practice not only by drawing away cases but by obliging many to put down their prices to almost insignificant sums.

It is quite time that some serious attempts at checking these evils, that every year grow worse, were inaugurated. Our medical societies would do themselves more credit, and the profession more benefit, by looking out a little for the material affairs of the members, as affected by the causes we have indicated. Instead of wasting a thousand dollars in trying to imprison a few quacks, let us have the money spent in ridding the profession of the incubus of medical paupers and impostors, in fighting useless dispensaries, badly-managed hospitals, and even colleges, if need be.

DOCTORS AND PROHIBITION.

An active struggle is going on at Atlanta, Ga., on the subject of the legal prohibition of the sale of alcoholic liquors. A law passed by the legislature forbids the sale of alcoholic liquors of any kind for any purpose—excepting domestic wines, pure alcohol, and wines for sacramental uses. The physicians of Atlanta have embarked in the controversy as to whether this law shall be applied to that city. Dr. Joseph P. Logan, in a temperate letter to the *Atlanta Constitution*, claims that all the good which alcoholic liquors will do in any case can be done by pure alcohol properly diluted. Drs. W. S. Elkin and Henry Wile take strongly contrary grounds. Twenty-three physicians have signed and published a set of resolutions in which they "raise their voices in earnest protest against the great wrong which is attempted upon the sick, the feeble, and the infirm, whose comfort, whose welfare, and ofttimes whose very existence is dependent upon the judicious administration of some of the several forms of alcoholic stimulants commonly employed as remedial agents." They have also resolved "that the experience of medical men for ages has demonstrated unmistakably that pure alcohol is deficient in some of the most important constituents of the various kinds of spirituous liquors used as medicine, and notwithstanding the folly of legislative enactment to that effect, it can never become an efficacious substitute for them."

These Atlanta physicians are certainly as sincere as they are emphatic and eloquent in these announcements of their views. It may even be conceded that it is to their credit that they defend so vigorously the rights of their patients and the implements of their art. It must be confessed, however, that the case is put a little more strongly than medical science justifies.

The verdict of the profession at present is decidedly against the use of alcohol as a beverage, and opinion is growing in favor of a much greater limitation of its use as a medicine. It is quite untrue that "the medical experience of ages has demonstrated that pure alcohol is deficient in some of the most important constituents" which the physician desires to use in combating disease. The fact is that pure alcohol has been very little employed medicinally as a substitute for ordinary liquors, and the question whether all that can be done medicinally by the drug in any shape cannot be done by pure alcohol is, at any rate, still an open one.

Indeed, if pure alcohol were used instead of the vile concoctions that are now so extensively sold, better therapeutical results would probably be obtained.

We would not be understood as denying positively the assertions of the Atlanta doctors as to the insufficiency, medicinally, of pure alcohol. We only urge that the matter is one of those which is not yet fully tested. And perhaps our Southern confreres are right in not wishing to have Atlanta made the field of an extensive experimentation.

The Vacancy in the Chair of Practice of Medicine in the Long Island College Hospital.—The death of Dr. Armor creates a vacancy in the faculty which is to be filled by the best available man. All applications should be made to Dr. A. J. C. Skene, Brooklyn, N. Y.

News of the Week.

The New York State Board of Health held its quarterly meeting in this city during the past week. The report of the Executive Committee showed that the expenses for the year ending September 30, 1885, were $25,719.55. The work of bringing up arrearages in vital statistics has been satisfactorily continued throughout the year, and 51,800 certificates of births, deaths, and marriages have been thereby recorded. The Secretary reported what means had been adopted by the Board to ward off the introduction of small-pox from Canada. The most of its efforts have been in the direction of calling into active existence the local boards of health along the northern frontier of the State, and insisting upon the immediate vaccination and revaccination of all unprotected persons at all exposed points within their jurisdiction. So successful have been the measures adopted that small-pox has been reported in only eight localities of the State outside of the cities of New York, Brooklyn, Yonkers, and Albany, which are by law exempt from the control of the State Board. The chemists of the Board reported their progress in examining food and drugs for adulteration. Their report revealed the existence of extensive departures from the standard in the case of drugs, but affecting commercial interests so large that it was deemed unwise to give publicity to the evidence until more certain results are determined and cases against offenders shall have been prepared.

Medical Department of the University of Wooster, Cleveland, O.—On account of the death of Professor Geo. Hunert, A.M., M.D., the chair of Theory and Practice of Medicine is vacant in the Medical Department of Wooster University, Cleveland, O.

Was it Alcoholismus, or Cocaine-poisoning?—Dr. Lilienthal, of this city, thinks that Dr. J. S. Spear's case of cocaine-poisoning simulating opium-poisoning, "was in reality one of alcohol-poisoning, and that the patient took the large doses of cocaine 'to sober up.' When we read the many cases of alcohol-poisoning recorded in our literature, as in Caspar-Lyman or in Woodman Tidy, we find the same symptoms as recorded here by our navy-surgeons; whereas I cannot find such a state as coma, pinhole-pupil, weak heart, and pulselessness recorded in any work on Coca. Vin Mariani and similar preparations of coca are rather given for toning up a weakened, exhausted nervous system."

Charity Hospital.—As an evidence of the discipline of Charity Hospital, New York City, the Committee on Clinical Records reported for October 422 admissions, and 445 histories of patients, the excess being due chiefly to patients transferred from one ward to another. The average monthly increment of patients is 525, of which number only about twelve per centum of histories has been lost for 1885.

The Late Dr. Samuel G. Armor, of Brooklyn, N. Y.—The following was adopted at the last meeting of the Detroit Academy of Medicine:

Whereas, It has been announced that Professor Samuel G. Armor, M.D., LL.D., an honorary member of this body, and for many years a resident of Detroit, died at his home in Brooklyn, N. Y., on the 27th ultimo, in the prime of his vigor and usefulness,

Resolved, That while we bow in submission to the decree of Infinite Wisdom, yet we hereby express our sense of sore bereavement in his death.

Resolved, That the untiring devotion which our friend has exhibited in his chosen life-work, the large-hearted generosity which he uniformly manifested toward his brother-physicians, and the delicate sense of honor that marked all his dealings with them, together with his thorough integrity and broad manhood, endeared him to the majority of our membership personally in life, and remain enshrined as his best legacy in death.

Resolved, That we extend our warmest sympathy to the great number who, in the death of Dr. Armor, mourn the loss of a friend and teacher.

Resolved, That a copy of these resolutions be sent to the family of Dr. Armor, to the Long Island College Faculty, to the several medical journals of Detroit, and to the New York Medical Record and *New York Medical Journal*.

Edward W. Jenks,
Geo. P. Andrews,
J. F. Noyes,
Committee.

Pasteur's Method of Inoculation against Rabies, and Guerin's Objections.—The full text of Pasteur's description of his method of preventing rabies appears in the "Bulletin of the Académie de Medécine." Pasteur began by saying that, after innumerable experiments, he had discovered a prophylactic method both prompt and practical. It has proved so effective, applied to dogs, as to warrant M. Pasteur in applying it to all animals, even to man. Inoculation of a healthy rabbit, by trephining underneath the dura mater, from a spinal cord removed from a rabid dog, always produced rabies after fifteen days' incubation, on an average. Inoculation of a second rabbit from the first, of a third from the second, and so on through a series of inoculations, provokes a form of rabies presenting in each successive inoculation a shorter term of incubation. After a series of from twenty to twenty-five inoculations, the term of incubation is reduced to eight days. After a further series of from twenty to twenty-five, the term is again reduced to seven, which remains stationary up to the ninetieth. M. Pasteur, in his successive series of inoculations, has arrived at the ninetieth, and there is a very slight tendency in the term of incubation to be less than seven days.

These experiments were commenced in 1882, and they have been continued without interruption. The only virus used was obtained from a successive series of rabbits which died from rabies; consequently, a perfectly pure virus was used in these experiments, and one always identical. This, says M. Pasteur, is the great secret of the method (*le nœud pratique*). The spinal cord of these rabbits is rabid throughout. If a portion of a few centimetres in length be detached from these rabid cords, every cleanly precaution being carefully observed, and then suspended in dry air, their virulence slowly leaves them, and finally thoroughly disappears. The time required to destroy the virulence depends on the thickness of the fragment removed, and still more on the temper-

ature of the surrounding atmosphere. The lower the temperature the longer the virulence persists. If the rabid cord be removed from contact with air into carbonic acid gas, the virulence is maintained during several months, always provided no foreign microbes are allowed to attack it.

In order to render a dog refractory to rabies in a comparatively short time, M. Pasteur proceeds as follows: A portion of fresh rabid cord is suspended in a bottle containing dry air, fragments of potash being placed in it for this purpose. The period of incubation of the rabies is seven days. Every successive day the dog is inoculated by passing under the skin the quantity of sterilized broth a Pravaz's syringe can hold, a small fragment from these desiccated cords having been previously mixed with the broth. The first inoculation is made with desiccated cord that has undergone some days' preparation, in order to be certain that it has entirely lost its virulence. The next inoculation is made with a fresher preparation, and so on until a virulent portion is used. Two days must be allowed to elapse before a fresh inoculation is made. The last inoculation is made from a portion of cord which has been dried one or two days previously. The dog thus treated is rendered exempt from rabies. Inoculation under the skin, or on the cerebral surface, by trephining with the virus of rabies, fails to produce any symptom of this disease. By this method M. Pasteur rendered fifty dogs refractory to rabies without incurring one failure.

M. Pasteur had arrived at this period in his experiments, when two people who had been bitten by a mad dog arrived, on July 6th, at his laboratory, from Alsace. Theodore Vone, a wholesale grocer at Messengott, had been bitten on the arm on July 4th. Joseph Meister, aged nine, was also bitten on July 4th by the same mad dog; the child was bitten in several places on his hands, legs, and thighs; some of the wounds on the thigh were very deep, and caused him to walk with difficuly; the principal wounds were cauterized with carbolic acid at eight o'clock in the evening. The third person was the mother of Joseph Meister, who had not been bitten. M. Vone had his arm very much bruised, but he assured M. Pasteur that the bite had not passed his shirt. He was sent back to Alsace. On July 6th, sixty hours after the bite, Joseph Meister was inoculated. A Pravaz's syringeful of cord removed from a rabbit dead from rabies was injected under the skin on the right side. The rabbit died on June 21st; the marrow had been preserved in dry air from that date, a period of fifteen days. The following days fresh inoculations were made, morning and evening; each succeeding inoculation was made with cord more recently prepared; thirteen inoculations were made, covering a period of ten days.

M. Pasteur does not believe that the progressive attenuation of the rabid spinal cords enclosed in dry air is due to the action of the air. Facts that he will describe later on negatived this interpretation. He considers the cause more probably to be explained by the microbes, the origin of rabies, producing, during their cultivation, a substance endowed with a property hostile to their own development. Data already acquired concerning the *modus vivendi* of these organisms encourage the belief in this hypothesis. M. Pasteur will continue his researches on this subject, and publish the results. Since October 20th, M. Pasteur has had under treatment for rabies a young shepherd, fifteen years of age, who, on the 14th of the same month, had been badly bitten on both hands by a mad dog. The results of this further test of his prophylactic method against rabies will be made known to the Académie des Sciences.

At the close of Pasteur's communication, M. Jules Guerin rose, and after some difficulty obtained leave to put on record the following protests: 1st, That M. Pasteur made his inoculations with the virus of an artificial rabies, there being no proof that his rabbits really had the genuine disease; 2d, the patient on whom M. Pasteur had experimented was not a proper one, since his wounds had been treated with carbolic acid, and since bites of rabid dogs are not always followed by hydrophobia; 3d, M. Pasteur had only found a preventive for rabies, not a remedy for the declared disease.

Careless Comments on Royalty.—It is all very well for the laity, but it is hardly the proper thing for *The Lancet*, to speak about "the Queen's movements."

What Cocaine May not Do.—The knowledge of the therapeutic virtues of cocaine has made such strides during the year, that it would seem a better method of pursuing investigation, and entering upon classification, to do it in a negative way, that is, by making a list of those diseases in which it cannot be used.

The American Public Health Association will hold its Thirteenth Annual Meeting at Washington, December 8 to 11, 1885.

A Successful Medical Society.—On October 28th the Berlin Medical Society celebrated its twenty-fifth anniversary. An opening speech was made by Virchow, who recalled the names of the distinguished members of the Society in the past, and announced that Professor Eulenberg had given the Society 10,000 marks as a fund for securing a suitable building for its meetings. Speeches were then made by Fränkel, Bergmann, and others.

Dr. Thad. M. Stevens, the first secretary of the Indiana State Board of Health, died at his home in Indianapolis, last week, of congestion of the brain. His death was quite sudden. He was fifty-four years of age. He was a nephew and namesake of Thaddeus Stevens, the great commoner. He readily took rank in the profession of medicine, and paid great attention to sanitary science. He was a member of the American Public Health Association, in which he took great interest.

The Small-pox.—The Secretary of the National Board of Health reports that, during the week ending November 4th, there were 233 deaths from small-pox in Montreal and 89 in adjacent municipalities. Dr. J. T. Reeve, Secretary of the State Board of Wisconsin, under date of October 26th, states that, notwithstanding the precautions taken, a second outbreak of small-pox, brought from Montreal, has recently occurred in the State. The first outbreak was promptly suppressed, and, it is expected, by the adoption of similar vigorous measures, to prevent the spread of the disease on the present occasion.

Reports of Societies.

NEW YORK STATE MEDICAL ASSOCIATION.

Second Annual Meeting, held in New York, November 17, 18, and 19, 1885.

TUESDAY, NOVEMBER 17TH—FIRST DAY—MORNING SESSION.

THE morning session was called to order by the PRESIDENT, DR. JOHN P. GRAY. After the announcement by the Secretary of the number of attendants from each district, the annual

ADDRESS BY THE PRESIDENT

was delivered, which dealt principally with the question of the State having power to license doctors, and its effect upon medical schools. Schools of special education, as theological seminaries, law and medical schools, and institutions of technology are sustained by private contributions. Such institutions receive no privileges or grants from the State, and medical colleges do not seek pecuniary assistance from such source. No immediate legislative interference is called for in this matter, either in the interests of medical schools or medical science. The State cannot adopt any particular school or system of medicine as against another, and hence has acknowledged the legal equality of the graduates of all schools. It has been claimed that the State should create an examining body, independent of the schools, and practically take away from corporate schools of medical learning, to which the State contributes nothing pecuniarily, the power of examining their own pupils. This would be an anomaly in political economy. The English and German governments are cited as precedents to encourage State interference. Our Government, however, is not parental. and

MEDICAL COLLEGES ARE THE PROPERTY OF PRIVATE INDIVIDUALS.

Medical students likewise pay for their education. Teachers are striving to elevate the standard of medical education under great difficulties.

The annual reports of the Presidents of Branch Associations, and of the New York County Medical Association, giving the work of the year, was next presented.

THE ADDRESS ON STATE MEDICINE

was delivered by DR. ALFRED L. CARROLL, of Richmond County.

State medicine includes medical jurisprudence, medical education, and public hygiene. In the public mind, the latter assumes the greatest importance. State medicine constitutes the oldest specialty in medicine. Moses was eminent in this branch, and some of his rules might be well copied at the present time. Circumcision was taught with reference to its hygienic effects. The causes of disease should be carefully sought out. Hippocrates was eminent in this field. Galen wrote much on hygiene. The earlier teachings dwelt most upon personal hygiene. The sanitarian must be primarily

AN ACCOMPLISHED PHYSICIAN,

not a mere engineer or architect. All sanitary studies must be based on medical knowledge and experience. Medical schools almost entirely neglect the important study of hygiene, and appear to overlook the necessity of a preliminary knowledge of the science. There are thirteen hundred local boards of health in this State, and in examining for health officers, the utmost ignorance is often displayed. Only about ten per cent. of our graduates have any conception of the period of incubation of contagious diseases or the cubic feet of air necessary for each individual in a room.

A SCATHING REBUKE TO THE COLLEGES

was next administered for their laxity in admitting and graduating students.

THE PRELIMINARY KNOWLEDGE OF MANY MEDICAL STUDENTS IS ON A LEVEL WITH THAT OF A RETAIL GROCER'S CLERK.

Our metropolitan colleges are no better than country institutions in the matter of preliminary requirements. In England, hygiene is included in the four years' course. Sanitary legislation suffers at the hands of wholly ignorant demagogues and half-educated persons. From twenty to thirty per cent. of the death-rate can be reduced by sanitary measures. This pays in a financial point of view. The causes of disease must be studied more by physicians before sanitary science can be much advanced.

AFTERNOON SESSION.

The first paper was read by DR. HENRY DIDAMA, of Onondaga County, entitled

TUBERCULAR CONSUMPTION—IS IT EVER INHERITED?

The speaker said that he started with the assumption that tuberculosis was an infectious disease, due to the presence of a specific bacillus. After reviewing the literature of the subject, he read a letter from Dr. Wise, describing an epidemic of tuberculosis among cattle, in which the disease was found many times in very young calves, and even in fœtuses. He thought there could be no doubt that the disease could be transmitted in cattle, but the conditions in the human subject were different, and, notwithstanding much search and the examination of many dead infants, no case of inherited phthisis had yet been found. The author concluded that (1) tubercular consumption is not hereditary; (2) there is no peculiar inherited tendency, although (3) children of tuberculous parents, as well as those of other parents debilitated by disease, may be weak and in this way predisposed to acquire tuberculosis. And that they are more likely to become phthisical is to be explained by the fact that they are living in an atmosphere of the disease, and thus more exposed than are the children of other debilitated non-tuberculous individuals. The therapeutical indications, the author said, were to give the child of a tuberculous mother to a healthy nurse and isolate it from its parent; and, if there were any syphilitic taint, specific treatment should be commenced at once and continued for a long time, in order if possible to fortify the constitution and thus avert bacillary infection.

DR. ROCHESTER, of Erie County, related a case in which he found tubercles and a cavity in the lungs of a child three weeks old. The mother was a strong, healthy woman, but the father had died of tuberculosis before the birth of the child. The speaker believed that this was an evidence of the possibility of inherited tuberculosis.

DR. SIMEON T. CLARK, of Niagara County, then read a paper on

PSOITIS AND PERIPSOITIS,

reviewing briefly their pathology and differential diagnosis, and relating the histories of three cases of psoitis which had recently come under his observation.

DR. HYDE, of Cortland County, said that these acute abscesses were at first unconnected with the vertebral column, but that when left alone they eventually set up caries of the spine, and then at the autopsy the case is diagnosed as one of Pott's disease. His conclusion was that an early evacuation of the pus was absolutely necessary, and we should never wait for the abscess to point.

DR. MOORE, of Monroe County, believed that there was more danger of tubercular infection after opening of the abscess than before.

DR. CHARLES W. BROWN, of Chemung County, followed with a paper entitled

SHOCK, AND THE EFFECTS OF INJURIES ON THE NERVOUS SYSTEM,

in which he detailed the different forms in which shock is manifested, and mentioned the various states which

modified the intensity of this condition. He said that the surrounding circumstances exerted a greater influence upon the progress of the case than is usually supposed, and related an instance in which the patient was apparently doing well, but began to sink immediately after being told by his mother that he would not recover. Treatment should be twofold: 1, To promote reaction by application of external heat and the administration of hot brandy and coffee internally, or brandy hypodermatically; and 2, to control as far as possible the ensuing inflammation.

Dr. Frank H. Hamilton, of New York County, presented a brief paper on

RAILROAD SHOCK.

The author said that there were two forms of this affection. In the first there were early symptoms of shock, but in the other there were no early symptoms. This form, he maintained, was not true shock; there was primarily no injury to the spinal cord, but the condition was one of injury to the ligaments. This injury leads eventually to inflammation, which extends in time to the meninges and spinal marrow. It is then that the remote symptoms are observed. The injury was caused, he thought, by the throwing forward of the upper part of the body, and its sudden recoil, similar to the snapping of a whip-lash.

Dr. Edmund S. F. Arnold, of New York County, read another paper upon the

ESSENTIAL NATURE OF SHOCK,

in which he stated his belief that the phenomena of shock were due to an injury of the nervous centres presiding over nutrition, and to a partial arrest of the latter.

The discussion was participated in by Drs. Kneeland, Hyde, Moore, Kearney, Hendricks, Van de Warker, and others.

Dr. Carlos F. MacDonald, of Cayuga County, reported a case of

INSANITY FOLLOWING GUN-SHOT INJURY OF THE HEAD.

The patient presented a slight depression in the skull in the frontal region, which was the result of a gun-shot injury. It was proposed to trephine the skull, but, upon cutting through the scalp, the bone was found to be open, and through this opening a hypodermic needle was inserted, with the result of finding a cyst. Its contents were evacuated through the needle; and upon recovering from the ether the patient was found to be perfectly rational, while previously he had for weeks been wildly maniacal.

A paper by Dr. O. G. Selden, of Greene County, entitled "A Case of Intracranial Tumor, with Remarks relating to the Diagnosis of Intracranial Disease," and another, by Dr. Simeon T. Clark, of Niagara County, on "Two Peculiar Conditions of the Mammary Gland," were read by title.

Evening Session.

A DISCUSSION ON PNEUMONIA

was opened by Dr. Austin Flint, in which he propounded eight questions relative to the nature, pathology, prognosis, and treatment of acute lobar pneumonia. To the query "Is blood-letting ever indicated?" Dr. Flint answered that thirty years ago he was in sympathy with those who objected to the indiscriminate employment of this agent; now he is in sympathy with those who think it may sometimes be employed. In rare cases it may shorten or abort pneumonia by preventing the overloading of the right side of the heart. It may lessen the chances of a second or third lobe becoming involved. It must be employed early, when there is pain and dyspnœa with fulness of the systemic veins. It is of course contra-indicated in such conditions as typhoid fever, rubeola, and anæmia. Is alcohol useful in pneumonia? Whenever there are symptoms of heart-failure it should be employed. No rule can be laid down for all cases, and a careful tentative use is often indicated. An enormous tolerance of alcohol is sometimes acquired. In sickness there are never any phenomena of intoxication. In regard to antipyretic measures, quinine in large doses is often useful and often very uncertain. The doctor has not arrived at definite conclusions about antipyrine. In employing cold externally, whenever the temperature rises above 103° Fahr., a sheet wet with water at a temperature of 80° Fahr. is wrapped around the patient, who is then sprinkled every fifteen or twenty minutes with cool water. The wet sheet should be kept on until the temperature sinks to below 103° Fahr. If the patient complains of being chilly, he may be wrapped in a dry blanket. Three cases were reported in which the wet sheet acted admirably in reducing temperature. The cold bath may be dispensed with, on account of the fatigue and annoyance that it causes the patient.

Dr. Flint stated that relapses did not occur during or shortly after convalescence from pneumonia, in which respect it acts like an essential fever. Pneumonia likewise leaves no tendency to phthisis.

Question 1. Is acute lobar pneumonia a primary local inflammatory disease, or is it an essential fever, the pulmonary affection being secondary thereto and constituting its anatomical characteristic?

Dr. Didama, of Onondaga County, stated that three views have obtained in reference to pneumonia: First, preceding the attack there is an excess of fibrin in the blood, or hyperinosis. This causes an involvement of the nervous system. The lungs have an affinity for this blood and hence are affected. This view assumes what has not been proven. Second, pneumonia is an ordinary inflammation, induced by a chilling of the surface and other like exciting causes. Soldiers, sailors, and others much exposed, however, are not liable to contract the disease, which is not so prevalent in colder climates. It differs from an ordinary inflammation by the marked chill and sudden defervescence. Third, pneumonia is an essential fever with a local lesion. It is infectious and even occasionally contagious. Why are the lungs or one lobe alone affected? No more reason can be assigned that in the case of the specific lesion of typhoid fever and like diseases. This question is not finally settled, but pneumonia is probably an essential fever with a secondary pulmonary affection.

Dr. Ross, of Chemung County, stated that nothing must be accepted not borne out by fact and experience. A careful study of the pathology of pneumonia is important. Most physicians consider it a local disease, but from the following facts the doctor considers it otherwise: The onset is distinct and well marked; the disease selects by preference certain ages; when the temperature falls recovery quickly begins, although the lung is still seriously crippled; a true croupous pneumonia cannot be artificially induced; there is generally a selection of the right lower lobe, and the prostration is entirely out of proportion to the amount of lung involved.

Question 2. What facts and rational grounds, with our present knowledge, can be cited in support of the doctrine that acute lobar pneumonia depends on the presence of a specific micro-organism?

In answering this question, Dr. Janeway, of New York County, gave a history of the various researches in which pneumococci have been found in the sputa and different parts of a pneumonic lung. Mice, guinea-pigs, and rabbits inoculated with the pneumococci have contracted pneumonia. A strong case can be made out for the pneumococcus as a cause of pneumonia. The microbe acts by gaining entrance to the mouth and respiratory tract, where it grows, thus establishing the disease. In cases of inoculation there may be a mixture of septicæmia with other symptoms.

Question 3. What conditions or circumstances incident

to acute lobar pneumonia tend to render the disease fatal?

Dr. Robb, of Montgomery County, stated that pneumonia is more fatal among blacks than whites, also among females than males. A pregnant woman is in greater danger than a non-pregnant one. Pneumonia is very fatal when the upper lobe of the lung is affected. In cases of debility from alcohol the prognosis is particularly bad. Some years the disease is very fatal, from some epidemic influence. If the temperature reaches 105° F. the attack is very serious. Prune-juice expectoration and an irregular pulse and temperature, or active delirium, are bad signs. A low, muttering delirium and subsultus are always fatal.

Dr. Biggs, of New York County, stated that in six hundred uncomplicated cases the mortality was six per cent. The prognosis is bad in the following instances: 1. Patients with bad habits or in a bad condition; alcoholics especially fare badly. Over five years of age the disease is much more fatal than under that age; in old age the disease is nearly always fatal. The excitement and exertion of moving patients to a hospital may cause a fatal ending. 2. As a complication of other affections, as the exanthemata, chronic Bright's disease, valvular disease of the heart, and after surgical operations, the prognosis is bad. 3. Certain complications of the disease, as purulent infection, abscesses, albuminous urine, pleurisy with effusion, endocarditis and pericarditis render the prognosis bad. Only one per cent. of cases terminate in abscess. 4. If more than one lobe is affected the prognosis is bad; if more than two are involved the disease is nearly always fatal. 5. The intensity of action of the morbific principle affects the prognosis. Malignant epidemics seem to point to a germ theory for the disease. The immediate cause of death is heart-failure, with a collateral œdema of the lungs secondary.

Question 4. Are there known remedies or therapeutic measures capable of arresting this disease, or of exerting a curative influence by either shortening its duration or conducing in any way to a favorable termination?

Dr. Rochester, of Erie County, stated that in the earlier years of his practice a free use of the lancet and calomel gave him as good results as he has since obtained. He has used the carbonate of ammonia for many years, from the very beginning of the disease. He gives from gr. v. to x. q. 2 h. in milk, and a little Dover's powder, if necessary, to quiet the nervous system. Alcohol is to be used only in asthenic cases. The doctor does not believe in arterial sedatives like veratrum viride. For an external application, a large poultice or oil-silk jacket.

Question 5. Is blood-letting ever indicated in this disease, and, if so, what are the circumstances indicating and contra-indicating this means of treatment?

Dr. Clark, of Niagara County, has found a plurality of causes for pneumonia and a varied treatment. In plethoric cases, or where there is exhaustion of the heart with a passive congestion and dilatation of the right ventricle, blood-letting will relieve when stimulants fail. The infrequent and careful use of the lancet will often do much good.

Question 6. Is alcohol useful in the treatment of cases of acute lobar pneumonia, and, if so, what are the indications for its use, and how is its use to be regulated as regards the quantity given, etc.?

Dr. John Shrady, of New York County, stated that as a medicine alcohol has been overrated. In most cases where it is employed, from four to eight ounces a day will prove sufficient. In pneumonia of old people stimulants should be freely given. Alcohol has very little effect upon the temperature.

Dr. Ferguson, of Rensselaer County, stated that the impression through the profession of the good effects of alcohol was vague and not based on statistics. Is alcohol a food? There is no doubt that it is destroyed in the body and gives force, and is therefore food. Especially in disease it acts as a food. Alcohol is a sedative in pneumonia. It temporarily increases the strength of the heart muscle.

The meeting then adjourned.

Wednesday, November 18th—Second Day—Morning Session.

After the transaction of some general business the

DISCUSSION ON PNEUMONIA

was continued.

Question 7. To what extent is it safe and useful to employ antipyretic measures of treatment in cases of acute lobar pneumonia, inclusive of the cold bath, sponging the body, or the wet sheet?

Dr. Charles G. Stockton, of Erie County, believed that antipyretic treatment was very useful when it was not dangerous; but when, as often happens, antipyresis is ill borne, it should not be persevered in. He quoted the views of a number of American practitioners for and against the employment of external antipyretic measures. The speaker himself believed that the selection of an antipyretic should be made according to the indications of the case. He deprecated the use of external antipyretics, with the possible exception of cold sponging. He thought that antipyrine should never be given in doses larger than twenty grains, nor at intervals of less than eight or ten hours.

Question 8. Do relapses of acute lobar pneumonia ever occur during or shortly after convalescence, and does this disease involve any special liability to other diseases or sequelæ?

Dr. John G. Orton, of Broome County, said that during an extensive practice of many years past, he had never met with such relapse, and he did not believe that it could occur, admitting that pneumonia was an essential fever; and he regarded the so-called relapses of other observers as merely due to complications or the involvement of a new portion of the lung. He regarded bronchitis, pleurisy, acute nephritis, pericarditis, and heart-clot as favored in their origin by pneumonia. Meningitis he did not regard as often due to the pulmonary affection. He believed that one attack of pneumonia left behind it a predisposition to subsequent attacks, and he believed that the lung might also be so modified as to offer a nidus for the lodgement of the tubercle bacillus.

Dr. Ely Van De Warker, of Onondaga County, then read a paper on the

MEDICO-LEGAL BEARING OF PELVIC INJURIES IN WOMEN.

The speaker said that the defence, in actions concerning pelvic injuries of women, was always at a disadvantage, since it could not ascertain the real nature of the case, owing to the repugnance of the court to order an examination of the plaintiff. He related several instances of this sort. He believed that many of these plaintiffs were sincere but mistaken, their pelvic troubles dating back prior to the receipt of the alleged injury; but there was another and large class comprising women who were unmitigated frauds. The only remedy suggested was that courts insist upon evidence other than that of the plaintiff or of her physician.

Dr. A. Flint, Jr., of New York County, then delivered the address on

SOME OF THE RELATIONS OF PHYSIOLOGY TO THE PRACTICE OF MEDICINE.

Physiology, the speaker said, is the only rational basis of the practice of medicine. Although empiricism is sometimes useful, its results must be substantiated and explained by physiological knowledge. He illustrated the value of physiological researches in the diagnosis of heart disease, and showed the aid which these studies had given to the advance of physical diagnosis as a science, and to a proper appreciation of the pathology

of cardiac and other affections. The speaker then referred briefly to the medical errors, handed down from former times, which had been overthrown and cleared away by the labors of physiologists. He said that physiology teaches us that fevers should be fed in order to save the tissues, which would otherwise be sacrificed to sustain the abnormal elevation of temperature, and alcohol may be given for the same purpose. Finally, the speaker instanced the discovery of vaccination as a triumph of physiology, and referred to the study of micro-organisms, which latter he believed would eventually lead to the detection of the means both of prevention and of cure of infectious diseases.

AFTERNOON SESSION.

DR. ISAAC E. TAYLOR, of New York County, read a paper entitled

RECTO-LABIAL OR VULVAR FISTULÆ—THEIR CAUSES AND TREATMENT.

Recto-anal fistulæ are of frequent occurrence, recto-vaginal come next in frequency, while recto-labial, or vulvar, are infrequently seen. The latter subject has not received sufficient attention from the profession. The subject is akin to recto-anal fistulæ. Works on gynecology are silent in reference to the glands of Bartholin, their diseases, and the unfortunate results of them. Labial or vulvar abscesses are most usually considered as of trivial occurrence. Under the influence of various causes inflammation ensues, which may be confined simply to the excretory duct, or the gland itself. Eventually the cellular tissue which surrounds the gland becomes irritated and suppuration follows. A fistula may result from this. Vulvar-rectal fistulæ arise from abscesses in (1) the gland itself; (2) in the areolar tissue surrounding the gland; (3) the prerectal vulva. The pathognomonic symptoms are air and very thin liquid fecal matter being discharged.

DR. EDWARD M. MOORE, of Monroe County, read a paper on

RECURRING LUXATIONS,

in which he maintained that this accident was in no sense the fault of the surgeon. Torn or weakened ligaments are common factors in producing a recurrence of luxation.

DR. FREDERICK HYDE, of Cortland County, then read a paper entitled

THE DIFFERENCE IN THE SYMPTOMS OF STRANGULATED OBLIQUE INGUINAL HERNIA.

He thought that much time was often lost in seeking advice in consultation, and that it was better for each one to acquaint himself thoroughly with the symptoms so as to be able to dispense with the advice of others. The speaker formulated a number of conclusions, giving the symptoms of strangulation and the indications for herniotomy.

DR. JOHN W. S. GOULEY, of New York County, deprecated attempts at prolonged taxis, the use of ice and other topical applications, and believed that an early herniotomy was advisable. Even if there were no hernia, this operation was, as a rule, safe.

The paper was further discussed by Drs. Barrett, of New Jersey; Dudley, of New York County; and Ferguson, of Rensselaer County.

DR. JOHN S. JAMISON, of Steuben County, followed with a paper on the

MEDICINAL AND DIETETIC THERAPEUTICS OF THE COMMON FORMS OF CHRONIC INTESTINAL CATARRH.

He said that the catarrh was often kept up by retained fecal masses, and therefore laxative remedies were indicated. Starch should be avoided, as should also sweet preserves.

DR. GARRISH, of New York County, thought hygienic and dietetic treatment was more important than medicinal. Warm clothing and the use of milk were the most important prophylactic measures in children. In dysentery he gave rectal injections of subnitrate of bismuth. Oatmeal he considered harmful.

The paper was further discussed by Drs. Pomeroy, Gillis, Collins, and others.

EVENING SESSION.

DR. ISAAC PURDY, of Sullivan County, read a paper entitled

A CURSORY REVIEW OF THE EPIDEMIC AND ENDEMIC DISEASES OF SULLIVAN COUNTY DURING THE LAST THIRTY-FOUR YEARS.

The paper was an interesting sketch of the medical history of the county, in which the author described the origin and spread of the different epidemics and noted the varying characteristics of each, adverting briefly to the methods of treatment found best adapted to these different types.

The discussion which followed turned principally upon the treatment of diphtheria, and was participated in by Drs. Peters, Cronin, Pomeroy, Gerrish, and others.

DR. W. B. SABIN, of Albany County, related a case of

REMOVAL OF ENTEROLITH,

weighing between four and one-half to five ounces. The stone was removed, after crushing, through the dilated anus. It consisted of petrified fecal matter.

DR. HENRY VAN ZANDT, of Schenectady County, followed with a paper entitled

COMMERCIAL PRESCRIPTIONS,

in which he dealt very severely with the special preparations of the manufacturing chemists, not omitting a few strictures upon the physicians who lend their names to the certificates appended thereto. In the discussion, various remedies for this evil were proposed, but it was agreed that the only efficacious remedy lay in the physicians' hands—they should not use these preparations nor certify to their assumed value.

The next paper read was by DR. ISAAC DE ZOUCHE, of Fulton County, upon

PROPHYLAXIS.

The author dwelt upon the ignorance of the elementary rules of hygiene, so often displayed in rural districts, as well as in cities, and insisted that the physician's sphere lay not only in administration of drugs to cure disease, but also, perhaps even more, in the inculcation of the lessons of cleanliness.

DR. BAKER, of Oneida County, thought it was not so much the *fact* of prophylaxis that needed discussion as it was the *how*. He said that the profession seemed to be apathetic in the matter, much was said but little was done. The discussion then turned upon the Plymouth epidemic, and DR. THORNTON, of Erie County, described the origin of the disease as he studied it when a delegate from the Buffalo Board of Health.

The following papers were read by title: "The Relation of Drink to Insanity," by Dr. G. Alder Blumer, of Oneida County; "Tumors of the Jaw," by Dr. W. S. Tremaine, of Erie County; "The Treatment of Incontinence of Urine in Women, resulting from Hyperdilatation and Paralyzation of the Urethra," by Dr. Nathan Bozeman, of New York County; "Skin-flaps in Amputation and Umbilical Hemorrhage in Infants," by Dr. U. C. Lynde, of Erie County.

(To be continued.)

NEW YORK ACADEMY OF MEDICINE.

SECTION IN SURGERY.

Stated Meeting, Monday, November 9, 1885.

STEPHEN SMITH, M.D., CHAIRMAN.

IS WIRING THE FRAGMENTS ATTENDED BY SUCH SUCCESS AS TO MAKE THIS METHOD THE RULE IN THE TREATMENT OF SIMPLE FRACTURE OF THE PATELLA?

DR. JOHN A. WYETH opened the discussion on the above subject, and formulated his views in answers to the following questions:

1. Can simple fracture of the patella be treated by a method which will secure a perfectly useful limb without danger to the patient's life or limb?

2. If so, what is that method?

Dr. Wyeth said that, in the history of surgery, the first question had been answered affirmatively thousands of times. By the use of the posterior splint, obtaining ligamentous union, he had never treated a case which did not result in a useful limb; perhaps not so useful as that with the original patella, but one which permitted the patient to subsequently perform his usual work without very marked inconvenience.

Thus the second question was partially answered, but the method which he now employed and advised was Hamilton's; that is, the use of a posterior splint of some kind. This method positively incurred no risk to life or limb or comfort of the patient. The posterior splint should never be removed for at least six weeks. The dressing for the anterior aspect of the limb designed to hold the fragments in close apposition—such as the figure-of-8 application of the roller-bandage—should be inspected frequently, perhaps daily, to determine whether or not the desired approximation of the fragments was being maintained.

At the end of six weeks slight passive motion should be begun. The posterior splint should be worn for six months. Some form of splint which furnished a flexion-check must be worn for at least one year longer, making a total of eighteen months during which the posterior splint was worn. The length of time for which the patient is incapacitated for ordinary work was, by this method, six weeks.

3. Is a ligamentous union of one inch or less in length, properly obtained and protected for eighteen months, as strong as bone?

Hamilton says that it is, and Dr. Wyeth had several cases which showed that such a union was even stronger than bone. In 1877 he treated a patient for fracture of the patella, beginning two or three months after the accident occurred, and in the meantime the patient had fallen and succeeded in separating the fragments over two inches. He approximated the fragments, by the method of the posterior splint and the figure-of-8 roller over the patella, to within three-fourths of an inch, and kept the limb dressed for one year only. The result was satisfactory to the patient, and he pursued his ordinary labor without special trouble for five years, when he fell again, and produced a transverse fracture of the upper fragment, the old ligamentous union holding firmly. Dr. Hamilton relates several such cases, and they are not of infrequent occurrence.

4. Does a ligamentous union, two or three inches in length, necessarily imply a loss of function? After an unhappy experience in wiring the patella in 1882, a patient came under Dr. Wyeth's care with this fracture, and practically the case received no treatment. He was placed in bed and an ice-bag applied, and after a time a simple roller-bandage was adjusted which satisfied the patient. In that case union took place with a ligament at least *two inches* in length. The man is still under observation, and can go up-stairs—three steps at once, if necessary—and walk without limping; he can also kneel and raise himself with the limb, and is satisfied with the result of the treatment. Dr. Wyeth was well aware that ligamentous union was very apt to be followed by impaired or imperfect function, and sometimes loss of the function of extension altogether.

5. Does wiring the patella secure a better limb than can be secured by other methods of treatment? Of course, if wiring is successful, and union by bone is complete, thick, and solid throughout, it is better than anything else.

6. Is wiring a safe operation? This was the part of the subject which was most interesting to him, and in connection with it, Dr. Wyeth gave an abstract of a case he had reported in THE MEDICAL RECORD, vol. xxi., p. 596 (1882). A German girl, twenty years of age, during a storm at sea was thrown against the guard-rail, and her left patella was fractured while the leg was strongly flexed. He had at that time never heard or read of an unsuccessful result in a patella which had been wired under antiseptic precautions, and therefore performed the operation under the fullest antiseptic precautions; no untoward event occurred during its performance. The case, however, did badly, and he was obliged to amputate at the middle of the thigh to save the patient's life. At the time of the publication of his paper, he had collected nineteen cases; in five the operation was performed without antiseptic treatment, *three* dying and *two* recovering; fourteen with Listerism more or less modified. Only one out of the fourteen died. One lost the leg. In five cases bony union was supposed to have been obtained. The remaining seven recovered; one with "no bony union," and in the others motion was more or less limited.

After the study of these cases, and in the light of his own sad experience, and from a study of the subject since, Dr. Wyeth was as much convinced of the danger of the operation as he was of his own existence; and also that the benefit derived from a close coaptation of the fragments was not great enough to warrant the risk incurred by opening the joint and wiring the fragments together.

7. If it were a safe operation, would it be preferable to the method of treatment by the use of the posterior splint? Certainly, as between the two he would not hesitate to decide in favor of the latter method.

Some of the prominent objections to wiring were that the operation necessitated longer confinement in bed than the other method of treatment, as the patient must remain there six weeks or two months, with the leg in complete fixation. By Hamilton's method the patient is not confined to the bed for more than three or four days. With wiring the patella the patient is incapacitated for any kind of work for at least six months after the operation. Furthermore, he had recently seen a case in which synovitis was caused by the wires.

8. Are there any cases in which wiring is permissible? Dr. Wyeth thought that the operation should be confined to fractures in which there was a wound communicating with the joint, and in which there must be drainage.

As to other radical methods, such as treatment by means of Malgaigne's hooks, Kocher's method of throwing a wire-loop around above the fragment, one-half the loop going through the joint, and Volkman's method, in which the loop did not pass through the joint, all were objectionable, as he did not see any justification for a method which interfered with the integrity of the skin.

DR. R. F. WEIR continued the discussion, and said that he had not had any experience in the performance of this operation. His surgical inclinations had rather leaned against it. When it was first proposed, it seemed to him that the gist of the question was with reference to the safety of the operation, and Lister claimed that he had sufficient practice in antiseptic surgery to enable him to place complete reliance on its safety. Dr. Weir believed that he had carried out the details of antiseptic surgery as thoroughly as was possible, and that he had

had a fairly large experience in that field; and yet he could not feel that he had confidence in its absolute safety. He thought that all surgeons had had unfortunate experiences and disastrous results, notwithstanding the observance of all recognized and known antiseptic precautions. He had not, therefore, felt that wiring the fragments in simple fracture of the patella was a perfectly safe operation. Dr. Bull's case, quoted by Dr. Wyeth, was certainly a startling one, resulting in death after simple fracture of the patella. He had seen, in the New York Surgical Society, cases in which the operation had been performed, as well as published cases in which it had been claimed that good results had been secured; yet motion did not extend through an arc of more than twenty-five or thirty degrees, an unusual limitation after simple fracture treated by other methods. He had felt that, when treated with a well-secured posterior splint worn for a long period of time, at least three or four months, the case terminating in a separation of the fragments varying from one-fourth to one inch, a very good limb and result had been obtained.

The only argument which he could see in favor of wiring was the fact that occasionally, with a narrow bond of ligamentous union, when the limb is put to some extra motion, the other patella was fractured.

Dr. Weir would feel that, in addition to compound fracture of the patella, where we were warranted in wiring the fragments, there was one condition which possibly might call for interference, namely, those cases in which union took place with half an inch or an inch of ligament, and the bond of union stretched and became three or four inches long. Although patients got along very well with such a great length of ligamentous union, occasional cases occurred in which there was an undue liability to do themselves injury, and therefore an attempt to bring the fragments into closer apposition might be justifiable. He believed, however, that the general sentiment of the profession was concentrating more and more strongly against this operation. He had contented himself with the application of the plaster-of-Paris bandage in the treatment of fracture of the patella, and had obtained as good results with that method as with any which he had employed. He also wished that Dr. Wyeth had added to his test the question, Has aspiration for the removal of serum and blood facilitated recovery?

Dr. Post had had no experience in wiring the patella, and had been very well satisfied with results obtained by the ordinary methods of treatment. He did not consider a limb as perfect with ligamentous union an inch or more in length as it would be with bony union, but it answered well in the performance of all ordinary functions. His opinion had been that wiring the fragments should be reserved for compound fracture and for old fractures with such laxity of the ligamentous union as seriously impaired the usefulness of the limb.

Dr. M. J. Roberts had not had any experience in wiring. He reported three cases treated with the posterior splint, and all the patients recovered with useful limbs, although impaired as to functional activity.

Dr. James R. Taylor had not wired the patella, but had secured average good results by means of the posterior splint, and a device of his own for approximating the fragments.

The Chairman said that wiring the patella for fracture was a frequent operation in Bellevue Hospital. He was induced to perform it with a great deal of reluctance, but had done the operation seven times, and, so far as dangers were concerned, they had all been entirely satisfactory, no unfavorable symptoms of any kind occurring during the treatment. Three were cases of simple fracture, three were cases of old fracture with long useless ligamentous union, and the other was a case of compound fracture.

As far as he observed the three cases of simple fracture, the movements of the limb were not as free as he had seen after the same period of treatment by the posterior splint. He supposed that they would eventually have as free motion as the others. In one old case the amount of flexion was less than fifteen degrees, and the result of the operation was satisfactory.

In one case, a comparatively recent one, he found a condition which was peculiar, namely, both fragments were covered with a shell of bone, apparently a new formation from the upper surface, which broke down very much like an egg-shell. Both fragments were quite soft, except the lower surfaces, which were firm. He sawed off two thin pieces from the fractured borders, and introduced the wire, but it immediately cut through the soft bone, and to make it hold he passed the wire through the entire fragments, and was able to bring the edges together on the internal; but the middle and external portions were not quite in contact. This case did perfectly well, and subsequently the surface of the patella was so covered that there was no evidence of any separation whatever; although the wires were in the joint, the appearance was that of union by bone, and the patient could walk very well.

With regard to St. Vincent's Hospital, wiring the patella had been done there, and, so far as Dr. Smith was aware, with entirely satisfactory results.

The method of treatment which had always commended itself to him was that described by Dr. Weir, and it had given as near bony union as any except wiring. His own impression as to the danger of wiring was, that the operation was not attended by any danger at all. He had not seen any unfortunate results in his own practice, nor in Bellevue, where the operation had been performed eighteen or nineteen times, besides four or five cases in St. Vincent's.

As to how useful the limb became he did not know the general results, but in two of his cases motion was very free, but in a third case it was less free, yet was improving, and the patient was perfectly satisfied with the result of the operation. In Bellevue, passive motion had been begun as early as two weeks after the wiring; of course, practised very gently at first.

Dr. Weir asked the Chairman if he would advise the operation in cases of simple fracture of the patella.

The Chairman said that he would not urge it, as he was not yet satisfied that the operation gave better results than had been obtained by other methods. But he would not hesitate to perform it on account of its being an unsafe operation.

Dr. Poore asked if there was not an impression among surgeons that the amount of motion was less after wiring than after treatment by other methods.

The Chairman thought that the reported cases thus far did not justify such a conclusion.

Dr. Poore believed that the lack of motion with any method was due somewhat to the condition of the flexor tendons.

A running discussion then took place, which was participated in by several members, and it terminated in the adoption of a motion empowering the Chairman to appoint a committee of three to report on the subject at some future meeting of the Section.

The Section adjourned.

The *Ensayo Médico* of Caracas is responsible for the following: "*To Darwinists.*—There has just been an interesting discovery in Paraguay of a tribe of Indians furnished with tails. One day a number of workmen belonging to Tacura Tuyu were engaged in cutting grass, when their mules were attacked by Guayacuyan Indians and some of them killed. The workmen pursued them and succeeded in capturing a little boy of eight years of age. He was taken to Señor Francisco Goleochoa at Posedas, and it was then discovered that he had a tail ten inches long, and has, in consequence, excited a good deal of interest. The boy says that he has a brother who has a tail as long as his own, and that all the tribe have tails."

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE GREAT MEETING OF THE COLLEGE OF SURGEONS—TRIUMPH OF THE MEMBERS—THE CO-OPERATION OF THE COLLEGE OF PHYSICIANS—THEIR MEETING—THE DEMAND OF MEMBERS—DISCUSSION.

London, October 31, 1885.

We have had a lively week in medical politics. Yesterday afternoon there was a magnificent meeting of members and fellows of the Royal College of Surgeons. It had been arranged that the Council would submit a report to such meeting, and the association of members was therefore active in seizing the occasion for maintaining its views. I have already informed you that the fellows have practically conceded the right of members to a share in the election of the Council. But the Council thereupon refused to recognize this principle. It is strange that men cannot see that educated members of a profession cannot always be debarred from a voice in the matters which concern them. The very title conferred, "member" of the college, is a standing rebuke to those who say members have no rights.

The meeting was held in the hall of the college. It is many years since such a privilege has been granted, and members from all parts of the country crowded the building. Mr. Sampson Gamgee came came up from Birmingham to take part in the proceedings. He is a capital speaker, a man much respected, and a thorough-going medical reformer. He took part in the meeting above mentioned many years ago, and the survivors of his then fellow reformers were delighted to again welcome him. Alas, how many of the company of the former fight were missed in this, and of those present what a change had come over them! Those then youthful looking are now old and gray, some infirm and decrepit, and some, though known to be alive, were unable to get out. Mr. Gamgee himself is much older, though he retains a good deal of his elasticity and is zealous as ever. He moved "that the Council of the Royal College of Surgeons, not having accepted the principle that members, as well as fellows, should take part in the election of the council, in the opinion of this meeting steps should be at once taken to memorialize Parliament and the Crown, so as to secure, in the interests of the public and the profession, the right to representation in the administration of affairs of the college for its 16,000 legally-qualified members."

A series of speeches followed, but it can scarcely be said that any discussion took place, as all the speakers were of one mind on the subject. No one had anything to say against the resolution, and it was adopted with much enthusiasm.

Then followed another resolution, "That in the opinion of this meeting no alteration in the constitution or in the relation of the college, or in any of its by-laws, or ordinances, shall be effected without the consent of the fellows and members convened to discuss the same." This resolution was also carried unanimously, and it was then proposed to adjourn until November 19th to receive the Council's reply, but the president ruled this *extra vires*, it is difficult to see why, as the right of adjournment is generally held to be inherent in every lawful assembly. However, a compromise was effected, for after a word or two with some of his colleagues, the president promised that another meeting should be called without unnecessary delay.

Thus the first campaign was won, and as the college wants a new charter and must get one for the contemplated conjoint action with the sister college, the members now have every opportunity of gaining representation, if they act together and agree to oppose any charter in which their rights are ignored.

A word about the report presented by the Council. It shows 16,723 members on the roll, and 1,153 fellows, and yet this little body of fellows has previously held the only privilege, that of electing the Council. During the past year 113 candidates went up for the first examination for fellowship, 64 of whom were rejected, and 56 went in for the final examination, 19 failing. For the membership there were 1,258 candidates at the primary examination, and 960 at the final. The rejections were 705 and 397 respectively. The fees paid by members constitute the main income of the college, and will certainly diminish if justice be any longer refused.

The College of Physicians, as I have already informed you, has by a large majority passed a resolution that persons examined by the two colleges should have a degree in medicine and surgery conferred upon them. Steps will be taken at once to secure for the joint colleges the necessary right, either by charter or act of Parliament. In either case the members will be able to present their grievances to the Government, and may probably obtain redress. Sir R. Bennett, and a few others opposed the movement, and thereby showed their want of breadth more decidedly than ever. Sir R. Bennett, as one of his intimates says to me, was always a "weak man," and weak men, we all know, are apt to have strong prejudices in favor of the paths of their childhood. Sir W. Jenner supported the proposed advance heartily. He is reputed to be a strong man, and I used so to regard him, but his lamentable weakness in the matter of the college fellowship has gone far to annul the notion. Unless he goes carefully through the list and sees that London lecturers are not passed by to make room for personal friends or clients, his present term of office will have done much to deprive him of the respect he has long enjoyed as an honest and liberal-minded man.

It is justice, not favoritism, on which an upright man's reputation as a ruler should rest, and Sir William Jenner is a ruler in his college, and we may well look to him when advocating advance, to repair the injustices of his predecessors and—yes, of his own previous official career.

Unless this is done the members will follow the example of the members of the sister college, and the two institutions may find themselves face to face with an enraged constituency having the ear of the Government and denouncing the proposed united action as a job intended to put money in the coffers of the colleges and the purses of some of the officials.

YELLOW FEVER AND THE EFFICACY OF QUARANTINE.

To the Editor of The Medical Record.

Sir: In the September number of the *Sanitarian*, the editor writes: "If the case of the bark John Gibson," from which a case of yellow fever was introduced into New York city, on August 18th, "is a fair example of the administration of quarantine at Delaware Breakwater, it is evident that no protection is afforded by it to the cities on the Delaware, or anywhere else, and the sooner it is abolished the better. A vessel that has been 'cleaned and fumigated,' and communicates yellow fever within a week thereafter alongside of the wharf of a populous city, in midsummer, is a dangerous specimen of sanitary service." The spirit in which the above was written is apparent by referring to the August number of the same journal, where, referring to the same case, the editor fails to recommend the abolition of the New York quarantine, through which he at first supposed the bark passed. The facts of the case are as follows: Shortly after July 16th, on which date the bark John Gibson left Cienfuegos, the mate developed yellow fever. During the voyage to Lewes, Del., five persons, of the fourteen on the vessel, had yellow fever. One case was fatal.

At Lewes the vessel went into quarantine, Acting Assistant-Surgeon W. P. Orr, of the United States Marine Hospital Service, being in charge. She was thoroughly fumigated, detained in quarantine from August 3d until August 12th, when, no further apprehension existing, she was allowed to sail for New York, where she arrived August 14th.

Acting Assistant-Surgeon Orr gave her a clean bill of health, which was referred to Health Officer Smith for personal inspection. It was publicly stated that he decided that it would be safe to honor the bill of health, but took the precaution to fumigate the vessel again.

On August 18th one of the discharged seamen of the vessel developed yellow fever, of which he died the next morning.

For eleven days this man was under observation, and yet he presented no symptoms of yellow fever. While we will not enter into any discussion of the length of time necessary for yellow fever to develop after exposure, still we cannot entirely believe it was from materies morbi still in the vessel. If so, the fumigation received in New York was as useless as that at Delaware Breakwater.

I have desired to make this public record of the case, because the Health Officer of the port of New York saw fit to make some unprofessional remarks regarding the officer at Delaware Breakwater. In consideration of the fact that five cases of yellow fever passed the New York quarantine between the last of August and October 1, 1884, it would seem that the officer in charge might understand the fallibility of quarantine.

Very respectfully,

S. T. Armstrong,

Passed Ass't Surgeon U. S. Marine Hospital Service.

Memphis, Tenn., September 28, 1885.

PROGRESS IN MEDICAL EDUCATION—THE WOMEN TAKING THE LEAD.

To the Editor of The Medical Record.

Sir: As your columns are constantly open to notes of progress made in medical education, you will permit me to mention a detail in regard to that of the Woman's Medical College which is not generally known. This is the complete separation which has for several years been established between the courses of study in therapeutics and in materia medica. During the first year no students are permitted to study therapeutics or the action of drugs, it being theoretically absurd to suppose that this could be understood, in either health or disease, while as yet no study had been made of either physiology or pathology. But during the first year the students follow a special course on materia medica proper, under the direction of a separate professor (Professor Josephine Chevaillier). This course relates to the botanical, chemical, and pharmaceutical properties of drugs, which are not only described in systematic lectures, but handled, analyzed, dissected, and manipulated, during four months of laboratory work. The work done by the class in the last year may be estimated from the subjoined programme of laboratory work.

I think it worth while to call attention to this feature of our course, for it is an entirely original one, and entirely peculiar to our school, yet it is certainly eminently rational; and has been highly praised by so great an authority as Hoppe-Seyler, to whom Professor Chevaillier recently described it.

Practice in Chemistry.—The first four months which the first-year students spend in my laboratory are devoted to a course in qualitative analysis.

First, they acquire a knowledge of the processes by working on known bodies and mixtures of those bodies, which the student makes herself; and then analysis of unknown substances, and these are anything that may fall into my hands, such as residues from lecture-table apparatus, gall-stones, calcined bone-black, cosmetic powder (sent for analysis by Dr. Cushier), the tinted chalks, solder, one-half per cent. solution each of oxalic acid and sodium chloride (they are always puzzled by these!), mixtures of solids containing as many as ten or fifteen substances to be detected—acids and bases, etc. The laboratory work is accompanied by written examination on the groups in qualitative analysis, before the student begins the work on the group with unknown substances.

Practice in Materia Medica, 1885.—Microscopic work: Yeast, bacteria, starch grains, vegetable tissues, formic acid (from glycerine and oxalic acid), ammonium acetate, magnesium sulphate, zinc sulphate, opium suppositories, extraction of morphine from opium, acetic ether, oxalic acid, testing for alkaloids, oxide antimony, aq. camphoræ, aq. cinnamomi (distillation), aq. cinnamomi (with $MgCo_3$), arsenic iodide, ferric chloride, dialyzed iron, reduced iron, iodoform; mercuric oxide, chloride, iodide, turpeth mineral: mercurous oxide, chloride, iodide; yellow iodide mercury; red, yellow, and black wash, $Hg(Ch)_2$ (mercuric cyanide), Monset's solution, tersulphate iron, zinc delphinium, test for cod-liver oil, pil. antimonii compositæ, citrion ointment, reduced iron, fluid extract rhubarb, Fowler's soluton.

Mary Putnam-Jacobi, M.D.

110 West Thirty-fourth Street.

SPONTANEOUS ORIGIN OF TYPHOID FEVER.

To the Editor of The Medical Record.

Sir: I see by The Record that the Academy of Medicine has discussed the question as to the possibility of the "spontaneous origin of typhoid fever." To avoid a tedious discussion and loading of your columns, allow me to state briefly that the question is forced upon the attention of the practitioner of the Rocky Mountain region, as well as of the adjacent plains, by the presence of what in former days, when the country was sparsely settled, was called "mountain fever." It obtained its name from the fact of the early explorers scattering in isolated parties during the summer months in the mountains along the streams in search of gold, and while so employed would be attacked with a continued fever; and as they did not have the "antecedent case" of the old settled communities—the convenient milkman, or the sewer and its priest, the plumber—to explain the origin of the fever, and as the teachings of the colleges required that there should be certain environments in order that there could be a case of typhoid fever, the disease was termed "mountain fever." Not that it necessarily originated in the mountains, because we find it all over the country, and under sanitary surroundings that could not be equalled in perfection anywhere else on the continent.

In my opinion, it is impossible for physicians to settle the question as to the spontaneous origin of some diseases as long as they remain in old settled communities, where the modes of communication are so varied.

The antecedent case of that year, or the year before, can generally be found, and the methods of communication are at hand. But let the same gentlemen come out to a new country, where the patient is not under these sanitary surroundings, as I did in 1872, and see patients, children who have not been away from home, adults who have been isolated for months in some mining cabin, or a ranchman off on his ranch "baching it," and not a neighbor nearer than ten or twenty to thirty miles, and see the disease pursue its fatal course with all the symptoms of typhoid fever, examine the eroded intestines, and the question of the spontaneous origin of typhoid fever would be settled so far as his individual opinion goes.

If typhoid fever depend upon a bacillus, then that bacillus is as thoroughly disseminated as the spore of the yeast-plant, that is always on hand when sugar and water

are mixed in the right proportions and the temperature is at the right point for its development.

In this country, dry weather seems to be a factor in the development of typhoid fever. A rainy spell will check its progress. This I have seen in Northwestern Texas: typhoid fever during dry weather, and ague during wet weather, the ague succeeding to the typhoid fever, both in the same season.

That the so-called mountain fever of the Rocky Mountain region is a typhoid fever, there can be no reasonable doubt in the minds of the early physicians still remaining in the country, and that mountain fever is of spontaneous origin, everyone who has had experience in the treatment of the disease will agree to.

I do not bring these arguments forward as new: the early writers recognized the similarity of the lesions in "mountain" and typhoid fevers. Hammond speaks of it, and Smart recognizes it (if I am not mistaken), but tries to reconcile the prevalent theories about typhoid fever and the fact of the spontaneous origin of mountain fever by claiming malarial origin, caused by water containing vegetable matter brought down from the timber line with the melting snow; but in this section the vegetable matter contained in the water of our mountain streams is a myth. I have kept the water bottled for years without decomposition or odor, and with but a very slight cloudiness in the slight sediment, and have examined the water for vegetable substances, but after evaporating the water there was next to no organic matter in the residue.

In old settled communities there is no doubt but that typhoid fever is a much severer disease than we usually find it to be in the country regions of Colorado, our larger cities in Colorado having all the conditions for the intensification of the disease, and in them the disease is severer. On page 547 of the "National Board of Health Bulletin" (1881), I state that I believe that "typhoid fever can be caused by a poison generated within the body of the patient (ptomaines) under the best circumstances of drainage, food, and water supply, healthy locality, and *absence* of contagion. The disease thus originated may be intensified, and communicated by infection or contagion to other persons, defective sanitary and hygienic conditions, of course, favoring such transmission."

Colorado is now, in the eastern portion, too well settled to prove much about the spontaneous origin of typhoid fever, even admitting the identity of mountain fever with typhoid, because the antecedent case has occurred, and those holding to that theory can, as in New York, prove anything. But in an early day, before the advent of railroads, the antecedent case was not on hand; then three, four, or more miners started out to prospect a gulch mine, and remained isolated all summer. During the fall, one of their number would be attacked with "mountain fever," or the ranchman who had not been to town for months was taken with a fatal attack of the dreaded mountain fever, even when he had not been near the mountains.

All that is now changed in this part, and it is to the older and earlier practitioners that we must turn for information.

Yours truly,

CHARLES AMBROOK, M.D.

BOULDER, COL., November, 1885.

THE PAY PATIENT ABUSE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I have read with interest the editorial, "The Pay Patient Abuse," which appeared in THE MEDICAL RECORD of November 7th. It is indeed a question of the day, and one which comes very close to physicians. That patients can receive medical attendance or enjoy the benefits of surgical operations, simply for the price of board, is a monstrous injustice to those who are faithfully and diligently following the practice of their profession.

Is it not time that *lawyers* contributed their share to the public welfare? Why should there not be some public institution, where for a mere nominal fee, enough to support the establishment, say, the best lawyers in the city should be approachable for free consultations at stated intervals?

There is a screw loose somewhere. The whole system needs readjusting. The more opinions are ventilated in regard to this matter the better it will be and the brighter the hope for its adjustment.

I remain, yours truly,

A READER OF "THE RECORD."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: As often as a problem has been presented for solution, so often has it been remarked that there are two sides to a question. Apropos of this, I wish to respectfully call your attention to the opposite argument in reference to what you were pleased to call, in an editorial occupying a prominent place in the columns of a recent number of THE MEDICAL RECORD, "Pay-Patient Abuse."

The occupation of the positions of, in turn, resident physician, and attending physician, of hospitals, is a voluntary one; nay, more, these posts are sought after with fierce competition. The physicians receive ample compensation for their time and services in experience and fame. If those at present occupying such posts do not feel so, they do great injustice to the numerous aspirants waiting with longing expectancy for a vacancy.

Possibly it is unjust to the majority of those toiling in the profession that an inducement to enter hospitals is held out by the comparatively small charges, which include no physician's fees, but the hospital staff are not the ones to complain. They have bargained for experience as their honorarium, and they get it. When it is an insufficient recompense, then the position should be vacated to one of the many who will be glad of it.

If the trustees of hospitals should exact medical fees, ought not these to belong to the physician who places the patient in the institution?

I remain, yours obediently,

A HUMBLE ASPIRANT FOR A HOSPITAL APPOINTMENT.

THE TREATMENT OF MASTITIS BY REST AND COMPRESSION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I have been somewhat interested in the controversy which has taken place between Dr. Milroy, of Omaha, Neb., and Dr. Harris, of Paterson, N. J., relative to "the treatment of mastitis by rest and compression." I am somewhat surprised at the claims which these gentlemen set forth, as to priority of treatment of mastitis by compression, either with adhesive straps or by the bandage; and I am more surprised to learn that Professor Mundé has taken the field as the champion of Dr. Milroy's claim. In the July number of the *Western Medical Reporter* for 1881, Dr. Oppenheimer, of Seymour, Ind., says: "I have been unable to discover the name of the originator of this method of strapping the breast in mastitis, but his name certainly deserves to be written high as a benefactor to women." I desire to call your attention to a paper upon this subject, by Dr. George E. Ranney, of Lansing, Mich., which was published in the Detroit, Mich., *Review of Medicine and Pharmacy*, in June, 1866, p. 99, and in order that there may be no mistake, I inclose a *verbatim* copy of the paper.

At a meeting of the Michigan State Medical Society, held at Bay City, June 8, 1881, in the discussion of this subject, in reply to Dr. Johnson, of Grand Rapids, who

recommended rest and light cool dressings, Dr. Ranney again explained his method of compression as follows:

"In 1866, I published, in the June number of the *Detroit Review of Medicine and Pharmacy*, an article detailing a method I had adopted for the treatment of congested and inflamed breasts, and for the prevention of the secretion of milk when, on account of a still-birth, or death of the child after delivery, or for any other reason, I wished to diminish the augmented activity of the circulation, the tendency to tumefaction, inflammation and its results, or to arrest the secretion of milk in the mammæ. This method consisted of pressure on the distended glands by means of a bandage.

"Since the publication of that article I have had frequent opportunities to test its efficiency, and in every instance where extensive exudation had not occurred, have applied the bandage to the great relief and comfort of the patient and satisfaction to myself. In fact, I feel as though I had got a perfectly sure, efficient, and simple means of absolutely controlling the distressing difficulty.

"In selecting a bandage I take a strong piece of cotton cloth sufficiently wide to reach from the axilla to below the tumefied glands, and long enough to reach around the chest and tie at the ends, which should be 'many-tailed.' The ends should be tied over the sternum, and by the many-tailed arrangement it may be tightened at short intervals, and at one sitting at the bedside, as the engorgement will rapidly diminish under the pressure thus applied. In many cases it may be necessary to place napkins or sponges between the mammæ to complete the rotundity and equitable pressure."

I send you by this mail a copy of the "Transactions of the Michigan State Medical Society" for 1881, and I beg to refer you to page 18 for the above quotation. I do not wish to in any way detract a single iota of praise which may be bestowed upon the originator of the treatment of mastitis by compression. We are all seekers after truth in the vineyard of medicine, and if Dr. Harris or Dr. Milroy, or some other person, cannot give us some facts, and proof of originality, which antedates the paper of Dr. Ranney, I can see no other way than for them to accord the originality of treatment of mastitis by compression to that gentleman.

I am aware that Dr. Ranney, since my acquaintance with him, now nearly five years, has practised this method of compression, and recommended and proclaimed it on every suitable occasion.

JULIUS A. POST, M.D.

208 SOUTH WASHINGTON AVENUE,
LANSING, MICH., October, 14, 1885.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 8, 1885, to November 14, 1885.

BAILY, E. I., Colonel and Surgeon. Relieved from duty as Attending Surgeon, San Francisco, Cal., and ordered for duty as Medical Director of the Division of the Pacific and Department of California. S. O. 260, A. G. O., November 11, 1885.

NORRIS, BASIL, Lieutenant-Colonel and Surgeon. Ordered for duty as Medical Director of the Department of the Columbia. S. O. 260, A. G. O., November 11, 1885.

MCKEE, J. C., Major and Surgeon. Ordered for duty as Attending Surgeon and Examiner of Recruits, Boston, Mass. S. O. 260, A. G. O., November 11, 1885.

VOLLUM, E. P., Lieutenant-Colonel and Surgeon. Ordered for duty as Medical Director of the Department of Texas. S. O. 260, A. G. O., November 11, 1885.

SMITH, J. R., Lieutenant-Colonel and Surgeon. Ordered for duty as Attending Surgeon at New York City, N. Y. S. O. 260, A. G. O., November 11, 1885.

ALEXANDER, R. H., Lieutenant-Colonel and Surgeon. Ordered for duty as Medical Director of the Department of Arizona. S. O. 260, A. G. O., November 11, 1885.

KANE, JOHN J., Captain and Assistant Surgeon. Ordered for duty as Post Surgeon, Fort Ringgold, Tex. S. O. 141, Department of Texas, November 4, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 14, 1885.

SAYRE, J. S., Assistant Surgeon. Detached from Naval Hospital, Mare Island, and ordered to the Omaha.

DIXON, W. S., Surgeon. Detached from Coast Survey steamer Hassler upon reporting of his relief, Passed Assistant Surgeon D. O. Lewis, and wait orders.

LEWIS, D. O., Passed Assistant Surgeon. Detached from Naval Rendezvous, San Francisco, and ordered to relieve W. S. Dixon, steamer Hassler.

DUNGAN, J. S., Medical Director. Ordered to Naval Rendezvous, San Francisco, to relieve Passed Assistant Surgeon D. O. Lewis.

Medical Items.

THE GLASS-EATER A FRAUD.—Dr. T. E. Murrell, of Little Rock, Ark., writes us that the glass-eating negro whose case was reported by Dr. Burke is a humbug.

MEDICAL OFFICES in this city, with reception room privileges, command a rental of from fifty to one hundred and fifty dollars per month, according to locality.

RECENT LEGAL DECISIONS ON MEDICAL MATTERS.—The Second Comptroller of the Treasury, Judge Maynard, has charge of pension matters and occupies a semi-judicial position in regard to the proper construction of the law. Section 4718 of the United States Revised Statutes contains the following paragraph: "If any pensioner has died or shall hereafter die; or if any person entitled to a pension, having an application therefor pending, has died or shall hereafter die, his widow, or if there is no widow, the child or children of such person under the age of sixteen years shall be entitled to receive the accrued pension to the date of the death of such person. Such accrued pension shall not be considered as a part of the assets of the estate of the deceased, nor liable to be applied to the payment of the debts of said estate in any case whatever, but shall inure to the sole and exclusive benefit of the widow or children; and if no widow or child survive, no payment whatsoever of the accrued pension shall be made or allowed, except so much as may be necessary to reimburse the person who bore the expenses of the last sickness and burial of the decedent in cases where he did not leave sufficient assets to meet such expenses." The latter part of this paragraph came before Judge Maynard to decide as to the meaning of the phrase "last sickness," under the following circumstances: An old soldier named Mark Newman died in August, 1884, while his application for a pension was pending but undecided. It was granted in October, 1884, and it was decided that there was due him $2,439. He left no widow or children, and consequently, under the Statute, there was nothing payable except what was sufficient to reimburse the person who bore the expense of his last sickness and death. The pensioner had lived at the house of John Parsons during part of the time between his discharge from the Army in 1864 and his death in 1884, and the event took place at Mr. Parsons' house. The latter put in a claim to the Pension Office for $4,401 for expenses incurred during the last sickness and burial of Newman, upon the theory that the injuries received by him in the service of his country were so serious and permanent that the whole period of twenty years was to be regarded as his "last illness." The claim was once passed upon by the accounting officers of the Treasury, and allowed

in January, 1885, to the full extent of the pension, viz., $2,439. The case then came before the Second Comptroller, who decided that the phrase "last sickness" had always been limited to that which was the immediate cause of death, and could never be applied to a long period of disability, as in this case, from which no fatal results were to be immediately apprehended. For this reason the claim made by Parsons was disallowed, and instead he was granted, for expenses of board, nursing, and care of Newman, $320; for bill of physician, $92, and for funeral expenses $57, or $469 in all.—A Connecticut graveyard was recently disturbed and three old graves opened to enable an English gentleman to see if any of them contained a signet-ring, which was necessary to prove certain impressions on seals. It seemed that an important link was wanting in the settlement of an English estate, and the production of the ring would determine the succession to the property. A careful examination was made of the graves, but without finding the much-desired ring.—One of the Boston telegrams recently contained an amusing story of the examination of a witness. It appeared that a liquor trial was going on in a police court at the same time that an examination was to be held at Police Headquarters for appointment on the police force. By some misunderstanding a witness in the liquor case was admitted to the room containing the applicants for police positions. The sergeant in charge supposing that he desired to be examined physically, ordered him to remove his clothes. He appeared to be greatly surprised, and asked if that was necessary. He received an affirmative answer, and as several others in the room were doing the same thing, he followed their example. In a few minutes the physician came to examine him, and made a very thorough business of it. The face of the witness was all the time a curious study. He was evidently trying to determine what connection there was between his bodily condition and his evidence in the liquor case. All doubts were dispelled, however, when the physician remarked, casually: "So you want to be appointed on the police force, do you?" The man jumped as if he had been struck. "Mein Gott, no, I don't!" he yelled. The spectators say that he beat the record in getting inside his clothes.—A Michigan Court has recently had before it a case involving a contract made by a drug establishment not to sell certain pills below a certain price. Such a contract the judge held to be valid, on the ground that pills, unlike wheat and other articles of food, were not necessaries of life, and so not contrary to the rule which forbade, for reasons of public policy, contracts to raise the price of food artificially. The judge enunciated the startling opinion that the assertion that pills were "in any sense indispensable to the human race would be a violent presumption, not to be entertained judicially, and only to be established by evidence which every sensible man knows has no existence." The learned judge in thus attempting to annihilate a whole trade forgets that pills are indispensable to the druggist and to the patent-medicine manufacturer, if to nobody else. This extensive class of people are most positively of the opinion that the safety of the world depends upon the unhampered manufacture and sale of pills.

Concerning Points in Bacteriology.—Dr. Alfred C. Haven, of Lake Forest, Ill., writes: "I have read with pleasure the 'Lecture on Bacteriology' of Dr. Loomis, published in The Record of October 24th. While I would not presume to criticise so distinguished a savant, I cannot but notice a few statements which seem to be contradicted by other authorities, and would appeal to The Record as a referee. Is it definitely settled that bacteria belong to the *fungi*? does not Cohn, whose classification Dr. Loomis accepts, regard them as belonging to the *algæ* (vide Sternberg's 'Bacteria,' page 21)? Did not Nägeli first classify them as schizomycetes, not Cohn (Sternberg, 'Bacteria,' page 22; Klein, 'Micro-organisms in Disease,' page 34)? Dr. Loomis also says: 'Certain forms are found in the blood of *healthy* persons.' Dr. Sternberg writes: 'I have, therefore, come to the conclusion that bacteria do not occur in the blood nor in the tissues of the healthy living body, either of man or of the lower animals' ('Bacteria,' page 261). Another author writes: 'It is now admitted by most competent observers that in the healthy and normal state the blood and tissues contain no micro-organisms whatever, and that the assertions to the contrary are due to errors in the experiment, *i.e.*, to accidental contamination' (Klein, 'Micro-organisms in Disease,' page 176). Pasteur is credited by his son-in-law with the following: 'In 1863 he had established that the bodies of animals in full health are sealed against the introduction of the germs of microscopic organisms' ('Louis Pasteur,' by his Son-in-law, page 184). Dr. Loomis also writes: 'Pasteur, experimenting with the bacilli of anthrax, found, by exposing the microbes to a certain temperature higher than the most favorable for their development, they lost their virulence to such an extent that he could vaccinate sheep without danger.' In reading the 'Life of Pasteur' we do not find stress laid upon *temperature*. 'The *oxygen* of the air, then, appears to be the cause of modification of the virulence of the microbe' ('Life of Pasteur,' page 225). The virulence is diminished by exposure to the oxygen for a sufficient length of time. Finding difficulty in harmonizing these statements, I would simply refer them to The Medical Record."

To Err is Human.—"Indeed, madam, I know all about it; I saw just what ailed the woman as soon as I came into the room. There is a young man up street who is sick the same way, and I am attending him. Give the medicine as directed, and I will call around in the morning." Having delivered himself thus the young doctor took up his hat and departed. Not long after this, the pains having come on again with increased rigor, another messenger was hurried off for the old doctor, who was found just returning from a far-out call. The young doctor, upon coming over in the morning, expressed much pleasure at the supposed result of his treatment, and was rubbing his hands with an air of "I never make any mistake," when the nurse, turning down the bed-coverings, discovered to him the little one lying on his mother's arm, as she said: "By the way, doctor, has the man up street got through yet?" The moral is obvious: Do not be too previous in your diagnosis.

The Kleptococcus.—We learn with pleasure that Professor Meandra has succeeded in isolating the bacillus of kleptomania. It has long been thought that this disease owed its origin to an organism of a snaky, elusive nature, which rendered detection difficult, but it remained for Professor Meandra to first demonstrate its existence. The difficulty was, of course, to obtain pure cultivations. At length Professor Meandra secured a magpie of well-known thievish propensities, and removing a small portion of its brain, under the spray, he began the first of his long series of experiments. The organism can be readily grown in beet-juice (prepared by beating beets and straining) or in cabbage-infusion. It stains easily of a deep steel color. Under a power of eighty diameters this organism presents a hook-shape, thus ?, which gives it the name of Meandra's Interrogative Micrococcus; we would, however, suggest (with due deference to the professor's taste) the name of hookey-coccus, both as more euphonious, and as applicable, no matter what position the organism may assume; it also indicates its character as well as shape. Injected subcutaneously into cats the effects of the hookeycoccus were remarkable. Several of these animals, let loose in a back-yard, were seen two days after to creep surreptitiously into some of the neighboring houses and kleptomize pieces of meat, fish, etc. While we cannot quote the whole of this important article, we relate one interesting event. A quantity of beet-juice, in which a cultivation was far advanced, was spilled on the floor of the

laboratory. Three days after the professor missed his pocket-book, watch, and other articles of value; it was also noticed that several houses in the place had been visited and valuables taken. Mr. Lestees, the professor's assistant, a man of the highest respectability, was also missing. Professor Meandra thinks he must have inhaled some of the dry dust from the spilled cultivation. There was much excitement when the affair leaked out, and, as there are two banks in the town, the people petitioned the mayor to prevent all communication between the professor and the cashiers. There is no doubt that an attenuated cultivation can be obtained, in which case the criminals confined in the prison at Moros will be vaccinated. We agree with this great investigator when he says, "the bacillus opens a wide field for thought—an almost unfathomable vista." "Many generations must pass," he continues, "before the last microbe is stained and mounted, drawn and photographed, and stamped with the name of its discoverer." "The next two hundred years will be known in history as the Microbian Age."—*The Birmingham Medical Review.*

The Megaloscope.—Baron Larrey recently presented, in the name of Dr. Boisseau de Rocher, to the French Academy of Sciences, a new apparatus under the above title, for exploration of the bladder, rectum, œsophagus, and stomach. The name is derived from the Greek words, μεγας, great; εικων, image; σκοπέω, to see. The mechanical part is composed of a sound carrying at its extremity, for bladder exploration, a lantern containing an incandescent lamp for illumination of the cavity. That for the stomach is formed by a sound in which another sound glides carrying an objective, and the movements of which are regulated by special mechanism. By means of the objective an image is obtained, and the interior of the cavity can be studied. As it exposes a diameter of twenty centimetres, the objective lens presents an image which is magnified by the megaloscopic lens.

Human Electrotypes.—M. Kergovatz, a chemist of Brest, has, says the *Scientific American*, proposed a new method of disposing of the human body after death, which he considers preferable in every way to either burial or cremation. His system is an antiseptic one, much simpler and less expensive than the old process of embalming, and is nothing more than a new galvanoplastic application. The body is coated with a conducting substance, such as plumbago, or is bathed with a solution of nitrate of silver, the after-decomposition of which, under the influence of sunlight, leaves a finely divided deposit of metallic silver. It is then placed in a bath of copper sulphate, and connected for electrolysis with several cells of a gravity or other battery of constant current. The result is, that the body is incased in a skin of copper, which prevents farther change or chemical action. If desired, this may again be plated with gold or silver, according to the taste or wealth of the friends of the dead. M. Kergovatz has employed the process eleven times on human subjects, and on many animals, and states that in all cases it was perfectly satisfactory. In spite, however, of his warm recommendation, the idea, our contemporary thinks, is repulsive. It seems a mockery to give permanence to the temple, when all that once made it valuable is gone.

Penis Captivus.—Our esteemed contemporaries, all the world over, have been making merry over a case of supposed vaginismus reported some time ago by Dr. Egerton Y. Davis, in a Philadelphia journal, and some of them have not attempted to conceal their incredulity. The case was one of a coachman caught in *flagrante delicto*, whose efforts to extricate himself from his predicament, when discovered by his master, were a dismal failure. Most of the journals which noticed it remarked that it was a good story for the dog-days; but now, Dr. Liebrecht comes to the rescue of the reporter's reputation for veracity. He writes, in a recent number of the *Journal d'Accouchements*, to the effect that the case was not one of vaginismus, for that prevents the act of copulation, but rather of contraction of the levator ani muscle. And he states that several cases of this sort have been reported by Hildebrandt, Budin, and others, the present one differing from them only in the persistency of the spasm.

Premature Rupture of Membranes.—Dr. F. L. Putt, of Middlebury, Ind., writes: "Please permit me to say to Dr. R. M. Cole, of Idah Springs, Cal., that in his case of premature rupture of membranes he does not state if any water escaped when true labor did come on. On the presentation I have quite frequently met with cases where there was dropsy (so to speak) of the membranes covering a fœtus, which passed away one, two, or three weeks before true labor came on, and when labor did come a normal quantity of fluid escaped; again, where the fœtus assumes a malposition, with feet or knees to appear, the membranes are ruptured in a valve shape and all the water escaped with no expulsion pain. In such cases prudence dictates patience, and the wise and frugal practitioner sits by and consoles the expectant mother to give herself no worry, as such accidents are more of a relief than a source of anxiety."

The Compound-oxygen Humbug.—Oxygen has a very narrow range of therapeutical utility, however applied. It is somewhat curious that a special oxygen or compound-oxygen treatment has been able to gain so much support and extract so much money from a credulous public. Regarding this matter, Dr. Wm. B. Clarke, of Indianapolis, Ind., sends us an account of the way in which he was deceived by a person of whom he had bought an "oxygen-plant." The person in question claimed that the formulæ were the same as those used by the quacks Starkey and Palan. The following are the formulæ, *verbatim*: "Comp. Oxygen Treatment: ℞. Citrate ammonia, 25 parts; carbonate ferri, 1 part; mix, put in retort, apply gentle heat till whole compound comes to a boiling heat, then add heat gradually, and conduct oxygen to the tank. Home Treatment of Oxygen: ℞. Nitrate ammonia, 1 ounce; chlorate potassa, 1 drachm; alcohol, 2 ounces; aqua distilled, 14 ounces; mix; one teaspoonful to inhaler full of hot water; inhale two or three times a day." By the first formula, says Dr. Clarke, nothing is produced but laughing gas, and this is the real compound oxygen. The carbonate of iron is of no chemical import. By the second formula nitric oxygen or nitrous oxide is evolved. The exhilarating effects of nitrous oxide, and its stimulating effect in the treatment of certain nervous conditions, may account for some successes.

A Hospital in the Morgue.—A Vienna journal relates that the authorities of a certain village wished to have a small-pox hospital, and being unable to find a suitable location, hit upon the morgue as being well adapted for their purpose. Accordingly they moved in a number of beds, and congratulated themselves on having secured a pest-house at small expense. They had no corpse and no patient at the time, but felt that they were ready for either, whichever might present himself first. But unfortunately the Austrian health officers heard of the new combination arrangement and vetoed the project, much to the disgust of the thrifty villagers.

Hæmostatic Pills.—The following formula is recommended by M. Huchard: Powdered digitalis and extract of hyoscyamus, of each three grains; ergotine and sulphate of quinine, of each thirty grains; make into twenty pills. From five to ten pills may be taken during the twenty-four hours in metrorrhagia, epistaxis, hæmoptysis, and other hemorrhages.

Glycerine as a Tænicide.—Maccallum, says that glycerine is an excellent anthelmintic. He gives it in doses of one ounce and follows it with a mild purgative. He was led to employ it from observing that tape-worms were killed by immersion in it.

The Medical Record

Original Articles.

PATHFINDING IN MEDICINE.[1]

BY HENRY D. NOYES, M.D.,

NEW YORK.

IN assuming the position which I occupy on this occasion, I comply with the request of our President, who invited me to take it in place of our esteemed and distinguished colleague, Professor Janeway, to whom it had been assigned, but who has been prevented by severe illness from fulfilling the office. On behalf of the Academy, and also in expression of my own warm feeling, I beg to utter the most sincere congratulations to him and to ourselves that his health and activity have been restored, and that we may still admire and draw upon his shining abilities and his stores of knowledge, his untiring industry and his willing helpfulness.

During the year past, it has been permitted me to see many medical men and medical institutions in various parts of Europe. One gets a new impulse from such an opportunity, and one may also be lifted to a wider horizon in the field of medicine. The privilege of attending the great International Congress at Copenhagen, and also the smaller but no less interesting annual Ophthalmological Congress at Heidelberg, could scarcely fail to ennoble one's view of the science and practice of medicine. The impression which, to me, has come uppermost, is that the line of advance must hereafter be through acute, exacting, and deep research. How little did the centuries contribute to correct knowledge of disease so long as only our unaided senses were employed! What an epoch arose when physical diagnosis began to be cultivated! How steady has been the advance, and how rich the treasure of facts, since means of physical study and examination have become more complete and numerous! We supplement the eye by the microscope, the ophthalmoscope, the laryngoscope, and the spectroscope; we augment the hearing by the stethoscope; we read the pulse by the tracing of the sphygmograph; we test muscularity by the dynamometer; we take the weight on the scales; we take the temperature by the thermometer and record it on charts; and we determine the quality of nervous and muscular reactions by the galvanic current.

Physiology has for many decades been a science founded on experiment; pathology has been rapidly pressing forward in the same direction. To read the account of how certain conclusions have been arrived at in the laboratory, by ingenious devices, and by skilful manipulations, is as fascinating as a tale of adventure. A modern laboratory for medical research is equipped with apparatus and means of experiment to a degree which creates something akin to the feeling of awe inspired by a great astronomical observatory. Chemistry, mathematics, physics, applied optics, the deft hand, the keen eye, the quick ear, the delicate touch, all are taxed to solve these subtle problems. In such a place the ordinary medical practitioner may think that he sees nothing which has any special importance to him or to his daily calling.

What relation exists between laboratory experiments and the routine of measles and childbed and pneumonia, *et id genus omne*, is perhaps unintelligible to some solid practitioners; but many a shrewd physician will admit that he is sometimes greatly puzzled by the cases which he meets, and he would like to better understand the true nature of the morbid process whose phenomena he is watching. He has learned to rely on certain drugs and therapeutic methods, he would gladly know the true affinities of these agents, and how they accomplish their work. If you tell him that a dose of iodide of potassium produces certain results according to certain laws of molecular physics, he knows that he has heard that phrase; but to trace those laws demands the laboratory with an extensive equipment, and a man to work in it who has large attainments and commanding talent. The value of good clinical observation is not to be depreciated, it must always take high rank in practical medicine; but it cannot lead far in the path of scientific medicine. We may at this day almost say that clinical observation has wrought the consummation of its work. This may not be true in the department of therapeutics, as witness cocaine, jequirity, nitro-glycerine, convallaria, and so forth. But in knowledge of the essential nature of disease, of its causation, of its prevention, and of how medicines exert their effect, and, in some measure, by what rules they are to be chosen—for all this clinical observation must be supplemented by the laboratory. I must guard myself against being misunderstood. It must be noted that I do not speak of the instruction of students, or of young practitioners. Neither do I disparage the advance in knowledge which every good practitioner gets from long experience. Much valuable knowledge is locked up in the mental storehouses of shrewd practitioners, which dies with them. It sometimes happens that important discoveries are made several times, by different individuals, before they get into the current of common knowledge. A great clinical teacher contributes not a little to the sum of truth from his own observations. The lectures of Trousseau and of Nélaton were a delight and a treasure to their listeners. But if I were to call upon our own eminent clinicians to tell us the sources whence they draw their deepest draughts of wisdom, we should hear them tell how they have sought explanation of morbid phenomena, their sequence, their mutual dependence, and their origin, in studies which have been made by the microscope, by analysis of the blood, of the urine, and of the tissues; they have called in the subtle aid of organic chemistry, they have resorted to the breeding oven, and to cultures upon gelatin. In other words, they have been working in their private laboratories, and they pride themselves on their ability to supplement their own fine senses and perceptions by these additional methods of research.

The activity which at the present time pervades our profession in zealous pursuits of this description, displays itself in all our medical journals. Our American physicians may be justly proud of their forwardness and energy in such efforts. The wonder is, that they do so much with the meagre facilities which are at their command. I pay willing tribute to men who sacrifice ease and health to pursuits of pure science; who must snatch time from bread-getting, who give public instruction, whose is the heroism of steadfastness and unshrinking labor, that they may contribute to the advance of scientific medicine. You will acquit me of any thought of belittling the achievements and aspirations of my brethren, if I venture to bring before you the need there is among us

[1] Anniversary Address delivered before the New York Academy of Medicine, November 19, 1885.

for better and more perfect methods of pursuing scientific medical research.

The conviction of the inadequacy of simple individual efforts to carry us much farther forward in medical attainment has led to the establishment of concerted efforts in the study of disease. It is proposed to gather together multiplied observations in the same diseases, and endeavor to elicit from the mass more accurate knowledge of their features and the effect of remedies upon them. Doubtless something, perhaps much, will be gained by collective investigations; but as the sum is merely the aggregate of all its parts, it is evident that by this method we shall only gain a better quality of simple clinical knowledge. We shall learn important facts in etiology, in distribution and duration of disease, in climatic influence, etc. I repeat that I do not depreciate the indispensable need of making this clinical knowledge as perfect as possible; but can we continue to rest satisfied with it? Is it not imperative that we search deeper into the phenomena of living tissues and try to understand what really goes on within them?

The affirmative answer, which every one is ready to give, may be illustrated by reference to chemistry, which analyzes the intimate character of every known substance, and creates new combinations of them, because it is not content to know only their outward qualities, their form, color, weight, consistence, etc. Chemistry is to a great degree the study of atoms and their behavior. Physics now busies itself with the affinities and repulsions of molecules, and finds in the infinitely small an ample field for its best powers.

In medicine, the aim has for a long time been in this direction. The great implement of search has been the microscope. And if the title of my paper may seem singular, perhaps it will be thought less grotesque if I suggest that the effort to penetrate the mysteries of the human organism is not a little like the attempts of explorers to make their way through a tropical jungle. They may hew ever so sturdily with axe and saw, but the mass of vine and twines, of bush and tree, of grass and leaf, shuts out the light, hampers their labor, and keeps them in deep ignorance of what lies beyond.

When the microscope began its work, how discouraging was the vastness and complexity of the discoveries which it brought to light! How many years has it been diligently used, and how uncertain are we still about many of its revelations! But when a happy conjunction of a man and the proper environment takes place, we may reach better results. Let me give an illustration.

Some thirty years ago Virchow began his studies and lectures upon cellular pathology. The enthusiasm which they awakened spread over the whole medical world. The wonderful attention to detail, and the broad philosophy which signalized his observations, were alike remarkable. His class-room was packed with students from every country, who thought it no hardship to struggle for a seat at eight o'clock in the morning. A man of medium height and slender figure, and with quiet face, you felt the earnestness which burned within him by the tumultuousness and complexity of his sentences, as thoughts crowded thick upon him in a struggle for utterance. With his blackboard behind him and specimens of pathology before him, and microscopes coursing upon railway tracks around the tables which filled the room, he was the embodiment of the teacher and the discoverer. Admired as a teacher, his highest honor was as a discoverer. It was my privilege to see him once more at Copenhagen, and again later, when presiding over a meeting of the Medical Society in Berlin, and to note that much of the wonted energy remains. A nobly gifted man has been placed for more than thirty years in a position where he could command all needful appliances for his scientific work, and what bounteous results have followed! If some of his theories have had to be modified, much that he has done remains—for instance, regarding embolism, thrombosis, and metastasis, we shall be always in his debt. He taught us to regard the cell as the constructive element and essential factor in both normal and abnormal processes of nutrition. The life and importance of the cell, in both health and disease, it has been his work to discover and to teach. The point of view from which he has classified tumors is founded on this basis, and remains the accepted method. The light which he cast upon the nature of inflammations has not yet been obscured, and while other phenomena appear, the multiplication of cells and nuclei, and the formation of connective-tissue in the process of inflammation, will always call to mind the labors of Virchow. The work which he did was within the pathological laboratory of the University of Berlin.

To Professor Cohnheim, and also to one of Virchow's pupils, Professor Recklinghausen, we chiefly owe our knowledge of the phenomena of diapedesis as a part of the inflammatory activity. How incredible it seems that masses of living matter can make their way through the walls of blood-vessels which do not rupture and which have no visible apertures! Professor Recklinghausen is now the director of a nobly furnished pathological institute in Strasburg, whose great museum is almost wholly his own creation.

While Virchow fixed attention upon the forms and activities of cells, their multiplication and degradation, and how they build up tissues both healthy and morbid, we have come now upon a new era in the study of their life and quality. Many observers have striven to unravel the mystery of the cell itself—to bring to light the nature of its contents. The declarations on this subject have been received with a degree of distrust; but now we seem to be approaching a clearer exposition of the matter. The work of the medical pathfinder has taught us that definite and remarkable formations and structure can be seen in cell nuclei when they undergo multiplication. Conspicuously is this set forth by Flemming in his book on "Cell Substance" (Leipsic, 1882); that he has made these discoveries is due to the use of immersion objectives aided by the Abbé illuminator and other similar devices. He speaks with much reserve about tracing organized form in the material of the cell. Although he asserts that in many cases a faint fibrillation can be discerned, he is far less positive about this than some observers. The interesting part of his book is that which describes the multiplication of the nuclei. In a few cases, he says, the division of cell and nucleus is *direct*, by which he means that no visible alteration in their interior structure can be seen while the division occurs. In leucocytes and in amœboid cells is this the fact, and in some other cells of both animals and plants; but in by far the larger number of cells, the division occurs in what he calls the *indirect* way. By this he means that during this act the nucleus elongates, and at each of its extremities appears a complex figure made of filaments, whose arrangement has a great variety of forms. Sometimes it is a mere mesh, sometimes there is a resemblance to a waving fringe of fibres, or they are coiled like a bunch of angle-worms. Innumerable varieties of arrangement appear, and with a certain symmetry of disposition, at the two extremities of the elongated nucleus; or the filaments may cluster around the expanded middle of the nucleus. The plates which he gives in illustration exhibit a wonderful variety. It is not for me to do more than to refer to this subject, I do not venture even to attempt to give a clear account of it. My purpose is served in calling your attention to the opening of another path into the unknown, and that we have come so much nearer to acquaintance with the processes which transpire in the cell itself. To this metamorphosis Flemming gives the name of karyokinesis, and to certain modifications of it he attaches the name of metakinesis. With new phenomena he has been obliged to invent a new nomenclature. He is professor of anatomy in the University of Kiel, and the most of these studies have been made within seven or eight years, in his laboratory.

To another matter with which, both literally and meta-

phorically, the air is full, I must also make allusion. The existence of micro-organisms in countless numbers is no new fact. What influence they exert over living tissues has only lately become the subject of earnest attention. So long as they were not known to have any practical bearing upon human welfare, they interested almost nobody. When, however, it was shown that putrefaction of meat is due to the agency of the bacterium termo, and the decomposition of albumen to bacillus subtilis; when anthrax in cattle and sheep was found to depend on the bacillus anthracis, and that in human beings it caused malignant pustule; when suppuration of wounds was found to be associated with the development of micrococci, and when Pasteur announced that by a process of inoculation cattle could be protected against anthrax, and Lister declared that by carbolic spray and other well-known precautions the suppuration of wounds could be prevented, all the world lent its ear and investigation at once began. To what the germ-theory has developed, it is not within the scope of my remarks to narrate. It is the wonder of the age; nothing has ever arisen in medicine which has had such far-reaching results. We stand expectant, ready not to be surprised at any new announcement of strange and potential discoveries in bacteriology. Whence did all this commotion come? Chiefly from the work-room of an acute and thoughtful man, an experimenter of unrivalled ability, who noted the cloudiness which came over his infusions of meat and studied its meaning under the microscope, and by chemical methods and processes of culture. Nothing could have been more purely scientific than the labors of Pasteur during the years between 1857 and 1863. Happily, his investigations led to results of the utmost value to mankind, and so evident was the connection between study and result, that the world rings with the praises of the man of science.

At the close of the first public dinner of the Congress at Copenhagen, the guests were strolling in the open court of the hotel. Among other dignitaries the Turkish ambassador, in full costume, was present. He sought an introduction to Pasteur, and on being presented, saluted him by kissing his hand, an act of homage which he emphasized by words expressing his profound respect. The world owes a debt to Pasteur like that which it owes to Jenner, and to the discoverers of anæsthesia. For men like Virchow it has scant praise, because it does not understand their work nor their merit. To both alike the reward of honor is due, because each has wrought to the full measure in his own way.

Because labors in bacteriology promise to be fruitful in practical results, the workers in it are innumerable, and we are accumulating a wondrous store of facts. How long is now the list of diseases in which germs make their appearance!—in pneumonia, in endocarditis, in erysipelas, in pyæmia, in tuberculosis, and so on, and so on. One of the most striking illustrations is in the gonococcus of gonorrhœa, whose presence in and around them gives to the pus cells their virulent properties, and, when transferred to the eye, work such lamentable mischief. Without their existence the inoculation of pus in the healthy eye is harmless; pus bearing the gonococci excites the most intense inflammation. Similarly suppurative action in the cornea is often caused by infection by cocci. The proof of causation may be found in the fact that the most effective cure now practised for such suppurations is to sterilize them by the actual cautery. The value of chlorine and of corrosive sublimate was known empirically long ago, but the true reason for their efficacy was not known until the germs were discovered. Now the hot platinum kills at once the organisms which other agents can only less perfectly destroy.

Rosenbach (Wiesbaden, 1884), page 63, says that he knows six distinct microbes which are capable of exciting suppuration in man. Some of them grow without oxygen, others require it. Their activity may be by the production of a poison, such as sepsin or ptomaine, or a putrefactive alkaloid, which is absorbed. The secretions of the lachrymal sac, when it is inflamed, exhibit, according to Sattler, at least three different microbes, which possess pernicious properties to a greater or less degree. Founded upon exact and laborious investigations of germs and their antidotes, is the whole practice of asepsis and antisepsis. As to its importance or its value, it is not necessary for me to speak. But long unfamiliarity with general surgery, and the vivid recollection of the sacredness which was held to belong to the large joints at the time when I was passing my pupilage in the old New York Hospital, under Buck and Watson and Cheeseman and Parker, qualified me to regard with amazement both the operation which Sir Joseph Lister did for a fracture of the patella, and the lack of special interest on the part of the spectators. Freely he laid open the joint, and with much force dragged down the comminuted upper fragment by a stout hook, and wired the pieces together. Meanwhile the carbolic spray was in active operation.

Again, in Heidelberg, I was witness to a still bolder act of surgery, which I may perhaps be allowed to partially describe. Professor Czerny excised the pyloric extremity of the stomach for cancer. The piece removed was not less than one-third of the organ. It measured twelve and one-half centimetres upon the greater curvature, and nine centimetres upon the upper or lesser curvature. The rigid attention to detail in this operation was most noteworthy. The temperature of the theatre was above 80° F.; for two hours previous to the operation the air was charged with carbolic spray, and the apparatus was kept at work during all the proceeding. The assistants and nurses removed their coats and wore long white gowns, many bared their arms to the shoulders, all washed their hands and arms vigorously with soap and brushes, and gave special heed to their nails in the scouring process. Two nurses took charge of the sponges; large porcelain trays, filled with solutions of carbolic acid, held the instruments. Alongside of the operator were two bowls of a weak carbolic solution, in which to rinse his bloody hands and the instruments, and at short intervals this water was changed. Before the cut upon the linea alba was made, the skin was shaved, soaped, scrubbed, and carbolized, and cloths wrung out of a carbolic solution laid close to the wound, and as they became soiled, fresh layers were put over them. The half-dozen spectators were not allowed to approach within ten feet of the patient, because they were not, in the surgical sense, clean. I need not refer to the steps of the operation. It was elaborate and difficult, especially in controlling the blood-vessels and in putting in the sutures to unite the pylorus to the cut end of the stomach. Two hours were consumed. It was the sixth case in which Professor Czerny had operated. He wrote to me, two months later, that the man had made a perfect recovery, and that his temperature had not risen above 100° F. No greater triumph of antiseptic surgery, it seems to me, can be adduced.

Let me briefly refer to what experimental physiology has lately done in acquainting us better with the functions of the several parts of the brain. In this field we can claim some good workers in our own country and in our own academy. But the most painstaking labor and skill, aided by suitable conveniences, have been needed to achieve what has been done. No physician counts these endeavors superfluous—we all wait for further results. I call to mind a room, not less than fifty feet long, the laboratory of the hospital for the insane, in the outskirts of Munich, where Professor Gudden, with three assistants, is carrying on his studies in brain structure, making sections in thin slices of the entire organ under fluid. He was also pushing through the press a book giving the results of his own experiments, and he showed me some of the specimens from animals which he had utilized. A well-appointed establishment and a man suited to the place were there combined. What he did a few years ago, in settling the question of the partial decussation of the

fibres of the optic nerves, will guarantee the thoroughness of his work.

If he be called one of the pathfinders in medicine, you will admit that the *iter a tertio ad quartem ventriculum* is a road not too large for comfortable travelling, and that some difficulties hang about the locality to which it leads.

Let me now call to your notice a man of great ability, who has done valuable work in medicine, but who, by ungenial influences around him, was not permitted to labor in his profession as he might have done, and whose talents have therefore been little appreciated among medical men. Dr. Thomas Young practised in London during the early part of the present century, and was a physician of Middlesex Hospital. In his youth he was precocious, and showed his scientific bent by constructing a microscope from a written description; to do it he learned the principles of optics, and the use of a lathe. At the age of fourteen, he had some proficiency in Greek, Latin, French, Italian, Hebrew, Persian, and Arabic. At nineteen he began his medical studies, and while pursuing them he presented to the Royal Society a paper entitled "Observations on Vision;" he was the next year elected to membership in the society. After taking his degree in medicine he went to Göttingen, in Germany, to continue his studies. The breadth of his aim is quaintly and truly stated in a letter to his mother in which he says, "I by no means wish to confine the cultivation of my mind to what is absolutely necessary for a trading physician." In 1797 he began practice in London. In 1801 he published in the "Philosophical Transactions" the results of further studies upon the eye, in which he anticipated what was more fully set forth fifty years later. He described the existence of astigmatism in his own eye, and proved by immersing it in water that the erroneous curve was not in the cornea but in the crystalline—at least such was his conclusion.

He also calculated the difference between the foc in the vertical and horizontal meridians, and indicated the power of the cylindric glass which would correct it. In 1802 he was made Professor of Natural and Experimental Philosophy at the Royal Institution. Two years later, when he married, he gave up his professorship by the advice of his friends, who considered it likely to interfere with his success in his profession. The comment of Arago upon this act was, that "in England a physician must not addict himself to any kind of scientific or literary research which seems foreign to the art of healing, if he would not lose the confidence of the public." He had, however, written his great paper on the "Interference of Light;" and his after-career was brilliant with researches in physical science and literature. He it was who fully deciphered the tri-lingual inscription on the famous Rosetta stone in the British Museum, and laid the foundation of the science of Egyptian hieroglyphics.

I call this famous man to your memory, not only that one who was little honored may be somewhat better known, but chiefly to bring out the fact that to succeed in medical practice his noble powers must be warped from their natural bent, and his eager mind was driven to investigations in physics, in tables of life insurance, in literary and linguistic studies, because scientific medicine was far inferior to other branches of science, and the prevailing spirit was hostile to efforts in this direction if a physician would gain popular favor. Dr. Young never was popular as a physician, but he happily inherited from an uncle a sufficient fortune. In optics, both physical and physiological, he did achieve great things, but what might he not have done in other fields of medicine, had his environment been more auspicious.

In his time nothing was esteemed in medicine which was not practical, and very narrow was the definition of the word. In this country and in our time we make the same demand with a somewhat broader meaning to the word. We admit that the strictly scientific man is a respectable but rather unintelligible person. How a Wall Street man would stare to hear Agassiz say that "he had no time for making money."

A man lately passed away who was rector of Lincoln College at Oxford, Dr. Mark Pattison. An English reviewer says of him: "A life devoted to learning in a country given over to practice, and in a university consecrated to cram, was original to the verge of eccentricity." "He believed in knowledge as a physician believes in ozone." "His paramount love and faith in knowledge dictated and governed all his mental affinities and sympathies." "He was a true liberal, because he knew what ruin a despotic government could bring upon all independent thought and study. He was no democrat, because he was aware how democracy, in its present stage at least, from no ill-will, perhaps, but out of sheer ignorance, is apt to scorn and destroy a science of which it cannot see the use and meaning."

Like virtue, like beauty, like art, knowledge has no need of apology or of justification. Up to a certain point society will admit this. Our age is more liberal in this regard than its predecessors. The meetings of scientific bodies are reported in the newspapers, and the discovery of comets is chronicled, and Tyndall's lectures are thronged. But do we in medicine hold the purely scientific studies in sufficient esteem? Medicine is, indeed, chiefly an art, but what would the art be, were there no science? As practitioners we, to some degree, separate with the cultivation of specialties. If a new book has more of recent knowledge than a reviewer thinks is easy to take in one meal, he makes the sapient remark that it is not meant for the general practitioner, but for the specialist. Why should not every medical man demand the last results of science in the books which he reads, and who shall assume, like the physician at the table of Sancho Panza, to say that this or that dish is too heavy or too dainty for his digestion? The thing which is to-day the property of the few, will next year be common to all. What men call abstract or transcendental science, will not long remain in the higher regions of study; soon it asserts its affinities with the already known, and in some way touches the ordinary needs of life.

Let me adduce an illustration in the life of one who recently met a heroic death. Edward Henry Palmer was born in Cambridge in 1840. He was not remarkable for talent in his youth, but he showed a curiosity respecting the life and manners of Gypsies, and learned their language by mingling with them. He made a dictionary of Romany for his own convenience, and he learned it with all the vagabond slang. He could always pass as one of the fraternity, and delighted to frequent their camps. After leaving school he became a clerk with a London merchant, and while employed about the docks he picked up Italian, both in its purity and in several dialects, and also French, and bits of other languages from sailors. Chance threw him in the way of a teacher of Arabic, who took kindly to him, and he essayed to learn the language. This and the growing spirit of acquisition of knowledge, moved him to give up business and enter Cambridge University. With comparative ease he gained a fair knowledge of Greek and Latin, but his craving desire was for oriental languages. To these he devoted himself intensely, and especially by intercourse with natives. He cared far less for grammars and dictionaries than for the spoken tongue; but his appetite embraced every modern language, and his facility in them was marvellous. He had a quaint humor, and he would don the dress of a dealer in oriental wares, and with the utmost gravity imitate the bearing and gestures, the protestations and unblushing falsehoods of the most practised merchant in the Turkish bazaars. He travelled in the East, and mastered Turkish, Arabic, Persian, and Hindostanee—not as scholars know them, but as the natives speak the languages—and he knew them in their dialects and variations. He was made Professor of Sanskrit and Oriental Languages at Cambridge. Once a burglary was commit-

ted in the town, and a scrap of paper was found in the room bearing strange characters. The police brought it to him. He told them it was Yeddish, which is Polish Hebrew, and indicated that the thieves were to "crack" another house the next night. They were waylaid and caught. Such was his omnivorous appetite for languages of all kinds. Such a man might never have been known beyond a small circle, and his gifts might not have conferred any great benefit upon mankind, or upon his country, save that he was a bright ornament of its cultured classes. But England found herself at war with Arabi in Egypt, in 1882. The safety of the Suez Canal made the pacification of the desert tribes of the highest importance. Whom to send among them was a difficult question to settle. What man could go knowing their languages, able to command their confidence, possessed of courage and address and discretion? That man was Palmer. The Arabs knew him of old; he had lived among them—they called him Sheikh Abdallah. He won their friendship to England, he secured the safety of the canal. As he was leaving their country his little party were cruelly murdered by robbers bent on plunder, and, at the age of forty-two, a brilliant life was quenched. Would one be likely to think that such a scholar could ever become anything more than a mere wonder and a man apart from his fellows? Such achievements as his are in themselves a triumph, the manifestations of a noble mind, something for pride and gratulation. But when these high talents and attainments found fit scope for play in the enterprise on which he entered, knowing well its peril, we see how indispensable they were to its success, and in the crowning sacrifice of patriotism we bow in homage to the lofty genius of the scholar.

Let me come back to the sphere of medicine, and I will bring before you a man, still living, who has nobly fulfilled the task of combining the highest scientific studies with results which have been of far-reaching utility. In 1850 Professor Helmholz occupied the chair of physiology in Heidelberg. He was a mathematician of rare attainments, he had a special aptitude for physics, he was a close observer and good experimenter. Like Thomas Young, he was attracted to the problems of sight. A question had been raised why the pupil of the eye is always black, save under some exceptional conditions. To this subject he addressed himself.

He not only developed the true explanation of the mysterious fact, but he also contrived the mirror which makes it possible to see the interior of the eye, and he evolved in masterly completeness the whole theory of the ophthalmoscope. Since 1851, improvements in the mechanism of the instrument have been made, but it can scarcely be said that its mathematical theory has been improved. What a boon that has been to the world, directly and indirectly, it is impossible to compute. Pursuing his studies, Professor Helmholz attacked the perplexing question of how the focusing of the eye is effected. To discover it a way must be found to measure the curves of its several refracting surfaces, viz., of the anterior surface of the cornea and of the two surfaces of the crystalline in the living subject. These elements and the distance of these surfaces from each other, and their exact position, must be determined to the fourth decimal. Taking a hint from astronomy, he contrived an instrument which permitted the needed exactness despite the involuntary movements of the most steadfast eye. His ophthalmometer was afterward improved in certain details—his measurements were slightly modified by his pupils working under his directions; but he settled these questions. He pursued the subject of physiological optics until he made a treatise which is the most perfect work on this topic in existence. It is profound and lucid; it is condensed, but it is complete; it demands close study and a mathematical training, but it satisfies the pursuit of the reader. In the ear, and in developing the theory of sound and the mathematics of tones, Helmholz did work scarcely less brilliant. To-day he holds the chair of physics in the University of Berlin, in a laboratory of magnificent equipment. He long since left physiology for his more congenial subject. That he achieved such shining successes in physiology was made possible by his exceptional talents, coupled with his mastery of mathematics and physics. To him the world owes the great strides of the present day in dealing with diseases of the eye, because he gave us the ophthalmoscope.

With this instrument in his hands Graefe began his masterly studies in clinical ophthalmology. The world has never known so brilliant a clinician, and no physician of this century lives again in so many devoted disciples. Under the same stimulus Donders turned from the general subject of physiology to the morbid conditions of refraction and accommodation of the eye, and supplemented the labors of Helmholz by systematizing and elucidating these errors of vision. The correct and scientific employment of spectacles may almost be said to have had its real birth in the labors of Donders.

His laboratory, at Utrecht, is, as you might expect, replete with all that can contribute to his department. To touch upon the labors of those who, by the influence of these men, have enriched the world with knowledge and practical achievements, would occupy the entire evening. I may not even mention any names. I may, however, show how the work of Helmholz in measuring, by an exact yet complicated instrument, the curves of the media of the eye, has borne fruit in the production by Javal, of Paris, of an ophthalmometer which becomes an instrument of daily practical utility. It measures the radius of the cornea with the least possible trouble, and reveals with ample exactness the degree of astigmatism which it may possess. By it what is often a tedious and annoying examination is done in two minutes, and the whole is an objective investigation which does not turn upon the intelligence or visual ability of the patient.

This instrument which is before you, and which was invented some five years ago, is an outgrowth of the studies of Helmholz in 1850.

Why do I present to you facts and illustrations which are more or less familiar to you all? You cannot fail to note that they have been drawn from sources foreign to our own country. You know well how our ambitious young physicians betake themselves to European capitals, and often to obscure small cities, for the knowledge which they crave. I am far from saying or feeling that American physicians are not among the best and most skilful. In surgery especially, and I may instance gynecological surgery, we have commanded the admiration of the world. In these achievements we have excelled mainly by the exceptional talent of certain individuals. Their successes were often a tale of perseverance under crushing obstacles and hindrances, as witness the early labors of Sims. But the advance of scientific study demands proper facilities in addition to the possession of talents. Even men of only average ability can accomplish useful work when they are placed in positions which facilitate it. I do not forget that the discovery of vaccination, of anæsthetics, of the ligation of arteries, was the work of individuals who were not surrounded by elaborate apparatus. But such men as Pasteur and Koch and Helmholz can do their best only when they are placed amid fitting surroundings. Because he did not have them Thomas Young was kept below the height of achievement which he might have reached in medicine. What are the surroundings fitted to bring out the powers of men of this type? They must have leisure and encouragement to work. They must have suitable pecuniary support. They must have apparatus, equipment, and laboratories adapted to the nature of their investigations.

In medicine there are two lines of study and effort. The one deals directly with the sick person, and may be called the bedside study, or, if you please, the clinical study of disease. It is founded largely upon empirical

experience. It is intelligent and rational. It strives to connect symptoms with lesions, and with the use of remedies. It is the practice of medicine which will be wise and sagacious according to how much a physician knows, and according to his consciousness of his ignorance. The second line is that which studies the secretions and tissues by the microscope and by chemical methods; which attempts to study the processes of disease as they may be imitated in the lower animals; which patiently inspects the lifeless body, where alas! only the results, and too often not the sequence, of morbid action are to be found. It attempts to give an accurate account of how remedies produce their effect, and sometimes the laboratory, as in the case of chloral, constructs a new remedy and forecasts what its application must be. The second may, perhaps, be called the philosophical study of disease. Between these two lines there is a wide gulf. How to bring them into closer connection is the problem. My plea to-night is on behalf of the laboratory. That we may have among us the same sense of its need, and the same provision which exists in Europe. Germany has taken the lead; France, Holland, Russia, Sweden, Denmark, Switzerland, and Italy are thus equipped. They do it in virtue of their centralized forms of government and education.

In republican America the case is different. We must act through the general sentiment of the community, and it is our part to awaken in it the conviction that our need in this regard is urgent. In this city we are proud of two recent noble acts of private munificence coming to aid medical teaching, and incidentally medical investigation: we boast the Carnegie laboratory, and the great gift of Mr. Vanderbilt to the College of Physicians and Surgeons. Most timely and most helpful are these generous bestowments. It will not, I hope, be thought invidious if I say that there is a still higher reach for similar philanthropy —above mere teaching, above the training of pupils beginning their course of study, above provisions for communicating what is already known; above these is the need of providing for the teaching of the teachers, of giving scope to well-trained men, already possessed of large attainments, to push their searchings into the unknown, and for study and experiment which shall lay bare new fields of scientific wealth. One such example has already been set in this country in the Johns Hopkins University. Can we in New York not hope for something similar? Will not this Academy set before itself the high ideal of seeking to realize such an establishment? Is it not an aim within its sphere, and fully appropriate to its purposes? Ought we as a profession, and organized in a corporate capacity as the Academy of Medicine —ought we to be content with an inferior aim?

This is not the first time that this suggestion has been brought before you. Most forcibly was it presented by Dr. Barker in his late valedictory address. Without plot or conspiracy between us, my thought has run in the same direction. I have brought before you some illustrations of what the higher medical research has accomplished, and I have referred to the difficulties which beset it.

In our country we have a high degree of average knowledge, we also have men of exceptional talent, who are peers among the highest; but we are just beginning to realize that, to make the most of these men, and to procure for ourselves the benefits which they can bestow, we must give them a suitable equipment, a place to work in, means to work with, and encouragement to pursue their researches into the farthest reaches. A wealthy Californian devotes a fortune to the founding of an unrivalled astronomical observatory. Honor to the man who lays this tribute at the feet of science. Will not men of wealth see that in medicine there is an opportunity and a need for wise liberality, which will not only shed lustre upon themselves and upon our country, but which is certain to bring forth fruit to bless mankind. Here, under the influence, and why not under the auspices, of this Academy of Medicine, why may we not have a laboratory which shall emulate the activities of Berlin and Strasburg, of Kiel and Heidelberg, of Cambridge and Leipzic. It is for us to proclaim our need. We show our zeal by the multitude of isolated observers, who are struggling by individual effort to do this kind of work; but we may justly ask for large and adequate appointments to fitly organize and prosecute scientific medical research. With the abundant wealth of this country, with its self-reliant and ambitious spirit, with its determination to hold a rank inferior to none, with the readiness which has been shown to provide for general education and to encourage certain departments of science, it cannot be long ere the necessity of large endowments for pursuing scientific medical research will be appreciated by those who with intelligence have also wealth.

Great gifts are obtained with little difficulty for hospitals, retreats, and dispensaries, where the wretched and sick may take advantage of medical skill; but the time is yet to come when donors shall see that their charity fails of its full purpose until a portion of it is applied to aiding the medical man to acquire a better knowledge of disease, and how to meet it. No hospital is complete which does not have its scientific appliances and conveniences for the study of the true nature of the diseases which it treats. A larger development of these arrangements is part of the topic to which I have asked your attention, and for which we may justly appeal to the liberality of an intelligent community. Give us endowment, organization, and equipment, and the fit men to utilize them will not be wanting, who shall bring out of them precious fruit, which shall ultimately go into every home with sound knowledge and skilful healing.

QUESTIONS RELATING TO STILL-BIRTHS.[1]

By HENRY DWIGHT CHAPIN, A.M., M.D.,

LECTURER ON DISEASES OF CHILDREN AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, ATTENDING PHYSICIAN TO THE OUT-DOOR DEPARTMENT OF BELLEVUE HOSPITAL.

It is sometimes observed that advancing civilization is particularly hard on women. While the exact truth of this statement can only be verified by an extensive and exhaustive study of statistics, the rapid growth of gynecology, together with the increased difficulty and danger so frequently attending the delivery of children, certainly seem to point toward a tendency to physical degeneracy in women. There appears to be little doubt, likewise, that the number of still-births is somewhat on the increase, although it is very difficult to get accurate and reliable statistics to prove it. The object of this paper is to bring out a few suggestive points of interest in regard to still-births, particularly in reference to causes, statistics, and the peculiarities of the law in connection with still-births and live-births.

It is written with the idea of instituting a discussion, as individual, unwritten experience is largely valuable in forming collective knowledge on a subject of this kind. Whether the Malthusian doctrine in the abstract commends itself or not, it certainly is desirable to save all fœtal life that has begun. Not only has the unborn child legal and moral rights, but the mother is likewise better for giving birth to a healthy, living child. There is no doubt of the fact of a tremendous loss of fœtal life, and that frequently of a quality undesirable to be wasted. As a high state of civilization appears to exhaust women physically, in order to advance them mentally, it is not strange that the more cultured women, who have the means and leisure to correctly train children, are just the ones who cannot or will not have them. The poorer classes, however, crowded in tenement-houses, and unable from their unfortunate environment to bring up children in a healthy condition, either morally or physically, are inordinately prolific.

It is a point of great social interest and importance,

[1] Read before the New York Medico-Legal Society, November 18, 1885.

although beyond the limits of this paper, to consider the immense destruction of fœtal life that is continually going on from natural and criminal abortion, as well as the loss from still-births. In a rapidly growing country like our own, continually reinforced by swarms of immigrants, this question does not assume the immediate importance that attaches to it in some of the older countries of Europe. It is said that in France the Government is becoming seriously alarmed over the decrease in native births, and has offered inducements in the shape of a prize for the seventh child. A still-birth may be defined as the delivery of a dead child in premature labor or at full term. Death may have taken place before, or in consequence of some delay or accident during delivery. Premature labor refers to that occurring after viability and before full term. The following concise definition of viability is found in Abbott's Law Dictionary: "An infant newly born is said to be viable, if the organs are in such a state of regular conformation and development as to render the infant capable of living. But if an infant, newly born, be affected with such a disease or malformation as to render a continuance of life impossible, the infant is said to be non-viable, and, according to some systems of law, is, so far as regards the transmission of right to legal representatives, as if he had never been born." Although there is direct continuity in the life of the fœtus from conception to delivery at full term, a physiological difference exists between a viable and non-viable child. In the former case, not only have the viscera a more perfect development, but the hold upon uterine life is much stronger. A majority of the cases in which the fœtus is passed earlier than full term happen before the period of viability. A miscarriage, by which is meant the expulsion of an ovum, or non-viable child, is a much more frequent accident than premature labor. According to Beck, the ancients believed that the vital principle was not infused into the fœtus until some time after conception had taken place. Thus Galen considered animation to take place on the fortieth day after conception, at the same time that he supposed the fœtus to become organized. We now know that the embryo possesses inherent vitality from the very beginning of conception, but it is not until after viability that this life can exist in any way independent of the intrauterine environment. Works on obstetrics generally state that a fœtus is viable at about the end of the seventh month, or at the completion of the twenty-eighth week of pregnancy. Thus, although a six months' fœtus may breathe feebly after birth, it will usually die in the course of a short time.

There are cases on record, however, in which infants have been born viable at an earlier period than is usually conceded by obstetrical authors. Wharton and Stillé cite a number of such cases. In one instance, a living child was born on the one hundred and seventy-ninth day and lived for four months, when it died of an epidemic disease (*Lancet*, April, 1852). In another case, Dr. Barker, of Dumfries, reported a child born on the one hundred and fifty-eighth day of gestation; it weighed one pound, and measured eleven inches. Three and a half years afterward it was still living, and weighed twenty-nine and a half pounds (*Med. Times*, September and October, 1850). The authors mention another curious instance of survival in a very premature child, narrated by Dr. Rodman, of Paisley. The child's uterine age could not have been more than five months, since, three weeks after birth, it weighed only one pound thirteen ounces, and measured between eleven and thirteen inches. It survived its birth one year and nine months (*Guy's Med. Jour.*). The question of viability is an interesting one, not only as affording a distinction between a miscarriage and a premature labor resulting in still-birth, but also as a subject on which legal distinctions may be drawn. In the case of Marsellis *vs.* Thalhimer (Paige's "Chancery Reports," vol. ii.), it is stated that children born within the first six months after conception are presumed to be incapable of living, and, therefore, cannot take and transmit property by descent unless they actually survive long enough to rebut that presumption. A glance at some statistics derived from the records of the New York City Board of Health will be of interest in the consideration of still-births. It is the desire of the Board that cases of miscarriage be reported as well as still-birth. As it is a misdemeanor to dispose of any body without a burial permit, and as a three months' old fœtus is a body, it follows that all such cases should be reported and a burial certificate given before disposal is made of the fœtus, however small. As a matter of fact, only the smallest fraction of the miscarriages that are constantly occurring are reported, and the remains of the fœtus find refuge in any place from the water-closet to an ash-barrel.

The following table contains the still-births, including such miscarriages as have been reported, and the live-births reported to the Board of Health for the fifteen years from 1870 to 1885. I am indebted to the courtesy of Dr. Nagle, Registrar of Vital Statistics, for the procuring of these figures:

	Still-births.	Live-births.		Still-births.	Live-births.
1870	2,254	14,524	1879	2,191	25,573
1871	2,276	20,821	1880	2,362	27,536
1872	2,322	22,068	1881	2,462	26,130
1873	2,312	22,683	1882	2,658	27,321
1874	2,227	25,747	1883	2,697	28,972
1875	2,274	23,813	1884	2,908	30,527
1876	2,290	23,744			
1877	2,164	25,569		35,639	370,757
1878	2,192	25,729			

According to this table the proportion of still-births, including the miscarriages that have been reported, is to the live-births as 1 to 10.44. This shows an enormously high percentage of still births. An objection may be raised to the reliability of these figures, inasmuch as the returns of live-births are unfortunately defective, owing to the carelessness of physicians and midwives. Death returns are extremely accurate, as burial permits have to be procured, but in the absence of such a necessity birth reports are often allowed to lapse. Physicians should recognize the importance of reporting each case and thus correct this source of error. Still, I doubt if the figures would be very much out of the way if they were taken to represent the total loss of fœtal life at all periods of utero-gestation, in proportion to all the live-births. The immense number of miscarriages that are concealed would more than offset the live-births not reported. The following is the month of utero-gestation in which the 35,639 cases occurred:

1	2	3	4	5	6	7	8	9	10	Not stated.
13	76	497	1,132	2,023	4,052	4,877	5,314	16,902	174	581

It is seen by glancing at this table that a large number of still-births are reported, but comparatively few miscarriages. It is not to be supposed from this that still-births are more frequent than miscarriages. The natural explanation given by the Board of Health is that in the latter cases the fœtus is so small that it can be easily destroyed and disposed of, particularly in cases of criminal abortion and illegitimate parentage. On the contrary, it is much more difficult and risky to get rid of a large and well-developed fœtus without a regular still-birth certificate and burial permit.

There is not the slightest doubt that fœticide is vastly more common in the early than in the later period of utero-gestation. It will never be possible to secure statistics approaching to accuracy on this subject. By adding the number of still-births in the above table, from the seventh to the tenth month inclusive, and comparing them with the whole number of live-births, it is found that in this city, for the past fifteen years, the number of still-births is to the number of live-births reported, in the

proportion of 1 to 13.59. Out of 8,000,000 births, quoted by Tidy from the *British and Foreign Medical Review*, it would appear that from 1 in 18 to 1 in 20 are still-born. Dr. Sozinsky, in the *Medical and Surgical Reporter*, April 4, gives a table from Quetelet, having the proportion of still births in six cities, including London and Paris. Stockholm had the smallest proportion of still-births (1 in 36), while Strasburg had the largest (1 in 11). As regards sex, it is the general experience that a larger percentage of males than females are born dead. Of the 35,639 cases, 20,035 were males, 15,298 were females, and in 306 the sex was not stated. The proportion of males to females is here as 1.30 is to 1, the former being thus not quite one-third in excess, including the comparatively small number of miscarriages reported. This is about the proportion found in other places. A number of causes may be considered as operative in the production of this inequality, such as the fact that there are more births of males than females, and that male infants are often of larger size than females, which increases the time and difficulty of labor. With reference to the period of the year that still-births occur with the greatest frequency, Dr. Sozinsky has published some interesting statistics, based upon the average number of cases occurring in Philadelphia for each month during a period of ten years. According to his figures, May is the month that has the largest number of still-births in proportion to the whole number of births, while in September the still-births are fewer than in any other month, although its whole number of births are larger than in many other months. After September, in which the infant has the best chance of not being still-born, August comes next, and July next in regard to exemption from this accident. From these figures it appears to the author that the fœtus passing most warm months toward the close of uterine life in its mother's womb stands the best chance of getting out safely. He also thinks that the increasing laxity of fibre produced in the pregnant woman by the heat of summer may prove an aid; also that there may be a difference in the size of the child. The factors that contribute to the production of still-births merit a careful attention. Works on obstetrics do not give sufficient consideration to this important subject.

The following are some of the principal causes assigned by the Board of Health, selected and arranged according to their numerical frequency, from reports as far as they have been received: "Difficult or protracted labor; accidents (such as falls, frights, etc.); sickness of mother (uræmia, convulsions, remittent fever, phthisis, malarious diseases, liver diseases, anæmia, asthenia, etc.); funis disarrangements (compression on cord and around the neck, etc.); placental diseases (fatty degeneration, detached placenta, etc.); asphyxia, hemorrhage (flooding); malformation of child (hydrocephalus, spina bifida, etc.); uterine diseases (cancer, metritis, inertia, etc.); atelectasis, constitutional disease of parents (syphilis, scrofula, etc.)." Not a few of the above causes can be avoided by skilful watching and care. Although syphilis is mention last in the above list, it may be reckoned, together with a faulty pelvis as an extremely frequent cause of still-birth. A large proportion of the still-births occurring in this city take place in tenement-houses, in the practice of ignorant midwives. Such accidents occur not only from a lack of proper anatomical and physiological knowledge on their part, but from the too general employment of the ergot of rye to hasten labor. This powerful drug should never be employed in any but careful and experienced hands. It is well known that it produces a tetanic contraction of the uterus, entirely unlike the normal rhythmical action of that organ during parturition. As a result, the infant is soon killed by the constant and unnatural pressure to which it is subjected. Every old woman who goes out to attend a confinement is supplied with her bottle of ergot, which she is not afraid to use. Indeed, some midwives enjoy quite a reputation in tenement-house circles, as possessing medicines that will hasten the pains and get a woman out of her suffering quickly, although it may be at the expense of a badly torn perineum and a still-born child. Some years ago I was called to see a woman in labor on the west side. The head was coming down on the perineum, and the pains, although progressing rather slowly, were still fairly effectual in gradually and safely producing extension. The woman, however, soon lost all patience, and complained bitterly that I was doing nothing to hasten her labor; she said she knew of a midwife in the neighborhood that had medicine to quickly terminate the pains. As her friends sympathized with her feelings, the midwife was sent for, and I retired after refusing to interfere at that stage of the labor. Some time afterward I learned that the woman had died a few days after the confinement, doubtless from a badly detached placenta, and a torn vulva and vagina. What became of the child I never heard. In this case there is no reasonable doubt that, with ordinary care and skill, the labor would have terminated safely and satisfactorily, but the uterus was probably overstimulated by repeated doses of ergot.

I cite this question as a fair example, and doubtless most practising physicians have had a like experience. The midwife question is a very important one in some of the poorer and densely populated districts of this city. A very large number of women are solely dependent upon these persons for help during confinement. It seems only right, therefore, that the practice of midwives should be regulated in some way. A legal sanction or license should be required, and attendance in confinement without such authority be made a punishable offence. I do not think this important question is much helped by institutions intended to give midwives a smattering of obstetrics. No rigid examination need be required, as a large proportion of labors progress safely, and require no great skill on the part of the attendant; if midwives can simply be taught routine treatment, and be able to recognize malpositions, and like emergencies, in time to send for help, the poorer women of the community will be much benefited, and the number of still-births lessened. In this city the still-births among foreign-born parents, who depend largely upon midwives, is more than double the number occurring among native-born people. The most satisfactory way of regulating the subject of midwives is a fair subject of discussion in this Society, and a proper solution of the question will not only lessen the number of still-births, but prevent much malpractice.

The law in relation to still-births and live-births is a subject for consideration. According to Tidy, the law has not defined live-births except by the decision of the judges. He gives the legal definition to be the manifestation of some certain sign or signs of life by the child after it is completely born. This does not imply that the placenta and cord shall have been delivered, but the child itself must be completely external of the mother. The following evidences of life immediately after birth are given: Muscular twitchings, respiration, crying, pulsation in cord, and beating of the heart. A case is cited in which mere muscular twitching, independently of breathing and other vital phenomena, was decided in the affirmative to constitute a sign of life in a case of disputed still-birth. There should be more of a correlation between law and physiology in this matter. According to the law, as stated above, an immature fœtus of five months, in no sense viable, may, by a few muscular twitchings immediately after birth, show an ephemeral spark of life, but, according to legal tests, approved by decisions of judges, be considered a live-birth. Supposing, on the other hand, a child at full term, whose head and shoulders have been born, cries lustily and shows other undoubted signs of vigorous life, yet, if by accident or design, death takes place before the feet have left the vulval ring, it is legally not a live-birth, but a still-birth, with all the consequences that the latter may entail. It

is obvious that there must be some legal distinction between still-births and live-births.

Much legal as well as physiological confusion would be prevented if some factor allowing of individual life, independent of the mother, should be taken as a test of live-birth. The immediate environment, whether it be the vagina of the mother or the lap of an old woman, may be considered non-essential so long as the infant has been sufficiently extruded to begin the physiological processes that will allow of a separate and independent life. Respiration, which results in an independent oxygenation of the tissues of the child, should be the only legal test of live-birth, as, without this function being performed, existence apart from the mother is impossible. Beating of the heart alone should not be considered a test of live-birth, as this takes place "in utero," and soon stops after birth when the circulation through the umbilical cord is checked. Leishman states that the lungs enter upon their function immediately upon the birth of the child, and when anything occurs to prevent the speedy occurrence of the respiratory act, the child is still-born. When the seat of respiration changes from the placenta to the lungs, independent life begins. After birth, if the heart beats but the child does not breathe, it is still depending upon that intrauterine lung. the placenta, for oxygenization, and hence is living under the same conditions as before leaving the womb. The child is alive, but in the same sense as it was alive before birth, and if death takes place without respiration, it should be considered still-born. It is stated in Beck's "Jurisprudence" that when a child is born alive, but has not yet respired, its condition is precisely like that of the fœtus "in utero." It lives merely because the fœtal circulation is still going on, as none of the other organs undergo any change. The lungs remain as they are in the fœtus, and the organs circulating the blood are in the same state. In Germany (Wharton and Stillé) a distinct vocal sound is required by law as the evidence of life. This appears, however, to be modified in practice by the substitution of breathing for vocal sound, and the doctrine is accepted that respiration and life are reciprocally evidences of one another. The Scottish law (Abercrombie) requires that a child must have cried after its entire birth before it is considered to have been born alive. A few apparently authentic cases are on record in which slight respiration has taken place before birth, with the head at the superior strait or in the vagina. It may fairly be considered doubtful whether the feeble sounds heard in a few cases have really been produced by the fœtus; but still, to avoid legal complication, respiration after the child has *begun* to be born should be considered the test of live-birth. As the law now stands, a child may breathe freely when it is two-thirds delivered, and yet not be accounted born until fully expelled from the mother.

The disputes in relation to still-births and live-births have arisen principally in connection with infanticide, and the law known as tenancy by courtesy. By the latter it is understood that when a married woman dies without children her property passes to her heirs-at-law, unless she shall have given birth to a living child during her married life; in which case her husband becomes a tenant by courtesy for life of her estate. Washburn on "Real Property" (vol. i.) states that in most of the States where courtesy is allowed, great strictness is required in the proof that the child was actually born alive in the lifetime of the mother. In the case of Marsellis *vs.* Thalhimer (Paige's "Chancery Reports," vol. ii.), it is stated that the party who claims property through the child is bound to establish the fact that it was born alive; and if the child never breathed there is no legal presumption in favor of the fact. The peculiarities of the law in regard to live-births are most markedly seen in connection with infanticide. To convict of this crime it is necessary to show that the infant was killed after birth of the whole body, even if it breathed and cried before complete extrusion. Tidy well states that to require the body of a child to be entirely external to the body of the mother before being considered legally born, is a physiological absurdity, and a direct encouragement to child-murder. He cites an instance in which there was actually drawn a distinction between physiological life and legal life, Erle, E. J. (R. *vs.* Christopher, Dorset Lent Assizes, 1845). As a result of this distinction, a man who had cut off the head of a child while it was being born was acquitted of infanticide. Again, if a child that has been born, but does not breathe, exhibits a slight beating of the heart, and is then destroyed, the perpetrator is guilty of child-murder, although continued existence may have been impossible. Wharton and Stillé state that while it is not enough for the child to have breathed, unless the whole body was brought into the world, and while more than one learned judge has expressly ruled there must be an entirely independent circulation; on the other hand, fifteen judges have united in holding that to constitute such an independent existence, so as to constitute murder, it is not necessary that the child should have breathed, nor that the umbilical cord should be severed. It would save possible injustice, as well as confusion, if, in the distinction between still-birth and live-birth, respiration be adjudged to be legally the essential condition of life.

29 West Forty-Second Street.

HYPERTROPHY OF RIGHT HEART, WITH DILATATION—ITS RELATIONS TO ABORTION AND DEATH.

By A. G. BROWNING, M.D.,
MAYSVILLE, KY.

Cases like the following, while not exactly rare, possibly are enough so to arrest attention. Without reference to frequency, the teachings seem to me of practical value.

October 15th.—Was called by Dr. J.T. Strode, of Maysville, in consultation. Case: Mrs. S——, aged thirty, rather frail, thin, and anæmic; nervous temperament; four months advanced in first pregnancy. Though long subject to nervous vibrations, had enjoyed fair health up to a year ago, when she had a prolonged attack of malarial fever, since which and her subsequent pregnancy she had sharp turns of palpitation and dyspnœa upon slight exertion. It was for a pronounced attack of this kind that Dr. S. was called, and there being that in the condition which, giving merely functional possibilities due weight, led him to believe in structural lesion, and to thoroughly explore in consultation.

The resulting diagnosis was, hypertrophy of right heart, with dilatation. The distinctive features of this condition were well marked: area of cardiac dulness largely increased transversely; apex beat in sixth interspace; feeble and intermittent heart-beat; epigastric pulsation and disordered rhythm. The ultimate and more grave results of all this were becoming manifest in the deranged pulmonary circulation, as shown by dyspnœa, cyanosis, and commencing œdema. The situation compelled a discouraging prognosis, and reduced treatment to the merely palliative. Digitalis, quiet, nourishment, and fresh air was the prescription.

October 16th.—Patient a little more comfortable; the digitalis had steadied the heart-action somewhat, and there was an expression of more general ease—that was all. Digitalis, a little wine, and nourishment.

October 17th.—9 A.M.: Condition essentially the same—a shade more œdema; some puerile respiration over anterior chest-wall, with corresponding dulness and mucous râles posteriorly; dyspnœa and cyanosis much the same. Some unrest, but mind clear; temperature normal, strength fair; no other change perceptible—certainly nothing indicative of abortion, for which an eye was kept. Urine now taken for examination, but owing to early subsequent events was not tested, and the material finally misplaced, which, in view of all points involved, is to be regretted. Digitalis, with appropriate nourishment and absolute rest.

Were hastily recalled at 11, A.M. Patient had aborted; the whole time from initial pain not exceeding forty minutes. The placenta remained, but came away readily. Hemorrhage free, only in view of the condition, the fluid being dark and non-coagulable. The uterus was somewhat flaccid even under ergot, and some wasting continued for a time. The prostration was now extreme, and so continued at 9 P.M., the time of our last visit, notwithstanding external warmth and general stimulation. At 2 o'clock next morning, fourteen hours after aborting, she asked to be turned in bed, and in the movement died without a struggle.

As I see it, here we have the condition precedent—the heart trouble; as the incident, the death of fœtus and expulsion; as the resultant, hemorrhage, which, in the condition, necessarily meant death to the patient.

Confessedly this was an extreme case—so near the border-line that both the rational and physical signs might suggest a question whether or not the heart-trouble had culminated, resolving all that followed into mere mortuary phenomena? Nay, that the collapse, from whatever cause, might have been followed by like results? But there was that in the general and special condition, which, minus the determining factor—hemorrhage—forbade the idea of immediate dissolution; plus the same, death was a logical and necessary sequence. Even though the patient were *moribund*, abortions with hemorrhage have been known to occur in the asphyxia—the agony of death—as in coma from cerebral apoplexy, where the presumption was strong that no other cause than that of toxæmia was at work (Barnes). But it is fair to assume, in view of the conditions actually present in this case, that the uterus was responsive, through natural channels, to excitation, and was yet capable of physiological action; that the modus was dynamic rather than static.

And if so, I may present this case in illustration of the theory that heart-disease, through the toxæmia of carbonic acid, becomes a centric cause of fœtal death and consequent abortion. And with the hope, too, if accepted as typical, of erecting a landmark in practice, visible and intelligible to those who may be so unfortunate as to encounter like conditions.

In relation to the premises, views have changed somewhat, or advanced, since the time of Sir Charles Bell, who taught that among the maternal causes of abortion anæmia was frequent, and this through deficient blood-supply to the spinal cord. Brown-Séquard, however, demonstrates that the respiratory movements are not so efficient in the anæmic condition, hence the accumulation of carbonic acid, hence toxæmia, hence spinal excitation and the resulting abortion. Barnes accepts the reasoning, and assigns some forms of organic heart-disease as an active factor in the production of abortion, explained by the action of carbonic acid thus produced upon the uterine fibre, "or through the direct irritation of the diastaltic centre, and partly through the extravasating property acquired by the blood." While the heart-lesion in this case is not specified as a causative in abortion, dilatation of the right heart is, *per se*, the condition in a line with the theory. The engorged fœtal circulation, enlarged liver, congested kidneys constipated bowels are all tributary to the pulmonary stasis producing the tormenting cough, difficult respiration, serous effusion, and fatal cyanosis.

There is no more fruitful and unerring source in the organism for the alleged toxic agent carbonic acid.

It is not pertinent here to investigate the origin and trace the development of the heart-trouble. Theory and teaching would indicate that some obscure valvular lesion, as in other cases, was at bottom of it. And if it be correct that hypertrophy is a conservative process, the disturbed compensation likely occurred during the attack of fever, since which real trouble—synonymous in this case with dilatation—began.

The *rationale* of the movements seems to me clear: the abortion, hemorrhage, and death were logical sequences of toxæmia from carbonic acid, and this induced by hypertrophy with dilatation of right heart, the hemorrhage being the determining factor in the cardiac struggle. I should expect every unfortunate, under such circumstances, to die, and it is something to be able to say so in advance. While familiar with the theory in the premises, I would have been obliged to some one for details of a case in practice. Hence this, with a well-meant purpose.

Clinical Department.

A CASE OF BRANCHIAL CYST.

Dr. C. E. Busey, of Lynchburg, Va., gives the following report of one of these rare cases:

"In presenting this rare case of congenital tumor of the neck, I will only give its history and treatment, and refer the readers to Dr. Henry Dwight Chapin's excellent article, published in The Medical Record, July 25, 1885, giving the history, treatment, and embryology of two cases. A five-year-old boy was brought to me by his father to consult about a diffused fluctuating swelling, situated under his right lower jaw, which had been growing for six months, and when first noticed by his mother it was the size of an almond. As the little fellow had always been perfectly healthy, and had never complained, his parents paid no attention to the enlargement until it reached its present size. Becoming alarmed, they brought him to me for treatment. Upon examination, I found a growth about the size of an egg situated under the right lower jaw. Free manipulation produced no pain or discomfort. Skin, mouth, and teeth were found to be in good condition. No history of an injury. Family history good. Suspecting a congenital cyst, I introduced a hypodermic needle, and withdrew a straw-colored fluid, which, upon microscopic examination, was found to contain epithelial cells, confirming my suspicions. The introducing of the needle and withdrawal of fluid set up an active inflammation, which caused the tumor to decrease and disappear."

Progress of Medical Science.

Dangers of Antithermic Remedies.—In a recent therapeutical conference Dr. Dujardin-Beaumetz discusses resorcine, kairine, thalline, and antipyrine, and advises caution in the use of the first three agents especially, from their active toxic effects. After referring to the eminently antiputrefying and antifermentative properties of resorcine, he states that he had used it in pyrexia without obvious effects, probably on account of the smallness of the dose. He finally abandoned it altogether in the treatment of rheumatism and typhoid fever, not so much on account of its want of power as because he observed toxic symptoms. Resorcine is not only an irritant, it is also a toxic agent; and in his experiments upon dogs it was determined that a dose of two and one-half grains per pound of weight of the animal produced convulsive phenomena, and death was caused when the proportionate dose was increased to eight grains. After death, visceral congestions were discovered, and especially very intense pulmonary engorgement, as in animals poisoned by carbolic acid. Man is even more susceptible to the effects of resorcine than dogs. Munel reports a case in which a single dose of fifty-three grains rapidly induced a condition of great gravity, which, however, was finally overcome. Dr. Beaumetz says: "While recognizing resorcine as less toxic than phenic acid, I conclude that it is a dangerous antithermic agent, for I found in my typhoid patients treated with resorcine the same depression of fevers, the same adynamia, the same pulmonary congestion, which I had found in those to whom I had administered phenic acid. I

have therefore abandoned this medication, and I believe that, even in Germany, resorcine is not much employed internally, but it remains, on the contrary, a very valuable remedy for external use in the treatment of unhealthy wounds." Kairine is an antithermic, acting by diminishing the respiratory power of the blood and destroying hæmoglobin. The recent researches of Brouardel and Paul Loye confirm this view, and show that thalline and kairine exert the same destructive effect upon hæmoglobin. Moreover, contrary to the usual action of antithermic agents, kairine and thalline have no influence whatever upon fermentations. "Kairine should therefore be rejected from therapeutics; it is a dangerous drug, since it only produces antithermic effects by destroying the hæmoglobin and profoundly altering the blood, circumstances which should be avoided in the infectious febrile diseases." Antipyrine is less toxic than either resorcine or carbolic acid. While it takes eight grains of resorcine per pound to kill a rabbit, it takes thirteen grains of antipyrine. The toxic effect, moreover, is almost the same; it produces tetanic and paralytic symptoms analogous to those caused by strychnine-poisoning. It cannot be doubted, therefore, that antipyrine acts upon the cerebro-spinal axis, and it is probable that it lowers the temperature by modifying the nervous heat-centres. Contrary to kairine, antipyrine does not appear to change the liquor sanguinis, and particularly the hæmoglobin. It has also hæmostatic properties which Henoch declares superior to those of ergotine and of chloride of iron. (This is worth bearing in mind in treating hæmoptysis.) Antipyrine diminishes the urinary secretion, but increases the action of the glands of the skin, which renders it inconvenient to use in cases of tuberculosis. Like the phenols and oxyphenols, antipyrine is an antiferment. The study of recent antithermics shows that the effects of these new agents vary with the nature of the fever: a temperature of 104° in a phthisical patient will be lowered by eight grains of antipyrine, while in a typhoid case it might be without effect.—*Philadelphia Medical Times*, October 3, 1885.

Vesical Irritation of Reflex Origin.—Dr. Emil Schlegel reports in the *Algemeine Medicinische Central Zeitung*, of October 3, 1885, the case of a man, fifty-one years old, who had suffered for years from an extremely irritable bladder, for the relief of which he had tried many remedies without avail. The urine showed nothing abnormal, and for a long time the case baffled the skill of several physicians. Finally the writer discovered accidentally that the prepuce was rather tight, and that beneath it was an old accumulation of smegma. This was removed, and in a very short time the patient was relieved completely of his distress.

"Ideal" Cholecystotomy.—In the *Weekly Medical Review*, October 31, 1885, Dr. A. C. Bernays, of St. Louis, reports a successful case of cholecystotomy, upon which he bestows the epithet "ideal," for various reasons sufficient unto himself. The case was one of cholelithiasis, with impaction of a calculus in the cystic duct. The gall-bladder was first tapped, then incised, and after cleansing with ordinary water was stitched by seven ordinary silk sutures and eight Lembert sutures. The latter were intended to embrace only the peritoneum, and perhaps some fibres of the muscular coat. They were applied in such a manner as to completely cover the simple interrupted sutures. No "antiseptic tricks" were called into requisition. The patient made a rapid and complete recovery. From a critical study of this case, and similar ones scattered through the literature of the subject, the author is led to formulate the following conclusions: 1. The causes which indicate an operative interference with the system of gall-vessels are: *a*, jaundice; *b*, paroxysmal pain, or a tumor in the right hypochondriac region; *c*, suppuration; *d*, peritonitis; these conditions to be either severally or singly recognizable, the presumable origin being biliary calculi; *e*, malignant disease. 2. Explorative laparotomy must be preferred to acupuncture or aspiration as a diagnostic measure. 3. The incision in the linea alba is preferable when there is much doubt regarding the seat of obstruction, because the larger ducts can be reached much better from this incision than from the incision parallel to the free border of the ribs. 4. The escape of bile through an abdominal fistula is not injurious to the process of normal digestion. The bile is an excretion, and probably of no more use in the intestinal canal than the urine in the bladder. 5. Jaundice, when caused by an obstruction of the common duct, is no contraindication to natural cholecystotomy. We may often save life by its early performance. 6. Cholecystotomy, natural and ideal, and cholecystectomy, are the three operations at our service; cholecystenterostomy may be useful, but it has not yet earned a place among approved surgical procedures. 7. Ideal cholecystotomy is indicated when the bladder is normal in structure and when the gall-ducts have been cleared of obstructing calculi. 8. Natural cholecystotomy is indicated when the bladder is ulcerated or suppurating, or when there are permanent obstructions beyond reach at the time of operation. 9. Cholecystectomy should be limited to cases of otherwise incurable or malignant disease of the gall-bladder.

Gonorrhœal Urethritis in Children.—In the *Jahrbuch für Kinderheilkunde*, Dr. Widmarth describes two cases of gonorrhœa occurring in little girls. The first case was that of a little girl two years of age, who suffered for a long time with purulent conjunctivitis and also with a discharge from the vagina. Microscopical investigation revealed gonococci in both secretions. The child's mother had given birth to an infant six months previously, which manifested a severe conjunctivitis on the third day after birth. The mother herself suffered with suppurative adenitis in both groins two months after her confinement, and somewhat later with a sensitive tumor attached to the uterus. The secretion from her urethra contained gonococci. The father had had gonorrhœa. The second case concerned a girl, aged twenty months, who had long suffered with a purulent discharge from the genitals. The urethral secretion contained gonococci in abundance, and there had been a purulent conjunctivitis soon after birth. The mother's urethral secretion contained gonococci, and the father knew that he had previously suffered from gonorrhœa. It was not possible to say, in these two cases, exactly how the contagion had been communicated. The author thinks it may have been due to the use of the same sponges for washing by both mother and child. Sonden has reported two cases of vulvo-vaginitis in children of six and five years. In both cases gonococci were found in the secretions. The origin in the first case could not be ascertained; in the second it was found that the mother, who was pregnant at the time of examination, had suffered for a long time with a purulent discharge from the genitals. The father was not examined. The author also found gonococci in the urethral secretion of a boy eight years of age, and also in that of the boy's sister, who was nine years of age.

The Treatment of Diseases of the Lungs by Pneumatic Differentiation.—The pneumatic cabinet appears to be finding favor with the profession, as applicable to the treatment of pulmonary disease. In the *Journal of the American Medical Association*, November 7, 1885, Dr. A. S. Houghton, of Chicago, records his experience with this method in a series of thirty-four cases. He concludes from the study of these cases that: 1. Pneumatic differentiation is of undoubted service in all conditions of primary infiltration. 2. Where the febrile movement has been unchecked for many weeks before treatment, improvement, if any, will show itself within the first ten or twelve applications; if there is no abatement of symptoms its continuance is of questionable utility, and it may be absolutely contraindicated. 3.

That phthisical disease at the apices is more favorably treated than when at the base of the lungs. 4. That it is possible by this means to more thoroughly medicate the lungs than by any other known method. 5. That the expansion of the lungs by differentiation is itself a therapeutic measure of great merit. 6. That peri- and inter-vesicular exudation is capable of cure by this method, and even third-stage phthisis is benefited, at least temporarily. When the febrile movement is excessive, or when the evidences of septicæmia are pronounced, it is not wise to use the pneumatic cabinet.

Wound of the Gravid Uterus, with Reproduction of the Amniotic Fluid.—At the Italian Congress in Perugia Dr. Chiara related a case of a woman, thirty-four years of age, who had a large abdominal tumor. It had been noticed for about four months, and was bilobular. The left lobe was of the size of an orange, and fluctuating; the right was less distinctly fluctuating, and extended as high as the hypochondrium, being apparently inseparable from the uterus, the neck of which was small. There was complete amenorrhœa. Pregnancy was at first suspected, but this diagnosis was afterward rejected. A trochar was introduced into the left lobe, and about thirteen ounces of a slightly albuminous fluid was withdrawn. A second puncture gave exit to a reddish gelatinous fluid. A diagnosis of cystic sarcoma was then made, and an operation was decided upon. Laparotomy was performed, and, one lobe being punctured, a fœtal head was discovered. The other lobe, the real tumor, having chocolate-colored contents, was then removed, and the wound of the uterus was closed with sutures. Labor took place later, and presented nothing abnormal; and although recovery was slow, it is now complete.—*Journal d'Accouchements*, October 30, 1885.

Fracture of the Ribs from Muscular Action.—At a recent meeting of the Hospitals Medical Society of Paris, M. Desnos reported two instances of this rare accident (*La France Médicale*, October 20, 1885). The first case was that of a man, thirty years of age, who suddenly felt something snap on the left side of the chest during a violent fit of coughing. Examination showed fracture of a rib. The man had received no injury, and no other explanation for the occurrence of the fracture could be found than muscular action. The second case was very similar to the first, the rib being fractured during an attack of coughing. This patient was sixty years old. Although both these cases occurred in male subjects, the accident is more common in females. That sneezing is not always a harmless act is illustrated by the following case, reported by Dr. Hal C. Wyman in the *Journal of the American Medical Association*, November 7, 1885. "Mr. M——, aged 72 years, remarkably vigorous and healthy for his years, summoned me hastily for relief of severe pain in his right side, which had commenced suddenly after sneezing with unusual force. I found him standing, supported by a chair, his face pale, his breathing difficult and provoking cries, with pain in the lower part of the right side. I suspected pleuritis and neuralgia, and was surprised on placing my ear on his chest to hear distinctly the crepitus peculiar to fracture of bone. Further examination showed a fracture of the eighth rib near its angle. The treatment consisted in placing three strips, fourteen inches in length, of Seabury & Johnson's rubber adhesive plaster obliquely over the right side, crossing the ribs at right angles. The plasters were adjusted with sufficient firmness to draw the ribs snugly together, and to limit the motion of the fractured one. Recovery was prompt, and without complication. This case is of interest because it was unquestionably caused by sneezing, and the fact that sneezing is not usually referred to as a cause of fracture of the ribs. A glance at the mechanics of sneezing will show that two powerful sets of muscles may be brought into antagonism in a way to expend their opposed forces upon the ribs, making the fracture simply a mechanical matter. The treatment by means of plasters having some permanency of adhesive power has proven in many cases of fractured ribs, as it did in this one, a great advantage over the old method of a broad bandage encircling the chest. It permits freedom of motion on the uninjured side of the chest, while it insures sufficient immobilization of the fractured bone to control pain and favor union. It is said that insane persons are particularly prone to fracture of the ribs, and that sneezing among them is not infrequently the cause."

Treatment of Umbilical Hernia.—The following simple method is recommended by Dr. Archambault (*Journal d'Accouchements*, October 30, 1885). A piece of white wax is rolled between the fingers into a little ball the size of a marble. It is then cut in two, and one of the halves placed, with its convex side down, into the umbilical depression, and retained there by a strip of adhesive plaster. In an hour or two the little hemisphere becomes sufficiently softened to adhere to the skin, and thus answers as a truss, without any other support.

Antiseptic Treatment of Croup.—The following is a plan of treatment recommended by M. Renon (*Journal de Médecine de Paris*, October 18, 1885). The patient is placed in a well-ventilated room of medium size, the temperature of which is maintained at from 68° to 75° F. Upon an oil-stove is kept a vessel, of a capacity of two quarts, in which the water is constantly boiling. Into this is put, every three hours, a tablespoonful of a mixture of salicylic acid, 56 parts; benzoic acid, 112 parts; carbolic acid, 280 parts, and alcohol, 468 parts. The stove is placed near the bed, and the steam impregnated with this mixture is conducted, by means of suitably arranged curtains, to the patient. The patient is kept in this atmosphere until the symptoms have entirely disappeared, and for two or three days after; and, if tracheotomy has been performed, until the wound is closed. A close watch should be maintained over the case, and if any symptoms of poisoning are manifested, the quantity of carbolic acid should be diminished.

Hypertrophy of the Male Breast in Pulmonary Phthisis.—At the meeting of the French Association for the Advancement of Science, at Grenoble, M. Lendet read a paper upon certain changes in the mammary glands of men suffering from pulmonary tuberculosis. The glands themselves are not tuberculous, but they become swollen, and present as tumors, having a diameter of from one to two inches. The skin covering the breast is unchanged in color, and the subjacent connective-tissue preserves its normal character. The gland is the seat of severe pain, which radiates over the entire chest-wall. The breast upon the side where the tubercular lesion is most marked is the one more especially involved, though not infrequently both glands are enlarged. The condition is one of congestion, and is never accompanied with lymphatic enlargement. It usually exists for several months, and terminates in slow resolution without suppuration.

Repeated Attacks of Erysipelas.—M. Verneuil read a paper on this subject at a meeting of the Surgical Society of Paris (*Journal de Médecine de Paris*, October 25, 1885). Regarding the cause of repeated attacks of erysipelas occurring in the same individual, he said that it was easy enough of explanation when there was contact with other cases of the same disease, but in an instance like the following the cause was less easily discoverable. A Sister of Charity had had twelve attacks of erysipelas in eight years, the disease returning without any apparent cause, as the Sister had had nothing to do with others suffering from the same affection. On examining the patient, M. Verneuil found a number of eczematous scales on the scalp, and some little cracks in the skin between the pavilion of the ear and the head. He thought that in this case the microbes of erysipelas inhabited the scalp and found admittance from time to

time as new cracks formed behind the ear. He related also other cases of a similar nature, from a study of which he had come to the conclusion that the erysipelatous germs may exist for an indefinite period on certain portions of the body, and then the disease manifests itself anew upon the appearance of the slightest abrasion. He advised a thorough disinfection of the whole body in every individual who had suffered from an attack of erysipelas in order to prevent relapses. In contrast with these views, however, are those expressed by Dr. Labastide in an article on perversion of nutrition published in *L'Abeille Médicale* of October 26, 1885. He relates the case of a lady, fifty-seven years of age, who had suffered for many years from repeated attacks of erysipelas, recurring at very short intervals and excited by the slightest causes. The patient had tried various modes of treatment for years, but always without success; and her existence was one of misery, for she never knew, on going to bed, whether she would awake with a red face or one of natural color. It was noticed, however, that emesis and purgation shortened the attacks somewhat, and it was also ascertained that the patient suffered much from acid eructations. It was conjectured that the repeated attacks of erysipelas were dependent upon disordered digestion and malassimilation, and as a corrective of this condition pancreatine was ordered. During the five months which had elapsed since this treatment was begun there had been no erysipelatous attack, and the patient had improved in every way. The result of treatment in this case led the writer to believe that the cutaneous affection was directly dependent upon a perversion of nutrition.

Hemorrhagic Pleurisy.—M. Sorel reports several cases of this disease, having in their origin a common factor, viz., a state of malnutrition consequent upon want, overwork, alcoholism, or a pre existing disease. The dyscrasia so produced was the predisposing cause of the hemorrhage, which was caused directly by the rupture of the fragile vessels in the newly formed membranes. There was no pathognomonic sign of this condition, and its presence was determined only by puncture. The gravity of the prognosis results rather from the state of the general nutrition than from the hemorrhagic nature of the effusion. As regards the therapeutic management of such cases, the prime indication is to promote, as far as possible, good nutrition, and thus remove the causal conditions.—*L'Union Médicale*, October 15, 1885.

Discoloration of the Skin following the Use of Arsenic.—In a number of children who had been taking arsenic for various troubles, during a period of four or five months, Dr. Guaita observed a bronze hue of the skin, recalling that of Addison's disease. This discoloration began on the neck, and extended thence to other parts of the body; it was less marked on the face, legs, and back than on the abdomen, chest, and upper extremities. The arsenical preparation employed was Fowler's solution. The coloration of the skin usually showed itself during the fifth month of the use of the drug, and sometimes first appeared several days after the remedy had been discontinued, and disappeared after desquamation in about four weeks. All the patients were children of people in easy circumstances, and were from two to ten years of age.—*Annales de la Société Médico-Chirurgicale de Liége*, No. 9, 1885.

The Seat and Force of the Cardiac Pulsations.—Drs. De Renzi and Reale have been studying for some time past the differences in location and force of the cardiac pulsations in various diseases of the heart and great vessels. The conclusions arrived at by them from the study of a large number of observations, and published in the *Rivista Clinica e Terapeutica*, No. 9, 1885, are as follows: 1. In *pericarditis* the heart beat is usually strong and is seen to the left of the median. 2. In *mitral insufficiency* it is weak, and found in the fifth intercostal space, or, in exceptional instances, in the sixth; in about one-half the cases it is to the right of the mammary line, and in the other half, on the line to the left of it. 3. In *mitral stenosis* the pulsations are usually strong and accentuated, and are almost always located in the fifth intercostal space and to the right of the mammary line; very rarely they are seen in the sixth space or to the left of the line. 4. In *aortic insufficiency* they are strong and often expansive; most frequently they are found in the sixth intercostal space, less often in the fifth, and very rarely in the seventh, and almost without exception to the left of the mammary line. 5. In *aortic stenosis* the heart-beat is feeble, and situated, as a rule, in the fifth space to the left of the mammary line. 6. In one case of congenital *pulmonary stenosis* the beat was of moderate intensity, situated in the fourth intercostal space, between the parasternal and mammary lines. 7. In *aneurism of the thoracic aorta*, the cardiac pulsations were found nearly always in the fifth space, and to the left of their normal seat. 8. In comparing the different pulsations, it was found that they were pushed to the left in relative hypertrophy of the right ventricle, and downward in eccentric hypertrophy of the left ventricle; they were strong in eccentric hypertrophy of the right ventricle, and weak in simple or concentric hypertrophy.

Bronchial Urticaria.—Dr. Ruelle reports the following case in *Le Concours Médical* of October 17, 1885. A boy, aged fifteen, was attacked suddenly with a generalized eruption of urticaria, accompanied by fever, œdema of the face, and headache. In the evening his breathing became so oppressed that the writer was sent for in great haste. On his arrival he found the patient suffering from dyspnœa with whistling respiration, but there were no symptoms implicating the lungs; the cutaneous eruption had disappeared. In about half an hour the dyspnœa subsided, and then the eruption on the skin returned. The following day the same alternation of symptoms occurred, and then the trouble ceased. The author believes that the dyspnœa was due to an urticarial involvement of the bronchial mucous membrane.

The Danger of Phenic Acid Injections in Typhoid Fever.—Dr. Villebrun reports several cases of very grave toxic symptoms occurring in children after the administration of carbolic acid in enema. In one case, that of a child aged six, less than seven and a half grains was given; and in another, aged eight, not much over three grains. Both these children showed very marked symptoms of poisoning, profuse sweating, coldness of the extremities, and loss of consciousness, and reaction took place only after several hours. This hardly bears out the statement made by M. Desplats before the Paris Academy of Medicine, in 1880, that from fifteen to thirty grains of phenic acid could safely be given in rectal injection. In another instance the author ordered for a patient, aged sixteen, seven and a half grains in six ounces of water, a teaspoonful to be taken internally every hour; but after the third dose toxic symptoms declared themselves, and the administration of the remedy had to be suspended.—*Le Concours Médical*, October 17, 1885.

Prostatic Calculi.—At a recent meeting of the Surgical Society of Paris, M. Reclus reported the following case (*Revue Médicale*, October 24, 1885). A patient who had just had an attack of renal colic passed fourteen small stones by the urethra. Upon the introduction of a sound an obstruction was found at the level of the prostate, and as the instrument passed there was a sensation as if it were going over a number of roughened bodies. There was no stone in the bladder. Rectal examination revealed the presence of a hard swelling in the prostatic region. A perineal incision was then made on a guide, and 32 calculi, weighing 730 grains, were extracted; two of these were adherent, and were removed with difficulty.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, November 28, 1885.

THE PENALTY FOR REPORTING CONTAGIOUS DISEASES.

THE protest on the part of the medical profession here and elsewhere against the verdict of the jury in the case of the Drs. Purdy, of this city, who were fined for reporting a case of suspected contagious disease to the Health Board is significant in its purpose and far reaching in its influences. The questions involved relate not only to the safety of the community, but to the protection of well-meaning and law-abiding citizens, who strive to carry out the letter and spirit of a statute.

The Health Board as the custodian of the health of the people makes it obligatory on the part of physicians attending suspicious cases of contagious diseases, to report the fact to the said department without delay, in order that proper means may be taken to prevent epidemics. Although the State has no constitutional right to force a physician to do so without recompense, the physician in his turn has tacitly submitted to the imposition rather than openly interfere with a regulation which on its face is calculated to benefit the public at large. The Drs. Purdy conformed with the law regarding a case in their practice. They were called to see a woman with a suspicious eruption and with other symptoms attending the invasion of small-pox. They reported the case to the Health Board. Their diagnosis was confirmed by a member of the Health Department, who by the authority invested in him as agent of the Board, ordered the patient to be transferred to the small-pox hospital. After a stay of two days in that institution the case was said not to be one of variola, and the patient was discharged. Thereupon the said patient sues the physicians for damages to the amount of $10,000. The result of the trial was a verdict of $500 against the defendants.

There were the best of grounds from the symptoms presented at the time of examination for believing the case to be one of small-pox. So much was testified to on the trial by experts. No one acquainted with the skill and experience of the medical attendants would doubt this, even without the bolstering of extra testimony. Nor is it conclusively proven that the case was not one of small-pox which ran a mild course. At best it was the opinion of one set of medical men against that of another. The jury, however, held that there was no excuse for any difference of opinion, and found for the plaintiff.

But allowing that the case was not one of small-pox, what culpability have the physicians in the matter? No law can assume that the judgment of a physician is infallible. Such a proposition is an absurdity on its face, and militates against every principle of law or gospel. No one should be held accountable for his opinion when it is one honestly rendered. The motive is the only thing to be questioned. In the case before us this was beyond criticism, and was clearly in conformity with a higher law than that of the State, that of conscience.

When the report was made, however, and the case delivered to the health authorities, the personal responsibility with the case, on the part of the physicians, was virtually ended. The Health Department represented the State which alone assumes the right of interfering with the liberty of the subject, and by virtue of its power in the premises, took the patient under its jurisdiction solely, and confined her in the small-pox hospital. But then the Health Department cannot be sued. The only seeming chance for redress by a plaintiff for a supposed wrong of this sort, is to sue the physician whom he or she first called in, and who reports the case to the Board. The physician must, under penalty of a fine, report every suspicious case, and if his suspicions are not confirmed, even after the Health Board has taken charge of the case, he is fined or otherwise punished. The attending physician has nothing to do with sending any patient to the small-pox hospital. The Health Board takes the responsibility into its own hands and is alone accountable for damages. What encouragement or protection has any physician for conforming to such a law? It is one-sided from beginning to end; compelling the doctor, as a free and independent citizen, to use his time and his professional ability for the good of the State, not only without pay but without any protection against an ignominious penalty in case a jury shall decide that his unbiassed professional judgment was at fault.

Certainly something must be done to right this monstrous wrong. Already the Medical Society of the County of New York has taken the matter in hand, by showing a determination to test the case still further. There is no desire to cripple the usefulness of the Health Department or to curtail its powers. Such a course would be clearly against public policy. But while the law must be vindicated, the rights of the individual who assists in carrying out its provisions must be jealously guarded.

Unless the State protects the physician against just such penalties as have been inflicted upon the Drs. Purdy, medical men will not only hesitate to report suspicious cases, but may justly decline to take any course which may render them liable to such ignominious trials as the one in question. Certainly a very dangerous precedent has been established by the verdict. The time has apparently come when the martyr's stake can be used as the torch to light up the way to justice.

THE FIRST FRUITS OF CHARITY REFORM.

IT is always gratifying to see the fruits of labor. For months the RECORD has been engaged in a crusade against existing abuses in medical charity. It has given full and free discussion to the various phases of the ques-

tion. Each interested party has had its columns freely open to it, and fair opportunity to state its view of the case. Our aim has been to serve as a medium whereby there might result an interchange of ideas. While advocating no specific plan, we have always encouraged the good points of every plan proposed. In all these ways attention has gradually been drawn toward one existing agency, the efforts of which seemed to be of the greatest practicability. We refer to the Charity Organization Society.

The meeting held last week at the Academy of Medicine, under the auspices of this society, was a memorable gathering. It was the first effort, so far as we know, to bring together a representation of all the interested parties. One of the most interesting features was the freedom and frankness of discussion. The presiding officer, with commendable tact, held the speakers well down to the work in hand. The Charity Organization Society presented itself in the capacity of a clearing-house, through the agency of which there might be an interchange of information between all parties engaged in charitable work. The records of the society's labors speak for themselves. They are most commendable. They have demonstrated theorems regarding charitable work which cannot be ignored by those who are endeavoring to conduct such work upon the lines of true social science. The conclusions adduced are so in harmony with what has so often been expressed in these columns that we may be pardoned for feeling that in this pioneer work our own part has been by no means a small one.

At the meeting alluded to there were four distinct classes represented: the hospital and dispensary trustee, the attending physician, the physician—representing the rank and file of the profession who are not interested in dispensary work (except in so far as it is doing them an injustice)—and the benevolent citizen at large. The gentlemen in attendance were representative men of these several classes in the community, and the tone of their discussion bore out these facts. A wise proceeding was the limitation to a small number of the committee upon whom devolves further action in the work so auspiciously begun. The majority of representation was justly and generously given to the medical profession, who are the greatest sufferers under the present faulty methods of management. They have done more than any other one class to inaugurate the present agitation. Upon their conduct depends future success. The present abuses affect the hospital and dispensary trustee so distantly that from them much cannot be expected. To the average physician these abuses come nearer home. They affect his pocket-book directly. The meeting showed conclusively how deep the feeling on this question has been in the minds of the profession at large. The denunciation of some medical charities whose methods we have lately had occasion to criticise showed that our words had met with a response which will not spend itself in mere words.

From the statements made by the Charity Organization Society, we know that at least one-third of all who apply at our medical institutions for aid are unworthy of free treatment. On the part of the profession it was adduced that the average physician spends at least one-third of his time in charitable work. Representatives were present from several institutions which through the Society have sought information concerning the worthiness or unworthiness of those applying for aid. They have made a fair trial of the Society's resources. The latter when weighed in the balance have not been found wanting. The practicability of the methods employed has been amply demonstrated.

So the first blow has been given to the entering wedge. Many details await arrangement. The conflicting interests of various institutions, with their respective staffs, must be adjusted to each other. This will require time, but it can be done. The work must be thorough, in order to be lasting. No temporary or half-way measures will answer. All parties interested must be accorded a fair hearing. The cheering feature about the whole matter is that at last the community has become aroused to its social peril under present charitable methods. Now can concerted action be taken that shall result in true and lasting reform. We do not believe that a more important meeting has ever been held than the one whose features we have chronicled. If anyone feels that injustice lies in the methods outlined, let him now speak or forever after hold his peace.

THE DANGERS OF THE COCAINE HABIT.

It is asserted by the *Medical and Surgical Reporter* that for a long time while Peru was a Spanish colony the cultivation of coca was prohibited on account of the disastrous effects which the indulgence in it brought upon the inhabitants. We have already, since the introduction of cocaine, learned what these disastrous effects are which the systematic use of that drug induces.

And it is quite time to sound a note of warning, positive and decided, to the medical profession, regarding the administration of cocaine internally.

To some persons nothing is more fascinating than indulgence in cocaine. It relieves the sense of exhaustion, dispels mental depression, and produces a delicious sense of exhilaration and well-being. The after-effects are at first slight almost imperceptible, but continual indulgence finally creates a craving which must be satisfied; the individual then becomes nervous, tremulous, sleepless, without appetite, and he is at last reduced to a condition of pitable neurasthenia.

Some physicians have already fallen victims to the cocaine habit, and quite a number have observed the pernicious effects of this habit upon their patients. Dr. A. B. Shaw, of St. Louis, in the *Weekly Medical Review*, relates experiences showing the effects of the substitution of the cocaine habit for that of morphine, and the evil influence of the continued use of cocaine upon the mind.

Dr. J. K. Bauduy, of St. Louis, has testified to the same effect.

Dr. Louis Bauer, of St. Louis, at the last meeting of the Mississippi Valley Medical Society, described the effects of cocaine on an inebriate. The alcohol habit was destroyed, but a cocaine habit substituted.

The patient, says Dr. Bauer, would take ten grains at one injection. The action of the cocaine ensued in from fifteen to twenty-five seconds, arriving at its height in less than an hour; in two hours the effects were almost en-

tirely gone, and reaction gradually followed. The drug had a very decided and marked effect upon the heart, the pulse rising quickly from its normal standard to one hundred and twenty or one hundred and thirty beats per minute. The cocaine destroyed appetite; it also produced obstinate constipation, lasting many days and hard to overcome. The secretion of urine ceased for the time, and the sexual function was also suspended.

Dr. Bauer thinks that the cocaine habit is at least preferable to the alcohol habit. We believe that it will probably kill more quickly, if that is an advantage.

That cocaine, though often well tolerated, is sometimes poisonous in not very large doses, appears evident from a case reported in the *Chicago Medical Journal*, by Dr. G. W. Kennicott. A young woman, twenty-five years of age, of good constitution, snuffed up about three grains of muriate of cocaine into her nostrils. In fifteen or twenty minutes she became dizzy, her vision became dark, a sinking sensation occurred, with great weakness. When the doctor was called he found the patient in a semi-comatose condition, from which she was easily aroused, and when so aroused her mind was clear. Her temperature was above normal. Her skin was hot and dry. The radial pulse was very rapid, and so weak as to be scarcely discernible. Her pupils were widely dilated. Deglutition and articulation were difficult. There was some dyspnœa. She complained of dryness of her fauces and a bitter taste in her mouth. She complained also of cold shivers, and her teeth chattered, although her temperature was still above normal. Later she became drowsy; her eyes were closed and the muscles of her face affected. There was great weakness; she could not support her head. There was dyspnœa, but it was not severe. There was some nausea, but she did not vomit. She recovered in about three hours under stimulants (brandy and ammonia) and digitalis.

Dr. Merriman writes to the *Ohio Medical Journal* that he has lately seen a gentleman who had been taking cocaine for four months for sick headache, beginning with a drachm of the four per cent. solution hypodermically per diem, and gradually increasing this till at last he was found to be taking from five to seven drachms a day. He was very weak, with a pulse of 100, and his mind was wandering somewhat, as in delirium tremens.

INFLUENCE OF OZONE ON HEALTH.

The recent paper by Dr. Daniel Draper, of the New York Meteorological Observatory, in which he practically accused ozone of being the cause, or at least the predisposing cause, of pneumonia in New York, has given rise to discussions relating to the hygienic value of ozone in the atmosphere which may eventually throw considerable light on this disputed subject.

It is well known that plants exhale ozone, and if this substance is a predisposing agent to disease the danger of keeping flowering plants in the apartments of a house, especially bed-rooms, becomes apparent.

We are indebted to Dr. Anders and Dr. M. B. Miller for a series of observations pointing to the class of plants which exhale the most ozone, the conclusions showing clearly that it is only flowering plants which have this property, and it was noted that those possessing odoriferous blossoms have this function to the greatest degree.

The result of most of the experiments tended to prove that odorous flowering plants are energetic ozone producers, but that non-odorous possess the function in but a slight degree, the former being more active than the latter. Those, therefore, who believe in Dr. Draper's hypothesis that there is some connection between the quantity of ozone in the atmosphere and increased death-rate from pneumonia, will do well to keep all flowering plants from their dwelling-rooms.

Ozone is found in pine woods, and was considered of such hygienic value that people went miles to breathe it. It is also present in the greatest abundance at the seaside, and in country places noted as health-resorts, and no one has hitherto suspected it of having a dangerous influence.

Chemists show that ozone rarely averages more than one seven-hundred-thousandth part, by volume, of atmosphere. The quantity present being greater in spring than in winter it might be thought that such a small proportion would be inappreciable, but small as it is it certainly makes its presence felt, for in its pure state ozone undoubtedly acts violently on the lung tissue, and it is known to oxidize substances rapidly which resist indefinitely the action of oxygen.

To test the value of Dr. Draper's theory careful records should be kept of the various observations throughout the world, and we trust that such a course will find favor among those in a position to carry out this suggestion.

WHY DOCTORS' BILLS ARE SOMETIMES UNPAID.

One reason why bills of physicians are unpaid is negligence in collecting them. This is especially the case when mechanics and other persons of limited incomes are treated. Despite the temptations which constantly beset the honest clerk, and others of his ilk, to dodge pecuniary responsibility through the many avenues of medical charity, there is at first an inclination to pay the doctor, if reasonable opportunities are offered for so doing. Too often, however, the medical attendant, actuated by false pride on one hand and an eagerness for business on the other, allows the money question to be in abeyance until the bill becomes relatively of startling size. The clerk and mechanic, as a rule, are persons who are accustomed to pay small bills, and to do so frequently. They themselves are paid weekly, and if provident, calculate their expenditures regarding board, room rent, clothes, and family necessities to a nicety. They belong to the pay-as-you-go class, although their business is on a small scale. The trouble, however, is that the family physician generally places himself above that scale and suffers accordingly. If his bills were presented even weekly he might have a chance to be served with the same consideration as the grocer, the butcher, and the baker. But he believes it unprofessional to be pecuniarily concerned, and the consequence is that the patient gets into the habit of believing that the doctor's bills are the hardest of all to pay. It does not appear to him that there is so much necessity about it. The doctor by his indifferent manner gives him to understand that there is no pressing necessity about it, and the patient acts ac-

cordingly. The bill consequently runs on until in the course of weeks and months of attendance it amounts to possibly fifty dollars or more. The patient paying week by week for what he is taught to believe by the ordinary tradesmen are his cash necessities has nothing left for the forced luxury of medical services, the large bill becoming a millstone about his neck. If he reasons with himself he must acknowledge that the dues are just, but how to get blood out of a stone is a dreadfully perplexing problem with him. He may possibly commence to economize, in order to offset what he coaxes himself to believe is an infliction, for few men receive a doctor's bill joyously. But pressing necessities for ready cash in his household present themselves and offset his best intentions. The medical attendant in the meantime sends his collector. The latter always arrives at an inopportune moment. He is generally as much out of place under the circumstances as is the skeleton at the feast. He is sometimes not even treated as a friend who comes to help the impecunious sufferer out of difficulties. His purer motives are misinterpreted, and his smiling overtures are received with studied coolness. If he talks of discharging obligations to the doctor, the good wife, who was once sick, is now well enough to take her part. The visits were made oftener than was necessary, at least so she now thinks, and the charges were exorbitant; at all events the doctor must be patient until they get the money. But alas! the medical attendant waits in vain, even long after the enterprising collector has given up the case. Little Johnny is taken sick in due time. The doctor is sent for and will not come. The family are now righteously angry. Then the retaliatory spirit asserts itself. What might have been treasure on the earth for the expectant creditor, has been transferred to an account that can only be collected hereafter. Johnny's father feels indignant and independent. Hereafter he will do his doctor business on cash principles, and he takes Johnny to the Out-Patient Department of the New York Hospital, pays his dollar and takes his choice. His pretended poverty is counterbalanced by his respectability, and he reproaches himself for not taking advantage of such opportunities before. The only way, under the circumstances, for the doctor to get such patients back again, is to secure an appointment in the Department, and be privileged to treat them for nothing.

Establishments for the Cure of Obesity.—Professor Oertel, of Munich, inventor of the method which Schweninger had so successfully applied to the Chancellor of the Empire, has set out for different places, in order to found establishments therein for the cure of patients suffering from diseases of the heart, fatty heart, obesitas universalis, etc. Baden-Baden, Ischl, the Semmering, and Abazzia on the Adriatic, are already chosen for this purpose. As climatic stations, Meran, Bozen, Gries, and others have already been opened.

The Lackawanna County Medical Society held its regular monthly meeting at Scranton, Pa., on November 11th, and passed a resolution "That the County Medical Society of Lackawanna County pass a series of resolutions condemning the action of the Committee of the American Medical Association, in soliciting support for its action regarding the International Medical Congress."

News of the Week.

The Sims Memorial Fund.—The cash subscriptions to the Sims Memorial Fund received by The Medical Record amount to $8,166.34, from which is deducted $406.43, for stationery, printing, postage, telegraphing, and commissions for collection. The balance, which remains on deposit with the United States Trust Company, and is subject to the order of the committee, is $7,759.91. This amount is considered sufficient to erect a suitable bronze statue to Dr. Sims, and the necessary steps to that end will be taken by the committee without further delay.

The Lancet on the International Medical Congress.—*The Lancet*, which has for a time been inclined to take a hopeful view of the Congress, and to make somewhat light of the defection and opposition to the present management, now says: "The reign of concord is not yet within sight even of the sanguine and of those who believe that, whatever the grievances of individuals and the importance of ethical questions, the great and supreme duty of every medical man in the United States at this moment is to devise a way of peace and such a restoration of harmony in the profession as will secure the success of the International Congress in Washington in 1887. In addition to such resignations as we lately mentioned, we have Professor Henry I. Bowditch's resignation of the vice-presidency, announced in a letter to the *Boston Medical and Surgical Journal*. Dr. Bowditch complains of the tone of the 'Journal of the American Medical Association.' His resignation is the more serious as he had hitherto resisted all pressure to join in previous protests against the action taken at New Orleans and elsewhere. Another vice-presidency has been declined by Dr. Henry F. Campbell, late president of the American Medical Association; and various other resignations are reported, such as those of Dr. E. O. Shakespeare, of Philadelphia, Dr. Henry G. Beyer, Dr. John Mason, Dr. Jerome S. Kidder, and Dr. J. M. Flint, U. S. N. We record this process of resignation with great grief."

Dr. Ferrán and his Cholera Inoculations.—The *Independencia Médica*, of Barcelona, has, says *The Lancet*, for the last six months "written up" Dr. Ferrán and his cholera inoculation *usque ad nauseam*, a very considerable portion of each issue being included in the so-called *Sección Ferránniana*. In that of October 11th there is a long letter from Drs. Ferrán and Gimeno to the Ministry, recounting their inoculation successes in Ondara, Santa Pola, and Cambrils, and a lengthy article drawing attention to this and comparing Ferrán with Koch as a discoverer, pointing out that, while the German scientist was promoted from an obscure provincial appointment to a most important post in Berlin, with a subvention of 100,000 marks wherewith to carry on his researches, Ferrán has been dismissed from his charge of the Tortosa infirmary. As if this were insufficient for one number, there is an annotation headed "From Malice or Ignorance," complaining that some periodical edited by medical men had insulted "the illustrious naturalist Dr. Ferrán," by referring to "that distinguished and disinterested

practitioner" as having pocketed several thousand dollars by his inoculations. After all this, which is a sample of what has been going on in the *Independencia* regularly three times a month, there has come a sudden stop. The last number that has reached us (that of October 21st) contains no *seccion Ferràniana*, no eulogy of "our distinguished *confrère* and friend," no anathema against his ignorant, jealous, and prejudiced critics in Spain and abroad—in fact, not a word about him from one cover to the other!

Something Worth Knowing.—The genial editor of the *St. Joseph Medical Herald* informs his readers beforehand that "the next issue of the *Herald* will be a daisy."

A Suicidal mania has broken out in Berlin, and the number of persons taking their own lives has of late been rapidly on the increase. On one day last week no fewer than seven cases of suicide took place in that city.

Dr. A. N. Bell has resigned his position as sanitarian to, and membership of, the Medical Board of the New York Infant Asylum.

Suit against a Gynecologist.—The *Boston Medical and Surgical Journal* says: "We regret to note that a prominent gynecologist of Boston has been subjected to a suit for malpractice by a woman whom he treated gratuitously, the claim being made that he performed an operation upon her against her will, the operation itself being unnecessary and improper. Moreover, that she was discharged from the hospital where she had been treated, at an unsuitable time. She lays her damages against the physician at $10,000, and for a like sum against the hospital."

Dr. A. D. Rockwell on Sheridan's Ride.—In the *Magazine of American History*, for November, is a wonderfully clever account, by Dr. A. Rockwell, of the famous ride of General Sheridan. It is too seldom that the busy doctor is tempted to venture into the realm of general literature and to try his descriptive powers on something besides strictly medical cases. When he does so, he not infrequently makes his mark by infusing into his composition all those rare traits for observation which are brought out by his professional training, and by exercising his cultured judgment in sharpening the salient points of his story. Dr. Rockwell has so far succeeded in all these respects that his graphically-told story is a masterpiece in its way. We only wish was twice as long.

The Treatment of Mastitis.—Dr. Paul F. Mundé writes: "Will you kindly state in your next issue that I have nothing to do with the question of priority between Drs. Harris, Milroy, Ranney, or any one else, as to the origination of the 'Treatment of Mastitis by Rest and Compression.' I do not know who first recommended this treatment. My letter to The Record, of September last, intended merely to prove that Dr. Milroy did not derive his inspiration from Dr. Harris through me, who then happened to be Dr. Milroy's visiting surgeon at the Maternity Hospital. I think I distinctly stated that so far as I knew, the priority of the method, as between Drs. Harris and Milroy, belonged to Dr. Harris, but that Dr. Milroy *might* have hit upon it independently. I would like to be left out of this controversy in the future, as I have nothing to do with it except as above stated. I hope this will satisfy your correspondent (Dr. Julius A. Post, of Lansing, Mich.), and all others who may believe that I wish to contest their claims of priority to the method in question."

Death of Dr. William Frothingham.—The community was deeply shocked to learn of the sudden accidental death, on November 18th, of Dr. William Frothingham, of this city. It appears that while cleaning a pistol it was accidentally discharged, the ball penetrating the eye thence to the brain and killing him instantly. Dr. Frothingham had lived on Washington Heights for twenty years and had been the leading practitioner in that part of the city during this time. Dr. Frothingham was fifty-five years of age. He graduated from the College of Physicians and Surgeons in 1854. He then served three years as interne in Bellevue, and was one of a party of young physicians and surgeons who went abroad for hospital practice in Paris and in some of the cities of Germany. Dr. Frothingham served in the war as surgeon in Colonel Ellsworth's regiment. He settled in this city in 1865. He was a member of the County Medical Society, of the Academy of Medicine, of the Pathological Society, of the Physicians' Mutual Aid Association, and of the Society for the Relief of Widows and Orphans of Medical Men. He was Visiting Surgeon at the Colored Orphan Asylum and the Juvenile Asylum, and was consulting physician at the Deaf and Dumb Asylum. He was noted for his charity, not only in giving professional services, but with his money. He was a man of deep religious convictions. As a physician he was eminently successful, being one of those, apparently, who are born to the Art.

The City Charge for Ordinary Obstetrical Cases ranges from fifteen dollars for the poorer to two hundred for the richer class of patients. The tenement-house population are treated gratis by the dispensaries.

Correspondence.

THE ROMAN CATHOLIC VIEW OF CRANIOTOMY.

To the Editor of The Medical Record.

Sir: His Grace the Archbishop of New York having requested me to answer your letter to him bearing date of November 3d, I take pleasure in complying with his wish, not only out of regard for the Archbishop himself, but also because I rejoice to see this question being agitated in so commendable a spirit by the members of your profession.

Catholic theologians have always been practically agreed as to the sinfulness of the practice of craniotomy. The reason is simply that the end, however good and desirable, can never justify or excuse the use of means which are unlawful in themselves. Now, the killing of a human being, even though that being is within a few moments of death from other causes, is wrong in itself, and has all the guilt of homicide. This proposition has never been doubted by Catholics. They all admit that, even in that case, dominion over life and death belongs to God alone. Hence the killing of a human being can never be adopted as a means for obtaining any end, even one so desirable as saving the life of a mother.

Up to a few years ago this teaching was received without question by all writers on ethics within the Church. Of late years, however—moved, no doubt, by the practice prevailing among some medical men—some few theologians took up the opposite side, and began almost to maintain the lawfulness of the operation, provided an attempt had previously been made to baptize the child *in utero*. The chief writers on this side of the question were Rev. Drs. Avanzini and Penuacchi, of Rome. Their arguments may, in the main, be reduced to two:

1. The killing of the child is indirect, so far as the intention of the operator is concerned, for he looks only to the safety of the mother. Now, all moralists hold that the *indirect* killing of innocent persons may *sometimes* be lawful, as, for instance, in the case where a general advancing to the attack, places hostages in the first rank of his army. It is then lawful for the defending army to fire, though they are certain that they will thereby slay their own friends.

2. Even if the killing of the child be supposed to be *directly* contained in the intention of the operator, it is merely the slaying of an unjust aggressor. The mother has a right to her life, and the presence of the child will deprive her of that right. It is true that the child is unconscious of this fact, and is in no sense morally responsible for it; but it still remains true that it is in reality an impediment to the mother's enjoyment of her right to life; and so, just as I may, when necessary for saving my own life, kill the lunatic who attacks me, though he be not responsible for his act, so may I take the life of the child to save that of the mother.

It must be confessed that, in spite of the ability of the writers who have presented these arguments for the lawfulness of craniotomy, they would seem to be no better than trivial sophisms. With regard to the first, it is evidently false to say that a means which is *directly* adopted for attaining an end, is only *indirectly* contained in the intention of the agent who so adopts it. It is not indeed the *final* object of his intention, but it is the *immediate* and *direct* object—even more direct, if anything, than the end which is ultimately intended. The parity with the case of the hostages does not hold, for there the defenders do not kill their friends in order that from their death the destruction of the enemy may result: this would be to intend the death of the innocent in itself. They aim at the enemy, though they know that their balls will certainly strike also their friends. With regard to the death of the latter, their intention is purely *permissive*. The same cannot be said of the intention of the craniotomist. He takes the death and dismemberment of the child as a means to secure the safety of the mother. His direct intention, therefore, is, first and foremost, to kill the child.

The second argument is due to an equal confusion of ideas. To constitute an aggressor, some positive act is required. The child is in its unfortunate position through no act of its own; it has come there by the course of nature, and is, in itself, wholly passive in the matter—indeed, generally speaking, the mother might with more propriety be called the aggressor on the rights of the child.

No doubt these considerations are quite obvious and familiar to your mind; but, in order to give an outline of the state of the question among Catholics, it was necessary for me to repeat them.

After causing much discussion, the matter was carried to the Holy Office of the Inquisition, at Rome. This is one of the congregations of cardinals appointed by the Holy Father to assist him in the details of administration in the government of the Church. The particular province of this Congregation includes all matters relating immediately to faith and doctrine. The question of craniotomy remained under careful consideration by the Congregation, not for weeks or months only, but for several years. On May 25, 1883, the Cardinal-Archbishop of Lyons submitted three questions to the decision of the Holy Office. On December 10th of the same year, the Congregation replied to two of the inquiries, and added: "The third question (referring to craniotomy) having been the subject of many other inquiries, made by other bishops, is still under consideration." On May 31, 1884, was sent to the same prelate the decision which has been copied by THE MEDICAL RECORD. There is, however, a slight inaccuracy in the translation given in that journal, though the error does not affect the substance of the reply. In the original nothing is said of teaching the operation in Catholic *medical* schools. The question decided by the Congregation is stated in the letter to be this: "Whether it can be safely taught in Catholic schools that the surgical operation known as craniotomy is lawful, when, etc.," the remainder being as given in THE RECORD. The schools referred to are theological schools, as the Cardinal of Lyons had put the question with reference to his own seminary.

The authority of this decision is absolute and binding on the conscience of all Catholics. When Roman Congregations decide questions without immediate reference to the Holy Father, their authority is subject to limitations varying with the nature of the matter decided, and with other circumstances. But in important cases, especially with regard to faith and morals, their decisions are often submitted to the Pope in person, and if they receive his approbation and explicit confirmation, they become a part of the authorized teaching of the Church, and cannot be denied by any Catholic. This is the case with the present decision, as is evident from its closing paragraph.

The exact *meaning* of the technical phrase, "tuto doceri non posse," may not at first sight seem so clear. The Congregation, as you will perceive, does not in express and precise terms declare the act to be sinful. But it will be quite evident, I think, that it does this equivalently. An opinion that cannot safely be taught is certainly not a *probable* opinion. Now all Catholic theologians agree that an opinion in regard to the lawfulness of an act cannot without sin be followed in practice, unless it have at least a solid probability in its favor; and this doctrine is authoritatively confirmed by the condemnation of the contradictory proposition by Innocent XI. I therefore have no hesitation in assuring you that all Catholics are bound in conscience to admit the sinfulness of craniotomy, and that any one who performs it, unless he be excused by ignorance of the real nature of his action, incurs the guilt of homicide.

I trust that what I have said will be sufficient to enable you to treat the Catholic view of this question, as you wish, fully and intelligently. If any explanation should have been obscure or defective on any point, I shall be most happy to supply the deficiency whenever you desire.

I remain, sir, very respectfully yours,

A. SABETTI, S. J.,
Professor of Moral Theology.

WOODSTOCK COLLEGE, HOWARD COUNTY, MD.,
November 7, 1885.

SURGICAL METEOROLOGY.—The *New York Medical Journal* says that, according to Dr. B. W. Richardson ("Asclepiad"), the time is favorable for operation: (1) When the barometer is steadily rising; (2) when the barometer is steadily high; (3) when the wet-bulb thermometer shows a reading of five degrees lower than the dry-bulb; (4) when, with a high barometer and a difference of five degrees in the two thermometers, there is a mean temperature at or above 55° F. The time is unfavorable for operation: (1) When the barometer is steadily falling; (2) when the barometer is steadily low; (3) when the wet bulb thermometer approaches the dry-bulb within two or three degrees; (4) when, with a low barometrical pressure and approach to unity of reading of the two thermometers, there is a mean temperature above 45° and under 55° F.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Adjourned Annual and Stated Meetings, November 23, 1885.

DANIEL LEWIS, M.D., PRESIDENT IN THE CHAIR.

LIABILITY FOR DAMAGES FOR REPORTING CASES OF CONTAGIOUS DISEASE.

THE *Comitia Minora* recommended that the Society request Drs. A. E. M. and A. S. Purdy, defendants in the case of Brown *vs.* Purdy, to appeal, the jury having brought in a verdict of five hundred dollars damages, and also that the sum of five hundred dollars, if necessary, be appropriated to aid in the proceedings.

The defendants reported what they believed to be a case of varioloid. The Health Board sent an inspector who saw the patient, and the Board ordered a removal to the Riverside (small-pox) Hospital. The plaintiff remained in the hospital a short time and was discharged, and subsequently brought suit for damages against the defendants, with the plea that she did not have varioloid.

On motion by DR. AGNEW the recommendation was received, and recommitted to the Comitia, with the authority of the Society to act in the premises.

The adjourned Annual Meeting then adjourned, and the Stated Meeting was called to order.

INAUGURAL ADDRESS.

THE PRESIDENT, DR. DANIEL LEWIS, delivered his inaugural address. To-day the Society began its eighty-first year. Organized before the days of Governor Clinton, upon a platform broad enough to embrace all that is desirable in the realm of medical science, professional advancement, and the public weal, it has steadily increased in numbers and influence till the present time.

It is to be expected, in fact is unavoidable, that vast changes occurring in society since 1805 should have affected the character of the medical profession favorably or otherwise. The profession of medicine, like other so-called learned professions, has its commercial side, whereby society contributes to its support for services rendered. In just the proportion in which the physician places the science and art of medicine first, and the question of dollars and cents afterward, is the practice of medicine

A PROFESSION OR A TRADE.

The President then directed attention to what seemed to be tendencies in our times to degrade the profession to a trade level. While "Listerine" and scores of other less pretentious quack preparations might be excellent, and certain brands of wines might be delicious, yet no professional man could afford to place himself in a position where a monetary consideration might be suspected. The indorsement of any proprietary remedy was certain to react unfavorably upon the legitimate practice of medicine. Our materia medica is extreme enough, and our therapeutics sufficiently perfected to enable any intelligent physician to prepare his own prescriptions, and avoid any possible recognition of the patent-medicine men who infest every community.

Numerous places for receiving patients are now tolerated which were not in vogue within the recollection of even the younger members of the Society. Men have been expelled from our ranks for having advertised private medical institutions for the treatment of diseases by the Swedish-movement cure, medical baths, and the like, whereas it now happens that infirmaries, sanitariums, homes for inebriates, etc., are described in the daily papers as being organized and conducted by the eminent Dr. Blank with a corps of competent assistants.

There is just ground for suspicion that an operation may have been undertaken either for the purpose of teaching the apprentice his trade or increasing a master workman's wages.

Removal of the ovaries may be useful, but if it proves to be popular, is there a probability of its being so extended or modified as to apply to diseased conditions not yet thought of in that connection, perhaps in both sexes?

There can be but one cause for this unseemly strife for medical business, and that is the overcrowded condition of our ranks, and the remedy lies in raising the standard of requirement for admission to practice. On a former occasion he had expressed to the Society the conviction that a

STATE EXAMINATION

was one of the most potent means within reach for securing these objects. That is the opinion of a very large majority of the best medical men of our land to day, and it would hardly seem necessary to discuss the question but for the fact that the superintendent of a lunatic asylum, who was also president of the New York State Medical Association, had publicly declared that the best interests of all concerned were subserved by the present methods of admission to practice.

The President then urged State examinations and a higher standard for admission and graduation from medical schools.

In closing, he expressed his appreciation of the obligations imposed by his unanimous re-election, an honor which he had no right to expect, but for which he was none the less grateful.

At the close of his address the President announced the following

COMMITTEES FOR THE ENSUING YEAR:

Committee on Hygiene—Dr. E. H. Janes, Chairman: Drs. Alexander Hadden, Cyrus Edson, John C. Peters, and W. L. Hardy.

Committee on Ethics—Dr. George A. Peters, Chairman; Drs. M. Blumenthal, C. C. Lee, W. T. Alexander, and E. Waitzfelder.

Committee on Prize Essays—Dr. F. R. Sturgis, Chairman; Drs. F. P. Foster and W. R. Birdsall.

Auditing Committee—Dr. P. A. Morrow, Chairman, and Dr. Gorham Bacon.

DR. NORMAN KINGSLEY presented a patient with

CLEFT SOFT PALATE,

tested his ability to articulate, so that the members could hear for themselves, and proposed to exhibit the patient at some future meeting, after he had been under treatment.

DR. MILTON JOSIAH ROBERTS then read a paper on

THE MECHANICAL AND OPERATIVE TREATMENT OF KNOCK-KNEE AND BOW-LEG,

in which he described methods of examination, new forms of apparatus, and new operations, etc. He objects strenuously to the use of subcutaneous saws, and to chisels for dividing the bone, and recommends the electro-osteotome, an elaborate instrument of his own device.

Dr. Roberts illustrated the operation of this instrument, and also exhibited another, designed for determining the width of the base of the wedge to be removed from a crooked bone, in order to make it straight, and called the gonometric bone-gauge.

THE PRESIDENT announced the death of Drs. E. B. Warner and William Frothingham.

THE SECRETARY read a communication received from the Board of Health announcing that the

WILLARD PARKER HOSPITAL,

at the foot of East Sixteenth Street, is open for the treatment of cases of such contagious diseases as scarlatina, measles, and diphtheria.

The Society then adjourned.

NEW YORK STATE MEDICAL ASSOCIATION.

Second Annual Meeting, held in New York, November 17, 18, 19 and 20, 1885.

(Continued from page 580.)

THURSDAY, NOVEMBER 19TH—THIRD DAY—MORNING SESSION.

THE Corresponding Secretary announced that 220 members had registered up to the present time. The Nominating Committee reported the following nominations of

OFFICERS FOR 1885–86.

President—Dr. E. M. Moore, of Monroe County, Fourth District.

Vice-Presidents—First District: Dr. William Gillis, of Franklin County; Second District: Dr. H. C. Van Zandt, of Schenectady County; Third District: Dr. F. Hyde, of Cortland County; Fifth District: Dr. D. Guernsey, of Dutchess County.

Recording Secretary—Dr. Caleb Green, of Cortland County.

Corresponding Secretary—Dr. E. D. Ferguson, of Troy.

Treasurer—Dr. John H. Hinton, of New York.

Members of the Council—At Large, Dr. John Shrady, of New York; First District, Drs. E. M. Lyon and Ira H. Abell; Second District, Drs. R. C. McEwen and Thomas Wilson; Third District, Drs. F. Hyde and F. W. Ross; Fourth District, Drs. Darwin Colvin and S. T. Clark; Fifth District, Drs. J. W. S. Gouley and E. S. F. Arnold.

The report of the committee was accepted, and the above-named officers were elected unanimously.

THE REPORT OF THE LIBRARY COMMITTEE

was then read. It was stated that about 3,500 volumes and 4,000 pamphlets had been received.

Dr. FELL, of Erie County, read a paper entitled

SOME ETIOLOGICAL FACTORS IN THE ACNEFORM DISEASES.

The author differed from most authorities as to the value of the *acarus*, or *demodex folliculorum*, as a pathogenetic factor of some, at least, of the acneform diseases. He thought that their almost constant presence in the pustules and in the free pus was a fact of considerable importance, although he was not prepared as yet to assert that they were the real and sole cause. They were found free in the pus and not in the sebaceous matter only. He then gave the results of a number of microscopical examinations of the contents of the pustules in a case of acne, in which he found the parasites almost invariably present. His treatment, which had been very successful, was directed to the destruction of the demodex.

Dr. E. G. JANEWAY, of New York County, then read the

ADDRESS ON PATHOLOGY.

We are witnessing now, the author said, a pathological revolution, and the strides made in the study of bacterial pathology are great. There are yet, however, many problems awaiting solution, one of the most important of which is that of the *de novo* origin of infectious diseases. Have the specific germs of typhus and typhoid fever a habitat outside of the body? The speaker thought it was possible that, as regards the latter disease, the germ might so live and propagate itself. He insisted upon the necessity of the careful observation and study of diseases arising, apparently *de novo*, in isolated places. Another important question is that of the prevention or mitigation of disease by inoculation with attenuated virus. While on this question, the speaker said that his experience had been that vaccination three days after exposure to small-pox would not prevent an attack of the latter disease; vaccination was delayed and the patient had an attack of small-pox, though a mild one. He explained that the Germans were ahead of other nationalities in the matter of pathological investigations, largely because of the liberality of their government in fostering scientific studies. Young men were stimulated to work in the hope of obtaining the honors of a professorship. Young men in this country were deterred often from undertaking practical scientific studies by the great cost of the necessary apparatus, which was double that of the same instruments in Germany.

At the request of several members Dr. Janeway made also some remarks on the use of

OXYGEN GAS IN PNEUMONIA.

He said it was of great value if given at the very commencement of cyanosis, but if begun later, after cyanosis was fully established, it was less useful. It should be repeated as often as the blueness of the skin reappeared.

AFTERNOON SESSION.

Dr. WILLIAM W. SEYMOUR, of Rensselaer County, read the first paper, entitled

A CASE OF GALLSTONES, PATENT AND CONCEALED—EXPLORATORY LAPAROTOMY—AUTOPSY EIGHT WEEKS LATER.

His conclusions were that the operation of incision of the gall-bladder was justifiable in suitable cases, and preferable to excision.

Dr. NELSON L. NORTH, of Kings County, then presented a paper on the

THERAPY OF THE CHLORIDES; ANTISEPSIS A PROMINENT AND IMPORTANT FACTOR IN THEIR MEDICINAL ACTION.

He regarded disease as a result of changed physiological processes, and due to the presence of disease germs; and if this be so, antisepsis is the key to the treatment of infectious disease. The efficacy of the mercurial chlorides in syphilis, dysentery, gonorrhœa, and other affections, rests in their power of destroying micro-organisms. It is probable that the action of the chloride of iron in Bright's disease will be eventually explained in the same way. The benefit of muriate of ammonia is doubtless due to its antiseptic action. In diphtheria, he said, the first thing should be to destroy the cause by tincture of iron and chlorate of potassium, and after this, if necessary, brandy and nourishing food may be given.

Dr. PETERS, of Albany County, said that he had never lost a case of diphtheria since he began to give the bichloride of mercury, one-thirtieth grain, alternating with tincture of iron every hour.

Dr. ROBERT NEWMAN, of New York County, followed with a paper entitled the

CAUSES OF FAILURE IN THE TREATMENT OF URETHRAL STRICTURE BY ELECTROLYSIS.

He said his success had been so great in his own cases that he was astonished when he heard that others had failed in this method of treatment. He was led to investigate the causes of these failures, and had come to the conclusion that these were three: 1. Incompetence of the operator; he should be not only a good surgeon, but a good electrician. 2. Incorrect diagnosis; electrolysis will not cure spasms of the urethra or enlarged prostate. 3. Faulty instruments; electrolysis properly handled cannot fail.

Dr. G. H. MEIER, of New York County, regarded the operation as one of great value, and destined to win a place for itself in the therapy of urethral stricture.

Dr. T. H. MANLEY, of New York County, thought

the operation was not one that could be undertaken by every one, as the author had said it required an expert in electricity to perform it successfully, and he thought it was a dangerous matter to recommend its general adoption by the profession at large.

Dr. W. W. Seymour, of Rensselaer County, read a paper on

THE DIAGNOSIS AND TREATMENT OF PELVIC HÆMATOCELE.

This affection occurs during the period of menstrual life, and is as common in nulliparæ as in those who have borne children. The author detailed the causes and mode of origin of hæmatocele, and the symptoms of this condition. A certain diagnosis is impossible before the expiration of several hours. The indications for treatment are to control hemorrhage and diminish shock. If there seem to be no tendency of the effusion to increase, rest is all that is necessary; but if it do increase and press upon the neighboring organs, aspiration of the uncoagulated portion is often beneficial; when suppuration has occurred, free opening is necessary; this should be done through the vagina or the abdomen, but never through the rectum.

The following papers were read by title: "A Case of Poisoning by Two Grains of Strychnia—Treatment, Chloral Hydrate and Coffee," by Dr. Wm. Fitch, of Tompkins County; "The Treatment of Abscess," by Dr. J. D. Rushmore, of Kings County; "Chronic Catarrhal Gastritis: Fatal from Complication of Sudden Enlargement of the Thyroid Gland," by Wm. H. Thayer, of Kings County; "The Proper Disposition of Street Sweepings, Ashes, Swill, and Garbage in our Cities," by Dr. Albert H. Briggs, of Erie County; "Ergot—Its Uses and Misuses," by Dr. J. K. Leaning, of Otsego County; and "Nutrition in Lithæmia," by Dr. Charles G. Stockton, of Erie County.

The session was then adjourned to meet in the morning at the Carnegie Laboratory, on East Twenty-Sixth Street.

Friday, November 20th—Fourth Day—Morning Session.

The meeting was called to order in the Carnegie Laboratory, at 10 o'clock, by Dr. Wm. Gillis, of Franklin County.

Dr. Samuel W. Smith, of New York County, read a paper entitled,

THE HISTORY AND TREATMENT OF THIRTY CASES OF DIPHTHERIA.

These cases were treated according to the method advocated by Dr. Billington. This consists of the internal administration, alternately, of tincture of the chloride of iron in glycerine, and chlorate of potassium; of thorough irrigation of the affected parts of the pharynx and nares with a solution of common salt, to which Dr. Smith adds borax; and of spraying the fauces with lime-water and carbolic acid. Of these thirty cases there were five deaths. The author was not attached to tracheotomy in laryngeal diphtheria. He was not a dualist, but inclined to the belief of the identity of membranous croup and laryngeal diphtheria. He thought that those who claimed to cure every case of diphtheria were not to be relied upon, but dealt rather with fiction than fact. Dr. Smith had given no alcohol or quinine in these cases, but kept his patients upon a strict milk diet.

Dr. Hannan, of Sullivan County, did not think much of the paper, and said no one in New York City, professor or otherwise, knew anything about diphtheria any way.

Further discussion was participated in by Drs. Garrish, Kneeland, Fell, and others.

THE REPORT OF THE COUNCIL

was then read, in which it was announced that the next meeting of the Association would be held in New York City, in November, 1886.

Dr. George T. Harrison, of New York County, followed with a paper on

PERI-UTERINE HÆMATOMA,

in which he described the principal symptoms, and dwelt upon the differential diagnosis.

Dr. John Shrady, of New York County, reported a case of

CANCER OF THE KIDNEY,

occurring in a young child. Malignant disease of this organ, the speaker said, is found relatively often in children under five years of age. The diagnosis of the affection, in infants and young children, is comparatively simple since malignant disease of the ovaries or spleen may be excluded. The idea that carcinoma is exclusively a disease of advanced life is erroneous. A point of value in the diagnosis is the position of the colon lying in front of the tumor; another is the astonishingly rapid increase in the size of the new growth. The other organs are displaced, and the pressure upon the lungs causes sometimes intense dyspnœa. Hematuria is supposed to be a pathognomonic symptom, but the author had not observed it in three cases which he had seen. One striking appearance was the prominent and somewhat varicose condition of the superficial abdominal veins. The pain may be severe and constant, or it may be intermittent.

Dr. Fell, of Erie County, extended an invitation to the members to be present at the next meeting of the

AMERICAN MICROSCOPICAL SOCIETY,

to be held at Chautauqua, in August, 1886.

The Committee of Arrangements announced that at the next meeting, in 1866, sessions would be held for three days only, and most of the scientific work would be confined to the morning and afternoon, leaving the members more at liberty to seek recreation in the evening.

The following papers were read by title: "The Modern Aspect of Therapeutics," by Dr. Thomas H. Manley, of New York County; "The Vectis in Cross-births," and "Pessaries and their Uses," by Dr. Jacob Hartmann, of New York County; "Notes on Contracture of the Bladder Consequent upon Cystitis," by Dr. J. W. S. Gouley, of New York County.

Afternoon Session.

This session was devoted to a

DEMONSTRATION OF THE PLASTER-OF-PARIS JACKET

in its application to the treatment of spondylitis and lateral curvature, by Dr. Lewis A. Sayre, of New York County.

The Session was then adjourned until evening.

Evening Session.

Dr. Frederic S. Dennis read a paper on

THE ACTION OF MICRO-ORGANISMS UPON SURGICAL WOUNDS, WITH DEMONSTRATIONS.

The following classification of micro-organisms was given: 1. Spherobacteria, or bacteria in spheres. 2 Microbacteria, or bacteria in rods. 3. Desmobacteria, or bacteria in straight filaments. 4. Spirobacteria, or bacteria in spiral filaments. 5. Fungi. Nos. 1, 2, 3, and 4 belong to Schizomycetes. To 5, belong Blastomycetes.

Later in the evening, the annual banquet of the Association was served at the Murray Hill Hotel. Dr. John P. Gray, the retiring president, acted as toast-master. The first toast, "The growth of our Association," was responded to by Dr. H. D. Didama. "Our District Associations" was responded to by Dr. Frederick Hyde. To "Our Future" response was made by Dr. E. M. Moore. "The Press" was represented by Mr. McElroy, of the *Brooklyn Times*, and Dr. Simeon Tucker Clark read a poem entitled "Life and Death."

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting, November 19, 1885.

ABRAHAM JACOBI, M.D., PRESIDENT, IN THE CHAIR.

A SECTION on Laryngology and Rhinology was created.

THE BOARD OF HEALTH.

A letter from James Gallatin, Esq., addressed to the President, was read, in which the writer directed attention to certain facts in connection with the action of the Board of Estimate and Apportionment which might impair the usefulness of the Board of Health by reduction of salaries and dismissal of valuable medical members. Some reduction could be borne without inconvenience. The letter urged upon the Academy the propriety of expressing the desire that the old and tried medical members of the Board be retained.

On motion the letter was accepted.

DR. GOUVERNEUR M. SMITH offered the following preamble and resolution, and moved their adoption.

Whereas, It is a generally recognized fact that the value of the work of the Health Department of the City of New York depends largely on the presence and training of competent medical men; and

Whereas, It has been declared expedient that some reduction in expense should be made during the coming year; be it therefore

Resolved, That it is the sense of the New York Academy of Medicine that said reduction should be effected in such a way as not to impair the usefulness of the department, either by dismissal of competent and experienced physicians now years in the service, or by lowering their salaries below a fair and equitable rate.

With regard to the wisdom of reducing the appropriation for the use of the Health Department he had nothto say; but concerning the medical element of the department the profession certainly had the right to give an expression of opinion.

DR. FORDYCE BARKER seconded the resolution, and said that how far expenditures had been injudicious, and how far appropriations might be diminished, he was utterly unable to say; but as regards the resolution there was no doubt that, to secure efficient work, men fully competent to discharge the duties of the offices must be employed, and of such integrity that they were worthy of being employed and amply paid for their services.

The resolution was unanimously adopted.

DR. HENRY D. NOYES then delivered the Anniversary Discourse (see MEDICAL RECORD, page 589), on

PATHFINDING IN MEDICINE.

DR. FORDYCE BARKER, at the close of the address, gave a brief and entertaining review of the history of the custom of having an anniversary discourse delivered before the Academy, and made pleasant reference to those by the late Dr. Francis in 1847, and by the late Dr. J. Marion Sims in 1857, who included in his oration the history of the silver suture. While Dr. Sims was speaking, one of the ladies sitting by the side of Dr. Barker asked "What is this silver suture?" to which Dr. Barker replied that it was "a new-fashioned back-stitch." Dr. Barker also referred to the reference made by Dr. Noyes to the practicability and desirability of making the Academy the great centre of advanced study in medicine, and also spoke of it as one toward which the profession, not only of the United States, but of the world, might turn with the assurance that their desires and hopes would be fully realized.

He moved that the thanks of the Academy be tendered to the orator for his suggestive, interesting, and able address. Unanimously carried.

The Academy then adjourned.

SECTION IN PRACTICE.

Stated Meeting, November 19, 1885.

ALFRED L. LOOMIS, M.D., LL.D., CHAIRMAN.

DR. R. C. M. PAGE read a paper (see MEDICAL RECORD, November 21st)

ON BRIGHT'S DISEASE.

DR. FRANCIS DELAFIELD opened the discussion, and said that Dr. Page's paper brought before us a subject which, although it had been gone over so many times by so many different writers, always remained one of interest. The different forms of Bright's disease of the kidneys constituted some of the commonest diseases of civilized life. Every day we were brought face to face with them and were made to feel more and more how little we really knew concerning them. There was, perhaps, no set of lesions or of symptoms which had occupied the attention of so many of the best minds in the profession, and yet we were obliged to acknowledge that we could not fully understand them, nor did we know fully how to treat them.

It had always seemed to him that the first step toward improvement in our knowledge of kidney diseases lay in an accurate classification, and although one after another had made an attempt to do this, he thought it must be acknowledged that no one had yet made a classification that was acceptable to all. The sort of classification that one needed would depend partly on the particular way in which one was brought in contact with these affections. For clinical purposes the simple division into acute and chronic Bright's disease, and the further subdivision of chronic Bright's disease into the cases in which the kidneys were atrophied, and those in which atrophy was not present, certainly answered a reasonably fair purpose; it was a practical division, and one which corresponded fairly well with ordinary clinical experience.

But if we went a little further than this, and looked at the kidneys of persons who had died of either acute or chronic Bright's disease, then it would be found that all kidneys were not the same. Again, when we endeavored to put together the clinical symptoms in a number of cases and make them correspond to the varieties of exact anatomical changes, it would be found that our success would be somewhat limited.

Take, for example, what might be included under acute Bright's disease. Anatomically the acute affection included two different lesions: one in which the inflammatory changes were confined to the epithelium of the tubules and of the Malpighian body; this form might be called *tubular nephritis*, or *parenchymatous nephritis*, and anatomically the lesion was distinct enough. On the other hand, there were examples of acute Bright's disease in which, in addition to the changes in the epithelium of the tubules and of the Malpighian bodies, there were changes in the stroma, consisting in an infiltration of the stroma with serum and white blood-corpuscles. In these cases also it would be found that the change in the epithelium of the Malpighian bodies was very much more marked than it was in the first set of cases; this second set of cases might be called *acute diffuse nephritis*, and we might separate the special ones in which changes in the epithelial cells of the Malpighian bodies were most marked and call those *glomerulo-nephritis*.

These three different conditions constituted a very great majority of all the cases of acute Bright's disease. There were a very few cases, however, in which the lesion was almost entirely interstitial, and in which there was scarcely any change in the epithelium of the tubes, and but very little change in the Malpighian bodies; this, anatomically, had been called *acute interstitial nephritis*, but these cases were very rare.

But when we studied the cases of acute parenchyma-

tous, or acute tubular, acute diffuse, and acute glomerulo-nephritis, it would be found, after all, that their clinical histories were very much the same. There were many cases which it would be entirely impossible to distinguish during the life of the patient. Generally speaking, the cases of parenchymatous nephritis were less severe, and those of acute diffuse and glomerulo-nephritis were more severe; yet cases of parenchymatous nephritis which were quite as severe as those of acute diffuse nephritis were occasionally seen, and therefore, for clinical purposes, this anatomical division did not help us very much.

If a patient had acute Bright's disease, it was readily enough recognized during life; but we were not, as a rule, able to make a differential diagnosis between an acute nephritis which involved only the tubes and an acute nephritis which involved both the tubes and the stroma of the kidney. The comparatively rare cases of pure interstitial nephritis were so few that we could not speak of them with any certainty. He had found but few recorded by other observers, and had seen but few cases himself. Their clinical history was somewhat different from that of other cases of acute Bright's disease, yet he had not seen enough of this form of the affection to fully warrant him in trying to give an outline of the clinical picture.

When we came to the cases of the chronic affection, it was found that the general name, chronic Bright's disease, answered a very good clinical purpose. It covered a large number of cases of renal disease in which the symptoms were essentially the same, varying in degree of development in different individuals. The fact that in some of the cases the kidneys became atrophied, with very marked changes in the interstitial tissue, had very properly led to the separation of these kidneys from other forms of Bright's disease as a particular variety, and the *atrophic form of the affection* was well known. The clinical course of this form of chronic Bright's disease was apt to be long-continued, the early symptoms were often obscure, and there was a disproportion in many cases between the amount of kidney lesion and the symptoms during the life of the patient. Yet the kidney lesions remained, and the patient was capable of getting better, and then worse. The symptoms extended over a long period of time, the body had time to get accustomed to the gradual change in the kidneys, and finally, we may find kidneys which weigh not more than three or four ounces without having given rise to any renal symptom whatever.

Then, apart from these atrophic kidneys, there were a very considerable number of other cases of chronic Bright's disease which we were apt to group together rather loosely under the name of the *large white kidney*. These, again, had their own characteristic course, which was more acute and more likely to be attended by dropsy and acute symptoms of different kinds. Again, when we examined the kidneys more closely, we would find, in some of the cases of chronic Bright's disease, that the lesions were confined to the tubes and to the epithelial cells of the Malpighian bodies, and these cases might be called *tubular or parenchymatous nephritis*. Then we had the so-called atrophied kidneys, and with these were anatomically to be grouped a number of kidneys which were not atrophied at all. In these cases changes would be found in both the epithelium of the tubes and the Malpighian bodies, and also in the stroma and in the arteries. It has become rather customary to call this form of the disease by the name of interstitial nephritis, on account of the great development of changes in the stroma. There would be no special objection to this name, in many points of view, if it were not that besides these kidneys there were those which were examples of real *interstitial nephritis*, in which the changes existed in the stroma alone, without changes in the epithelium of the tubes or in the Malpighian bodies. These cases, however, were of comparatively rare occurrence, but were sufficiently numerous to make it more convenient to classify these atrophied kidneys under the common name of *chronic diffuse nephritis*.

Another point to which Dr. Page had called attention was that particular group of symptoms belonging to kidney diseases, and commonly called *uræmia*. All were familiar with this group, consisting of cerebral symptoms—headache, restlessness, sleeplessness, delirium, stupor, convulsions, and coma—repeated and uncontrollable vomiting, and dyspnœa, apt to be excessive. These three—cerebral symptoms, vomiting, and dyspnœa—sometimes the one, sometimes the other, being most marked, belong regularly to a uræmic attack.

This group of symptoms appears as an acute condition which seems to demand medical interference, has attracted, and always will attract, attention, and our treatment always seems to be influenced to a considerable degree by our special views as to what the cause of these uræmic attacks may be.

Of course, it would be out of place at the present time to attempt any prolonged discussion as to what the real cause of uræmia may be. Most observers, however, had come to a choice of one of these conditions: either that the attacks are due to anæmia and œdema of the brain and its membranes, or that they are due to the circulation of urea or some other excrementitious substance in the blood, or that they are due simply to disturbances of the circulation.

The idea that uræmic attacks are due to poisoning of the blood by urea or other excrementitious substance is one which has taken a very firm hold upon the profession, and one which is felt in every-day practice. When a patient has been found in the uræmic condition, purging, sweating, and the use of diuretics have been, and still is, a routine treatment. Most of us have applied this routine treatment, and may yet use it, although we may not think very highly of it. All must have felt that, although it is the routine treatment, it is one which but seldom has any favorable effect on the patient.

Within a moderate number of years the drift of practice has been rather to break away from this routine, and to use remedies belonging to a different class, remedies which really act upon the circulation of the blood, and the good effect of which seems rather to indicate that these uræmic attacks are not due to any blood-poisoning, but are simply due to an abnormal distribution of the blood throughout the body; and the abnormal distribution seems to consist in that the brain, the lungs, the stomach, the kidneys, perhaps the liver, contain too small quantity of arterial and too large quantity of venous blood.

The plans of treatment which have been brought forward in later years, whether adopted by those who hold that the symptoms are due to disturbances of the circulation or not, do seem to point in that direction—for example, the use of opium. All of us have learned to look upon opium in the treatment of both acute uræmia and the more prolonged uræmic conditions as our great reliance. We have also learned that the more severe the uræmic attack, so much the larger doses of opium can be used, and that to do the most good we should administer it in the most sudden way, and that is by large hypodermic injections.

In other words, we use a drug that strengthens the force of the heart's action and relaxes any contraction of small arteries and capillaries which may exist.

In the same way we use the chloral hydrate, which is certainly very efficacious in the treatment of uræmic attacks, and it acts apparently by dilating the small arteries and capillaries.

In uræmic attacks in which the heart is found to be acting feebly, it is best to resort to those remedies which stimulate the heart's action.

In the uræmic attacks in which the heart's action, during the attack, is found too forcible, the best results are obtained with drugs which reduce its force.

The uræmic attacks which resemble angina pectoris,

being attended by spasmodic contraction of the small arteries, are best relieved by inhalations of nitrite of amyl and the administration of nitro glycerine.

It seems, therefore, that in the treatment of the acute and of the more chronic uræmic attacks we are learning more and more to place confidence in the drugs which do not eliminate a poison from the body, but which simply act upon the heart and upon the arteries.

Dr. William H. Draper said he was not prepared to discuss the comprehensive paper of Dr. Page in the ten minutes allotted, and would therefore confine his remarks to the method of treatment of the uræmic attacks.

His own experience had brought him to the same conclusion which had been expressed so well by Dr. Delafield. He confessed, however, that he was perhaps more or less under the dominion, in cases of the more acute cerebro-spinal symptoms ascribed to uræmia, of the eliminative treatment.

At the same time he was prepared to admit that his views with regard to the manner in which so-called eliminative remedies act was not, perhaps, by the elimination of any poison from the body so much as by their action upon the circulation. He thought that we might arrive by blood-letting, by brisk purgation, and by active diaphoresis, at the same results, so far as the circulation was concerned, which were obtained by the administration of opium, glonoin, and nitrite of amyl.

When, however, he was brought into contact with a case of uræmic convulsions, he was prone to adopt either blood-letting or brisk purgation in connection with opium. He thought that was the point which Dr. Page wished to make when recommending the pilocarpin with opium. Dr. Draper had not for some years used pilocarpin in cases of uræmia, partly because he had not had very marked success with the remedy, and partly because he had felt that it was a dangerous cardiac depressant. He had been more given to the use of brisk purgation and blood-letting; his experience with blood-letting had been chiefly in cases of puerperal convulsions.

In the treatment of the less alarming uræmic symptoms—the uræmic headache, dyspnœa, and vomiting—he had felt for a long time that opium was the sheet-anchor. He had not, thus far, had the success with nitro glycerine that he had obtained with opium. He knew of nothing which relieved uræmic dyspnœa so well as a hypodermic injection of morphine, and it was equally efficacious in the relief of uræmic headache.

Uræmic vomiting he looked upon as one of the most rebellious and troublesome of all uræmic phenomena, and while opium sometimes did give relief, he thought that it did not act with the same energy as in the other cases.

Dr. Heineman asked a question with reference to uræmia. Some patients, suffering from chronic Bright's disease, pass two or three times the normal quantity of urine, and while the proportion of urea is diminished, the total quantity daily is in excess of the normal. How is uræmia to be accounted for in those cases if it depend simply upon the presence of urea in the blood?

The Chairman said that if he were to answer the question he should say that in chronic uræmia patients become accustomed to the influence of the poison, if urea acted directly as a poison, and while at one given examination in twenty-four hours a patient might pass more than the normal quantity of urea, if the urine for a week or a month were examined it would be found that the quantity of urea excreted was less than normal. His impression was, that if urea acted at all, its effects were upon the circulatory system, and in the way of changes in the arterioles and capillaries, and not as a direct poison upon the nervous centres, and that the uræmic symptoms in chronic Bright's disease are the results of these changes affecting the blood-vessels.

Dr. Heineman said that his examinations were not single, but extended over a long period of time. He brought the fact forward simply as evidence that the term uræmia did not at all times apply; that it was not urea only which was retained in the blood, but that there were other elements which produced the symptoms called uræmic.

Dr. Page, in closing the discussion, said he had hoped that one point referred to in his paper would have been discussed, namely, the influence which chronic Bright's disease exerted on the safety in administering ether and chloroform as anæsthetics, and therefore on their inhalation for the purpose of controlling uræmic convulsions or relieving other uræmic symptoms.

"About fourteen years ago, in my private hospital, I closed the lacerated perineum of a woman who seemed otherwise in excellent health. Ether was administered, but she never entirely regained her consciousness, and died with well-marked symptoms of uræmic poisoning, about thirty-two hours after the operation. It was found that she had Bright's disease of the kidneys. Since then I have had at least five deaths to occur in public and private practice, and these, perhaps, might not have occurred had the importance of examining the urine been appreciated before the anæsthetic was given. I established the rule, when in charge of the Woman's Hospital, that the urine should be examined in every case before an anæsthetic was administered. The result was that in a number of instances unsuspected disease of the kidneys was detected, and the operation was performed with the aid of opium, and without an anæsthetic" (Emmet's "Principles and Practice of Gynecology," p. 730. First edition. 1879).

In a case of twin pregnancy occurring three years ago, in a young primipara, twenty-one years of age, and attended by me, dropsy was well marked, and she had albuminuria. As labor progressed slowly, and fearing that she might have convulsions, I at once called Dr. George T. Harrison in consultation. We agreed that she should be delivered with forceps without further delay. Ether was administered, and she was speedily delivered. There was no more hemorrhage than is usual in a normal case of labor. The patient, however, went into a profound state of collapse, out of which I had the utmost difficulty in bringing her by means of hypodermic injections of morphine and hot bottles placed about her extremities. Dr. E. D. Hudson, Jr., also saw this case with me afterward.

The topic of general discussion was,

IS CROUPOUS PNEUMONIA AN INFLAMMATION OR A FEVER?

The discussion was opened by Dr. William H. Draper, who said: "I feel as if I ought to apologize for consenting to open the discussion on this subject, for the reason that I have no settled convictions to offer in regard to the question as to whether croupous pneumonia is simply a local inflammation or the lesion of an essential, specific fever.

"In approaching the question, it is important to remember that all that we positively know about the nature of pneumonia is that it is anatomically an inflammation of the air-vesicles and bronchioles. When we go beyond this fact, and attempt to determine its cause, we leave the confines of positive knowledge and enter the illimitable realm of conjecture, or the more or less obscure nebula which surrounds the body of exact science and is yet unincorporated.

"The question before us is one which has occupied the minds of pathologists and clinical observers for many years. In a discussion which took place in this Academy, in 1865, I read a paper in which, with somewhat more zeal than I could command now, I advocated the theory of the essential nature of the fever in pneumonia. In 1881 an excellent paper was read by Dr. Sanders, of this city, on the same subject, advocating a similar view; and in the discussion which followed, if I remember rightly, several observers, among them Drs. Flint and Loomis, lent the weight of their authority to the theory that the

lesion of pneumonia bears the same relation to the fever that is borne by the lesions of the exanthemata to the fever which is their essential characteristic. The arguments in favor of this theory are familiar to you all. They are simply, the occasional epidemic prevalence of the disease; the independence, in the majority of cases, of the exciting causes of cold and dampness; the precedence of the fever to the lesion, sometimes by a period of one or two days; the occurrence, especially in young subjects, of more or less violent cerebro-spinal symptoms; the frequent association with the disease of nephritis; and the fact, which has always especially attracted my attention, that the beginning of defervescence is nearly, if not exactly, coincident with the maximum of extent and intensity of the local lesion. But interesting, and at first sight striking, as these arguments appear, if we examine them, we shall see that some of them will scarcely bear critical analysis, and that all of them are open to more or less objection, as proving that pneumonia is always a septic fever. The occasional epidemic occurrence of pneumonia may prove that it is an infection fever, but it could scarcely be held to prove anything more. The independence of many of the sporadic cases of the exciting causes of cold and dampness is certainly a striking fact; but the fact that the lesion occurs suddenly in acute alcoholism and after immersion, as well as after severe exposures to cold, is also striking, and goes far to prove that the disease may sometimes recognize a nervous origin.

"The precedence of the fever in the sequence of events in pneumonia is not inconsistent with the theory that the pyrexia is due to the inflammatory process in the lung. It is quite possible that it is coincident with changes which are not recognizable by physical exploration.

"The occurrence, especially in young subjects, of more or less violent cerebro-spinal symptoms is quite as explicable on the theory of reflex disorder as on that of direct irritation.

"The frequent association of nephritis with pneumonia is certainly suggestive of a common cause, and yet it is not unlikely that the nephritis is the result of changes in blood-pressure brought about by the pulmonary disease.

"The coincidence of defervescence with the culmination of the local lesion, as I stated, impresses me as the most striking proof of the analogy which exists between pneumonia and typhus and erysipelas, and yet here again we must not fail to observe that the critical termination of pneumonia is not the only termination. Some cases terminate by lysis. Still, the rule of sudden defervescence has no more exceptions, perhaps, than occur in typhus and erysipelas.

"I think we must conclude, therefore, that arguments drawn from the clinical history of the disease are insufficient to determine the question as to the essential character of pneumonia—as to whether it is primarily a pyrexia of septic origin, or a local inflammation, a tissue disorder determined by a variety of causes which act primarily upon the nervous system.

"The recent revelations of bacterial pathology lend a new interest to this inquiry, and very properly suggest a reconsideration of the origin of the inflammatory lesion in pneumonia. We shall find, however, if we trace the history of the monas pulmonale from its discovery in 1877 by Klebs, to the present time, that the first glow of enthusiasm created by the supposed finding of the key which was to unlock this particular pathological mystery has subsided into a somewhat frigid skepticism as to its claim to bear a causal relation to pneumonia. But perhaps the monas will survive its foes, and yet substantiate its title to recognition. It may not be unprofitable to sketch briefly the history of the coccus which is thought to be the determining cause of pneumonia.

"'The monas pulmonale' was first described by Klebs in 1877. It was found by him in the lungs and ventricles of the brain and had independent motion.

"Eberth, 1881, gave more details regarding their characteristics, and described them as diplococci. He found them in the lungs and pleural exudation.

"Koch, 1881, found them in the kidneys and lungs, and gave further morphological details.

"Friedländer, 1882–83, described ellipsoidal cocci one millimetre long; also round cocci occurring chiefly in pairs, but also forming chains, found in the alveolar and in the bronchial fibrinous exudation. He has never seen them in the protoplasm of the cells.

"Leyden and Günther, 1882, found them in the fluid obtained from puncturing the lungs with a hypodermic needle.

"Griffini and Cambria, 1883, made pure cultures of the micrococci found in the *blood* of cases of pneumonia, and caused fatal septicæmia in rabbits and dogs (but *without* the occurrence of pneumonia) by injecting them subcutaneously. The same result followed the injection of sputum, blood, etc.

"Matrey and P. Seifert, 1882–83, found the 'characteristic cocci' in the sputum; *i.e.*, diplococci, but they think them pathognomonic.

"Strassman, 1883, found the same cocci in the mouth in health.

"Friedländer, 1883, described more closely the 'gelatinous envelope' previously discovered by Günther. He considered it characteristic of the coccus. He was able to produce typical lobar pneumonia in mice by the inhalation method.

"Emmerich and Fränkel inoculated mice with positive results. Rabbits suffered from fever for a day or two, but recovered. Fränkel does not consider the capsule characteristic.

"Platonow, 1885, has found capsulated cocci in sputum of many cases not pneumonic, and does not think that the examination of the sputum is of any value clinically. Injections subcutaneous in mice caused death without pneumonia.

"Inoculations upon animals are sometimes followed by septicæmia with pneumonia; sometimes by septicæmia without pneumonia. It may still be regarded as an open question whether the so-called 'pneumonia coccus' is the cause of the disease, or whether it only finds in pneumonic lungs a favorable soil for its development.

"In an article in the July number of the *American Journal of the Medical Sciences*, Sternberg shows, by carefully conducted experiments, that the pneumonia coccus of Friedländer is commonly found in normal human saliva. He shows also, what other experimenters have shown, that it is a pathogenic organism so far as certain lower animals are concerned, and that its pathogenic power varies under different circumstances. He concludes that it is extremely probable that it is concerned in the etiology of croupous pneumonia.

"If, however, the pneumonia coccus is one that we carry with us always in our buccal secretions, and so many of us happily with impunity, it looks as if we would have to invoke some other cause to explain its occasional virulence. This the bacteriologist is always prepared to do. The production of a proper soil is the only thing necessary to determine the auto-inoculation which produces the disease. This soil, they say, may be prepared by any of the depressing influences that belong to our environment or are begotten of our vices. This theory, of course, is capable of infinite expansion, and would solve many mysteries, if it were not that as physicians we are better prepared than most men to appreciate the wisdom of Mr. Billings' remark that 'there are so many things asserted in this world that ain't so.'"

Dr. William H. Thomson said that the present time he was very much in harmony with Dr. Draper in one respect, and that was he did not know what to believe; and Dr. Draper certainly had not helped him out of that uncomfortable condition of mind. He was, however, inclined, more than twenty years ago, to believe that this disease is a specific fever. Two illustrations would suffice to afford some grounds for inferring that, in some cases, this is the character of the disease.

In children we have frequently a pulmonary affection which is characterized by a local disease, and occasioned by local causes, namely, broncho-pneumonia.

But now and then we see typical cases of croupous pneumonia, the cause of which is in marked contrast with the ordinary pneumonia of children, and which has given color at least to the belief that the disease in these cases is of an infective nature. The disease is ushered in by an evident shock, the patient presents all the appearances of having a rigor, to be followed by severe and prolonged delirium, accompanied by a high range of temperature, developed suddenly. No pneumonic process whatever can be detected for thirty hours perhaps, and afterward the pneumonia follows the ordinary course and terminates with sudden crisis. It is difficult to suppose, in these instances, that the disease is the same as that which occurs with bronchitis; but instead the entire clinical peculiarities in such cases point toward a specific fever, if there is anything which points to a specific well-marked infection.

The other illustration is from cases in which ulceration, endocarditis, and pneumonia occur simultaneously with meningitis, dependent upon true infection. Where we find an inflammation developed under such circumstances, and running exactly the course of pneumonia, and originating from a single focus of infection, it is easy to demonstrate the infective character of the affection.

Dr. A. Jacobi said that pneumonia meant an exudation into the open spaces and into the tissue of the lung, after an incipient stage of hyperæmia. In some cases the exudation into the air-cells consisted of albuminous matter, with a large number of lucocytes, more or less fibrin, now and then a few red blood-corpuscles, and some mucus.

In other cases there was less albuminous matter, more mucus, etc., but the process was about the same. The first was called croupous, the second broncho-pneumonia. The difference, anatomically, was very slight. Thus we had been wrong in discriminating too strongly between the croupous and the broncho-pneumonic process. So far as the coccus was concerned, Dr. Prudden had demonstrated that Friedländer's micro-organism is found not only in croupous but in broncho-pneumonia as a rule, which shows that the species belong to the same class. Dr. Jacobi would deny *in toto* that pneumonia must necessarily be a bacteric process. The question was not at all whether or not it was a fever produced by bacteria or some other poison. The question is not, is it a fever? The question is, may it be a fever? He would answer, yes. There were a large number of infective cases, and some of them were bacteric in origin. As illustrated by Dr. Thomson, the pneumonia occurring with ulcerative endocarditis might be bacteric and embolic at the same time, and at other times it was not of that character.

Dr. Kinnicutt said, even if Friedländer's differentiation of a specific micro-organism in *primary lobar pneumonia* should be shown to be incorrect, we were now in possession of a large number of careful observations, by competent physicians, demonstrative of the existence of such a disease as *epidemic* and *apparently contagious pneumonia*. One of many instructive accounts of such an epidemic had been given by Surgeon-Major Costello, of the Bengal medical service. "Thirty to forty fatal cases of primary pneumonia occurred in his regiment of five hundred and fifty men in the course of a few weeks. When it occurred among married men, it spread to the different members of their families; when treated in hospital, it spread to other patients ill of other diseases, and to the nurses. Removal from barracks to tents, and careful isolation of affected persons and their attendants, immediately arrested the progress of the epidemic."

In support of Friedländer's micrococcus, Dr. Kinnicutt would remind the members of the Section of the discovery of Dr. Emmerich, of Munich, who demonstrated that "the material used as stuffing between the ceiling and the floor of a jail, where epidemic pneumonia had long prevailed, contained numberless micrococci identical with those described by Friedländer." In the presence of many trustworthy reports of the occurrence of epidemic pneumonia, we at least must recognize the existence of a *contagium*, even if we do not accept Friedländer's discovery as final, in the etiology of a *certain number* of cases of pneumonia.

It seemed to him, therefore, that only two views of the nature of primary pneumonia were tenable. The one, advocated by many authorities, that in all probability there were two forms of the disease: one arising from cold or a like cause, the other zymotic; that these two forms were at present confused together, such as typhoid and typhus fevers had been in the past.

The other view maintained the *unity* of primary pneumonia and the constant presence of a specific morbific germ in its causation. As an individual opinion, based upon his own study of the disease, upon its many phenomena, Dr. Kinnicutt would say that the latter theory seemed to him the more tenable.

Dr. Delafield had listened with much pleasure to the remarks of the different gentlemen, because it seemed to him that they indicated a very decided change in the feeling of the profession, and a change in the right direction. It was only within a moderate length of time that certainly the fashionable belief was that lobar pneumonia was an infectious disease, that croupous pneumonia was always the same thing, and that catarrhal pneumonia was something different; that croupous pneumonia was the lesion of a general disease, and that catarrhal pneumonia was local inflammation. He thought the remarks made this evening had shown that if this belief had not been abandoned, it had at all events been shaken, and that the profession were beginning to appreciate that pneumonia was nothing but inflammation of the lungs, the modifications depending principally upon the age of the patient and the condition of the lung inflamed, and that like inflammation of any other part of the body might be produced by a great variety of causes.

Still further than this, the idea that typical lobar pneumonia is an essential fever he was glad to learn that Dr. Draper was no longer fully convinced of. For himself lobar pneumonia had always been a typical example of local inflammation, and not an infectious disease.

Dr. Jacobi thought the instances cited by Dr. Kinnicutt should not be taken as evidence of contagion, for he had, very many times, seen a large number of patients, particularly children in hospitals, taken at about the same time with pneumonia, because they were exposed to the same influences. Pneumonia was not contagious because ten or twenty cases developed in one locality at the same time, and he should say that the explanation of the occurrence of so many cases lay in the fact that the patients had been exposed to the same causes.

Collective investigation with reference to pneumonia, begun in this country in the Medical Society of the County of New York, had resulted in establishing the following facts, which were known to every one of us: Cold weather, wind, and moist atmosphere would give pneumonia. With a large rainfall, distributed over a large number of days in one month, especially when accompanied by cold weather and wind, pneumonia prevailed, it was called frequently an epidemic; but the frequency of the development of the disease was because a large number of people had been exposed to the same causes. Jürgensen and Koeller had said that pneumonia occurred principally in dry weather. Why? Because micrococci are in the soil, and pneumonia is a bacteric disease, and when the soil gets dry the micrococci get loose and give rise to the disease. That was the style of reasoning of some men who were called up as reasoners in bacteriology, to prove the reverse of what our fathers knew, namely, that pneumonia occurs principally in cold, moist, windy weather, when the soil is not dry.

Dr. Draper said Dr. Kinnicutt's remarks with regard to epidemics observed by Emmerich recalled to his mind

some facts concerning the history of cerebro-spinal meningitis, which he had occasion to study at about the time he was studying the subject of pneumonia. He found in the literature of that subject the history of a number of epidemics of pneumonia, some of them in this country, all occurring under similar conditions, mentioned by Dr. Kinnicutt, in jails, camps, etc. As he had already stated, while he thought that epidemics of that kind went far to prove that pneumonia might be, under certain circumstances, an infectious disease, he also thought that they proved that only of the epidemics, and did not prove it of all cases of pneumonia.

Thus, cerebro-spinal fever produces sometimes extremely violent lesions, pulmonary, arthritic and meningeal, and all these lesions may occur in the same patient; the arthritic and the meningeal lesions frequently occur together. Whether cerebro-spinal meningitis is an infectious disease or not is still a mooted question, but circumstances seem to favor the view that it is a specific fever. He had, in conclusion, only to reiterate that it was impossible for us to decide the question, and that the limits of our knowledge at present compelled us, as Dr. Delafield had said, to regard pneumonia as an inflammatory disease, and beyond that we did not know. It was pleasant to speculate, perhaps profitable, but whether profitable or not, in view of present existing theories, could only be determined at some period in the future.

The Section then adjourned.

MEDICAL CHARITY AND THE CHARITY ORGANIZATION SOCIETY.

On Friday evening, November 20th, a large number of physicians and gentlemen who are connected with charitable medical institutions met at the hall of the Academy of Medicine, in answer to invitations issued by the Charity Organization Society, to consider measures for reducing, through co-operation with the Charity Organization Society, the existing abuses and misapplication of medical charity. The chairman of the meeting was John Harsleu Rhodes, a Director of the New York Eye and Ear Infirmary. Those who have been connected with charitable institutions for years in this city have noticed, he said, the great increase of paupers who applied for aid. By paupers he meant people who wanted for nothing what they were able to pay for. The question to be settled by the meeting was, how to remedy this abuse. The difficulty of separating the pauper from the poor man existed because the charitable medical institutions did not pull together. This difficulty, in a great measure, had been overcome by the formation of the Charity Organization Society.

Charles D. Kellogg, Secretary of the Charity Organization Society, explained its object and working. It was founded in 1882 for the purpose of increasing the efficiency of all charitable institutions and to elevate the condition of the poor. Such alliances exist in many European cities and in forty towns in this country. Its register shows the names of 98,000 families who have applied for relief since its organization. Cards are furnished by it to all charitable institutions. These in turn, if they return the cards with the names of those who apply to them for relief, are furnished with such information about the applicants as proves them to be worthy or unworthy of gratuitous relief. To show that much of the relief given is unworthily bestowed, Mr. Kellogg gave some statistics. Of 79 applications at one hospital in this city, 24 were able to pay for relief and 27 could not be found at the addresses given. At another time 400 applications were investigated. One-third of the number were unworthy, and one-third had given false addresses.

Dr. J. West Roosevelt offered the following resolutions favoring the use of the system of the Charity Organization Society by all the hospitals and dispensaries of the city:

"It is the sense of the representatives of the several hospitals and dispensaries of the city here assembled that steps should be promptly taken to reduce, and, if possible, prevent imposition upon medical charities and to insure that the contributions of the charitable are used only for the benefit of the destitute and not wasted upon persons who can and should pay a physician for his attendance.

"*Resolved*, That the best existing remedy lies in the use of the methods and system of the Charity Organization Society."

Mr. Kellogg stated that London and New York furnish medical aid to more than one-fourth of the inhabitants. Boston to a little less than one-fourth, and Philadelphia to one-fifth.

Dr. Roosevelt thought the provident dispensaries could not be made successful in this country. He thought that not more than 150,000 to 175,000 people received medical aid last year in this city.

Dr. Samuel Hall seconded Dr. Roosevelt's resolutions and made some remarks to show the advantage of charging a small fee for medicines. This sum would be saved from drink and be a direct gain. He said that the Northern Dispensary treats but two-thirds of the number of patients it did ten years ago and does much more good.

Dr. Walter L. Carr spoke of the increase of the pauper classes by immigration. He mentioned the college clinics as asking for patients, and suggested that some arrangement be made by which the dispensaries could supply the needed material so as to prevent the present abuse. The Charity Organization Society, he thought should have control of the dispensary districts, and new institutions should not be started unless the Society sees some need for them.

Dr. S. O. Vander Poel said that doctors give one-third of their time to charitable work. The young physicians are indirectly the cause of the trouble, as they are anxious for the dispensary practice. He then read a letter from Dr. T. T. Gaunt, of the New York Dispensary, showing investigation of 845 patients by the Society for Improving the Condition of the Poor. Of these cases 504 were deserving, 235 were not, 38 were doubtful, and 68 were not found. Dr. Vander Poel proposed that a committee of representatives from some of the best-known institutions be appointed to confer with the Charity Organization Society.

Dr. Newman thought that Dr. Vander Poel's committee would be partial, and said that medical men should be added.

Dr. A. Siebert spoke of the work done by the Organization Society at the German Dispensary. Of 434 investigated, 107 gave wrong addresses; 187 were fully able to pay; 42 able to pay small fees; 75 unable to pay; 23 no answer.

Dr. Mary Putnam-Jacobi said that it is hard to decide what is the proper income by which to regulate whether a man shall apply to a dispensary or not.

Dr. A. Jacobi thought that dispensaries could help the poor by aiding them to bridge over the first years of their poverty, then when they get better positions they can pay family doctors.

Mr. McNeil, of the Northwestern Dispensary, spoke against the Charity Organization Society. He said that people should be glad to be cheated once in a while when doing a charitable act.

After some discussion, in which a number took part, the following gentlemen were appointed by the Chairman to confer with all the medical charities of the city and the Charity Organization Society, with power to call another meeting: Mr. Hewlett Scudder, Demilt Dispensary; A. B. Ansbacher, Mt. Sinai Hospital, and Drs. S. O. Vander Poel, J. W. Roosevelt, and J. H. Emerson. The Chairman was added to this committee by popular vote.

Among those present besides the gentlemen who took part in the discussion, were Drs. C. R. Agnew, R. H. Derby, Robert F. Weir, F. R. Sturgis, S. D. Powell, H. J. Garrigues, D. Webster, and Charles E. Young.

DIPTHERIA AND ITS MANAGEMENT.[1]

ARE MEMBRANOUS CROUP AND DIPHTHERIA DISTINCT DISEASES?

BY JOSEPH E. WINTERS, M.D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN, UNIVERSITY OF THE CITY OF NEW YORK.

SOME apology is needed for presuming to bring before this Section a paper on the treatment of diphtheria, when it has been discussed here so recently; my apology is that, notwithstanding all the ability which has been devoted to it, diphtheria still remains the most defiant of the so-called zymotic diseases.

Before discussing the management of diphtheria let us understand what the term includes. Does it comprise all cases of membranous croup? Are croup and diphtheria identical diseases?

The word croup, or croops, was first used by the peasantry of Scotland to designate a series of phenomena due to obstruction in the windpipe. This appellation was introduced into medical literature by Dr. Patrick Blair in 1718, thus: "The tussis convulsiva, or chink-cough, is also some years epidemical, and becomes universal among children, as is a certain distemper with us called the croops. . . . This convulsion of the larynx, as it begins, so it continues, so violently, that unless the child be relieved in a few hours, 'tis carried off within twenty four or forty-eight hours."[2]

The word does not seem to have taken root in the medical mind, however, for it was not generally adopted until 1765, when a monograph by Dr. Francis Home appeared, entitled "An Inquiry into the Nature, Cause, and Cure of the Croup," which attracted universal attention. Dr. Home believed croup to be an independent disease, due to exposure to cold. In 1771 Dr. Samuel Bard, of New York, in a careful monograph, pointed out the fact that the croup of Home was but a complication, or a form of the "angina suffocativa." In this classical treatise Bard clearly proves that the "sore throat distemper," or contagious sore throat, then epidemic in New York, was identical with the croup of Home. After Bard, Ruppius, of Baden, and Bretonneau, of Tours, wrote to the same effect, but Bard's treatise antedated theirs by nearly half a century, and to him alone is due the honor of showing distinctly that croup is not an idiopathic disease arising from cold.

Although Bard's investigations were made in New York, and his work is in the possession of the Academy of Medicine, where it may be consulted by any one, most physicians of this city maintain that membranous croup and diphtheria are distinct diseases; and that while membranous laryngitis does occur as a complication of diphtheria, it may also occur independently of the latter, arising solely from exposure to cold and wet. This is not only maintained, but it is taught in the several medical schools of this city.

Dr. Jacobi is the only physician I know in New York who believes that diphtheria and croup are identical.

The reasons assigned for regarding these diseases as distinct from each other are, that pseudo membranous croup occurs sporadically without the presence of diphtheria, arising simply from exposure to cold. But diphtheria occurs sporadically, and sporadic diphtheria may primarily attack the larynx.

The existence of a pseudo membrane in the lower part of the larynx and in the trachea is no evidence of the non-diphtheritic origin of the exudate. Neither the extent nor the histological structure of the false membrane affords ground for a distinction between these two affections. Morbid specimens from cases termed croup and from cases of diphtheritic laryngitis cannot be differentiated by the pathological anatomist.

Sporadic pseudo-membranous laryngitis has been known to convey diphtheria in its most pronounced form. Again, a mild case of diphtheria may give rise to no symptoms to attract attention to the existence of the malady until the complication of croup obtrudes it on the attention of the parents or nurse; and in the event of such a case proving fatal, pseudo-membrane in the larynx may be the only lesion of a diphtheria which primarily involved the tonsils and pharynx, where all evidence of the disease has disappeared during, and subsequent to, its spread downward.

The occurrence of marked paralysis, after so mild an attack of diphtheria as to be almost overlooked, is sufficient evidence that the cases of membranous croup which are said not to have been preceded by diphtheria, may have been diphtheria of an equally mild type, in which croup was the first symptom to attract attention.

Croup is claimed to be a sporadic, diphtheria an epidemic disease. Dr. Blair, who first described croup, speaks of it as an *epidemical* disease, and as one which sometimes becomes *universal* among children. From the time of Home to this date, numerous writers have recorded epidemics of membranous croup. The following authors describe it as a disease *distinct* from diphtheria, although they have met with croup in epidemic form; for instance, Churchill says: "It sweeps over a family, leaving behind it distress and desolation."[1] Tanner says: "Occasionally it appears to prevail as an epidemic."[2]

"As it (croup) may from these causes be endemic in particular situations, so, from the prevalence of cold east winds, particularly after damp relaxing weather, it may be epidemic at particular seasons."[3]

"Temperature, together with some endemic or *epidemic influence*, has to be admitted."[4]

It is maintained that croup is not contagious, while diphtheria is.

Cases have been reported where membranous croup having attacked one in a family, other members of the same family have suffered immediately from diphtheria of the tonsils and pharynx (Ranke, Wilks, Woodman).[5]

A young girl who had not been exposed to the same atmospheric influence as her sister, already ill with croup, was attacked by it after having been playing with her at the same time when her disease was completely developed."[6]

Gregory says: "I feel myself bound to act upon the

principle that croup in its worst, or most malignant form, is capable of being communicated by contagion." [1]

Copeland says: "Several authors have adduced facts to show that the disease may occasionally prove infectious. . . . It has most indubitably manifested this property when it has prevailed epidemically. . . . When croup occurs in one child of a family residing in situations where it prevails, more will probably be attacked." [2]

"Some practitioners have supposed the disease (croup) to be contagious because, forsooth, two or three children in the same family have fallen victims to it within a few days. They have overlooked the fact that in such cases all the children had been exposed to the same exciting cause, viz., a damp and cold state of the atmosphere." [3]

The croup of Dr. Hamilton, as described in his work, is, if studied in our modern light on the subject of diphtheria and croup, clearly nothing else than diphtheritic croup.

Cheyne [4] says: "I have no reason to think that croup is a contagious disease. Some winters since, within ten days, I attended two children in the same house, laboring under the second stage of croup; but both had been exposed. . . . When a physician has to visit more children than one with a croupy affection, in a family or neighborhood, he ought carefully to examine the state of the fauces."

Certainly one could make no other version of *such* cases of croup, except that of diphtheritic laryngitis.

Home, the historian of croup, seems to have met with a contagious form of the distemper, as he terms it, in Cases 4 and 5. These were brother and sister, the latter being attacked with the disease six days after the former, in both of whom it proved fatal. Home's symptomatology and dissection appearances in these cases make them undoubtedly cases of diphtheria with laryngeal complications.

Diphtheritic laryngitis is much less contagious than tonsillar and pharyngeal diphtheria, as it is evident that it would be, owing to the seat of the disease, but the contagious property in the cases of so-called non-diphtheritic croup has been as marked as we ever note it in diphtheritic laryngitis. *It is certain that an idiopathic laryngitis arising from cold could no more be contagious than bronchitis from the same cause.* The lymphatics are said not to be enlarged in croup, while they are so in diphtheria. The fact is, that in membranous laryngitis the cervical lymphatics may be involved, while glandular enlargement is not a necessary attendant on diphtheria. Swelling of the cervical lymphatics in laryngeal disease does not depend upon the character of the affection, but rather upon the amount of disease in adjacent structures, as shown by the absence of lymphatic involvement in malignant disease strictly limited to the larynx.

The condition of the lymphatic glands is no criterion of the nature of the laryngeal affection. So albuminuria may be present or absent in either. It is held that croup is a sthenic, diphtheria an asthenic, disease. Croup may be, and oftener is, an asthenic, while diphtheria may be sthenic, depending upon the condition of the subject attacked and the character of the epidemic.

Sthenic and asthenic diphtheria have been seen in the same house, the former in a robust German child, the latter in a delicate, sickly child. The degree of febrile and circulatory reaction may be mild or severe in either croup or diphtheria, and is not of the slightest diagnostic value.

Paralysis and other sequelæ remain long after the local symptoms have disappeared in diphtheria, while it is said that croup has no sequelæ following in its train. Paralysis after diphtheria is not often met with, and recovery from diphtheritic laryngitis is very rare; hence paralysis as a sequela of diphtheritic membranous laryngitis must be a rare event. Yet cases of paralysis following "membranous croup" have been reported. In fact, everything that has been written by those who have contended that membranous croup is an independent disease, distinct from diphtheria, is merely a compromise, and does not give one tenable diagnostic characteristic between them.

Many of the cases of croup recorded by various authors, and many of the descriptions in the text-books are, in the light of present pathology, clearly cases of diphtheria.

Case 5 (p. 17), of Dr. Francis Home,[1] was certainly one of diphtheria, probably contracted by contagion from Case 4 (p. 14), the brother of Case 5. Case 7, as related, presents to us the usual course of diphtheria, with laryngeal complications; the boy being allowed to walk about, and consequently exposed to cold, a reaccession of the symptoms occurred. Treatment apparently controlled the disease again, when there was a second exacerbation, during which the child died of croup. As is *usual* in such cases, the diphtheritic inflammation *then* involved the larynx only.

Home says himself of this case, "I suspected that there was considerable mixture of the angina with the croup here." On page 36, in his conclusions, Home says (Corollary iii.): "In some of the former cases the whole glands, at the root of the tongue, and the *amygdalæ* were turgid, and the parts covered with mucus." Again he says (p. 51): "This disease appears, in general, to be a very dangerous one, and the more so as it is silent in its progress, and gives no visible alarm till death is near at hand. The first stage of this distemper often passes unobserved, and before we see it, is beyond all remedy." This is exactly the experience which we too often have with diphtheria now in New York.

Bard [2] in his monograph says what any intelligent observer would say after a careful analytical study of Home's *croup*, p. 14: "Such a remarkable agreement in the symptoms is of itself almost sufficient to determine these diseases to be the same, but when we compare the appearances from dissection, it is placed beyond a doubt."

Dr. Austin Flint, in his article on Diphtheria, says: "Regarded from a clinical point of view, it seems to me clear that this question (Are diphtheria and croup distinct diseases?) is to be answered in the affirmative" (Flint's Practice, 1881, p. 1082). In his article on Croup (op. cit., p. 295) he says: "The exudation, in the form of a false membrane, is found in the larynx and trachea; it is also present, as a rule, in the pharynx, on the tonsils, *soft palate*, base of the tongue, or epiglottis. . . . The larynx may be primarily affected, or the false membrane may appear first in either the pharynx or the trachea; the point of departure of the inflammation and exudation being in some cases the larynx, and in other cases the pharynx, oftener the latter" (p. 298). Unmistakably this description can apply to nothing else than diphtheria.

In former diphtheria epidemics it appears, from the descriptions handed down, that diphtheritic laryngitis must have frequently occurred independently of any membranous affection of the throat above, and even now in some places, according to the evidence of many good observers, it is occasionally met with, but at the present time it certainly occurs almost exclusively with diphtheria of the throat.

I have never seen a case of membranous laryngitis of non-diphtheritic origin, although I have been called in consultation to many cases of so-called croup. Nor have I met with a case in which there was a membranous ex-

udate in the larynx, but that there was some evidence of a diphtheritic process in the parts above, either preceding or subsequent to the laryngeal affection. Even in cases where no patches of membrane were discovered in the fauces during life, patches of exudation were found about the posterior nares or at the root of the tongue after death.

Sudden vicissitudes of atmospheric temperature, especially in combination with rain, constitute the principal cause of croup, according to those who claim that croup is an independent disease. Nothing is more common than catarrhal laryngitis with croupy symptoms in a young child at the same time, what would be more phenominal in the varied experience of a physician than for such a case to terminate in pseudo-membranous laryngitis? This catarrhal croup may last several days, and it may become chronic, but has it *ever* been seen to terminate in membranous croup?

I have had three such chronic cases within the last four years. One died since of pneumonia; I found at the post-mortem examination congestion and thickening of the mucous membrane lining the larynx, and infiltration into the submucous tissue of the subglottic region, with subchordal swelling, but there was no pseudo-membrane. This child had had a croupy cough with paroxysms of dyspnœa for twenty months previous to its death. The other two are living, and apparently quite comfortable, with the exception of a most distressing croupy cough and dyspnœa when excited, or when there is a sudden change of atmospheric temperature. We have all met with instances where a young child, after coming out of its bath, having been allowed to be about naked and exposed, has an attack of catarrhal croup, which, in the severity of its symptoms, has apparently placed life in immediate jeopardy, yet such cases *never* terminate in membranous laryngitis. If a child already ill with diphtheria should suffer the same exposure, the catarrhal laryngitis will rarely fail to invite the diphtheritic inflammation to the larynx, and induce the formation of a pseudo-membrane. Though membranous laryngitis occurs in diphtheria in adults, who has seen even the oft-repeated attack of severe laryngitis in the adult terminate in the membranous form, which it surely would if one were merely a higher degree of the other, no special cause or element being necessary?

We frequently meet with cases of loss of voice in the adult after exposure to cold, which lasts many days without causing any inconvenience, passing off without treatment, and never attended with the discharge of false membrane. Nor does the more acute laryngitis, with high fever and symptoms dangerous to life, produce the membranous exudate which so quickly results when diphtheritic inflammation attacks this organ. The simple laryngitis of both adults and children may exist for months, even almost indefinitely, without showing any disposition to extend into the deeper air-passages; but diphtheritic laryngitis manifests this tendency very quickly, and always early involves the trachea and bronchi. Dr. Geo. Johnson says:[1] "For myself I may say that, having diligently worked with the laryngoscope for twelve years, I have never seen croup with a membranous exudation in the larynx which was not the result of diphtheria." The laryngoscopic investigations of Dr. C. Rauchfuss and Dr. Karl Dehio in the laryngeal affections of children have made clear many forms of acute laryngitis in them hitherto obscure. First Rauchfuss, and after him Dehio more fully, showed, that in acute laryngitis with œdematous infiltration of the submucous tissue below the vocal cords, especially where the cords are inflamed and swollen, there is laryngeal stenosis, with the same cough, dyspnœa, and loss of voice that we have from membranous obstruction at the rima glottidis; symptoms which we have been accustomed heretofore to refer to pseudo-membranous laryngitis. In acute diffuse laryngitis, with subchordal œdema, we may have all the symptoms of membranous laryngitis, except the laryngoscopic and post-mortem appearances.

These facts, their recent discovery, and the statement of Dr. Johnson, make it not only probable, but altogether presumable, that some of the cases of so-called membranous croup of non-diphtheritic origin were cases of acute subchordal swelling with stenosis. While it is conceivable that pseudo-membranous laryngitis may occur idiopathically from exposure, we feel justified in the conclusion that, after careful clinical and pathological studies, no one has yet proved that such is the case.

Again, if membranous laryngitis, as the outcome of cold, does occur, it cannot be differentiated clinically or pathologically from diphtheritic croup.

The committee appointed by the Royal Medico-Chirurgical Society in 1879 to make investigations as to the identity of croup and diphtheria, state that[1] "notwithstanding urgent and repeated public appeals, no single case of membranous exudation in the larynx resulting from exposure to cold has been furnished to the committee."

Quite recently I have found evidence, striking enough in itself, of men like Sir Thomas Watson, Sir Wm. Jenner, Dr. Charles West, and others of equally high repute, who at one time maintained that croup and diphtheria were distinct diseases, but now express their opinions to the contrary. Sir Thomas Watson in his article on Diphtheria, says:[2] "Some analogy to this disease (croup) it certainly has, but the points of difference are stronger and more essential."

"We are now prepared for the consideration of a most important question. Is the disease, which has for so many years been called in this country the croup, and which is attended with a membranous exudation in the larynx, anything else than diphtheria? I believe it is not. I believe, with Dr. Johnson, that ever since Dr. Home's pamphlet on 'Croup' was published, in 1765, our writers on the subject have given us the history, the symptoms, and the treatment of acute catarrhal laryngitis, with the morbid anatomy of diphtheria."[3]

"Are diphtheria and croup essentially the same disease? I think not."[4]

"My opinion has undergone some modifications, and I am inclined now to the belief that there is no such disease as idiopathic, simple, membranous inflammation of the larynx. I say I am inclined to the belief. I am not sure that this is true, but as I formerly thought that the weight of evidence was in favor of their non-identity, I am now inclined, from my further experience, to think that the two diseases are really identical, that the so-called croup is really diphtheria."[5]

"There are, indeed, two diseases which have often been included under the common name of croup, though the points of difference between them are at least as numerous and as important as are those in which they resemble each other.

"If we extend our inquiry beyond the mere changes wrought in the respiratory organs, the differences between croup and diphtheria at once become apparent. Different, however, as these two diseases are, there are yet between them points of similarity no less striking (p. 323)."[6]

"For all practical purposes membranous laryngitis or membranous croup must be regarded as the outcome of diphtheria, and consequently as essentially different from catarrhal croup or catarrhal laryngitis.[7] . . . Diph-

theria, then, is the disease, croup but one of its symptoms.

"I have been well-nigh fifty years in coming to this conclusion. I do not know that my confession of faith loses in value because I have been a tardy convert tomy creed."

Although cold has been regarded as the principal etiological factor of croup, since the time of Home, it is clear to us that it cannot give rise to a membranous exudate in the larynx, except with the presence of the diphtheritic poison.

If membranous croup, then, is only a complication of diphtheria, is it the natural tendency of diphtheria to propagate itself into the larynx, or is this an accident of the disease, which, with due precaution, can be evaded?

We have the question, then. What relation does cold bear to croup as a complication of diphtheria? We all know that a catarrhal state of the mucous surface of the pharynx and larynx favors and hastens the spread of the diphtheritic inflammation. Catarrh, therefore, becomes the great predisponent of diphtheritic laryngitis, and exposure induces catarrhal inflammation the more readily in a child depressed by diphtheria.

When diphtheria occurs in a child recovering from, or who has recently had severe measles, there is a special tendency to laryngeal complications. Scrofula, rachitis, etc., with catarrh of the mucous tracts, also make us especially apprehensive of this accidental danger.

In corroboration of the view that cold and catarrhal inflammation predispose to,[1] and even directly cause, the spread of the diphtheritic process into the larynx, we see that croup complicates diphtheria more in autumn, winter, and spring, than in the summer; that it occurs especially after sudden vicissitudes of temperature and rainfall, in connection with, or soon after, prevailing east or northeast winds,[2] more in boys, who are more exposed, than in girls,[3] and that it is more prevalent in rural than in urban districts.[4]

Pseudo-membranous laryngitis is a more frequent complication in sporadic diphtheria than it is when the malady is epidemic. I assume the explanation of this to be the greater care taken at the time of an epidemic, the nature of a larger proportion of the cases being earlier recognized, and the patients being more likely to be confined to bed, thus removing the accidental element in the causation of this complication. The greater hardihood of boys and their unwillingness to complain, and their consequent exposure, is, I believe, the reason of the greater frequency of diphtheritic croup in them.

In country districts where less is known by the people about diphtheria, where the more robust children give less heed to its first symptoms, and where, in consequence, a physician is not so early summoned, *croup* is more common than in the city, where it (membranous croup) is scarcely ever heard of except among the very poor, but as a complication of a previously recognized diphtheria.

We have all seen exacerbations of diphtheria from cold. A patient allowed to go about during convalescence suddenly has an augmentation of all the symptoms; this is the more likely to occur if there is a sudden fall of temperature, but even in the absence of this, exhaustion of the patient's powers causes a relapse, and a spread of the inflammation. Not unfrequently such a relapse proves more severe than the first attack, and if there has been marked exposure, the disease for the first time shows a disposition to, and does extend into, the larynx.

It is not the cases in which ulceration and sloughing of the throat occur from the very commencement (a circumstance which indicates a more intense form of the disease), that the larynx is most frequently involved, but rather in the so-called mild types of the disease, in which the patient, not being considered very ill, is allowed to expose himself, and exhaust his strength; both the exposure and the exhaustion promoting the extension of the morbid process. Although croup may be an unavoidable complication in some cases of diphtheria, my experience forces upon me the conviction, that it occurs for the most part in cases where there has been exposure and undue exhaustion, which would tend to show that croup is not so much a necessary consequence of diphtheria as its frequency would seem to impart. It follows, logically, that by judicious management, we can, in many cases, prevent this complication. To manage patients with diphtheria, so as to prevent the occurrence of croup, would be casting an anchor of safety in a large proportion of the now fatal cases. It may seem unnecessary to urge the importance of keeping patients with diphtheria in bed, but I know that it is common in the practice of many physicians to allow patients with extensive exudation to go about the house; and in many of the mild cases the patient is not confined to bed throughout the entire period of the disease. Although physicians do not often relate or record cases exemplifying this negligence, yet such cases are recorded, and they show distinctly that between cold and croup as a complication of diphtheria, there is the relation of cause and effect.

In the *British Medical Journal*, June 25, 1849, p. 498, it is stated that "Case 45 died of laryngitis, from imprudent exposure during recovery from diphtheria." By turning to the record of the case, we find that the girl got up and went out of doors while making favorable progress toward recovery.

Another case is found in the "Transactions of the Medical Society of Pennsylvania," for 1879, p. 888, by Dr. G. A. Linn, in the following words: "An older child (three years) seemed to be doing well on the treatment, when, from exposure to wet, during the funeral of the other, he grew suddenly worse, the membrane formed in the windpipe, and he died from obstruction." This instance is often repeated in the tenement-houses in New York.

In the *British Medical Journal*, July 4, 1863, p. 4, in connection with Case 7, it is stated that "the throat having cleared off, pain in swallowing increased. He could be persuaded to swallow only milk, and very reluctantly gargled or permitted any cleansing of the throat. Still he held his ground for a fortnight; was able to walk about his room and went for a drive, so that we hoped he would gradually get better. There was no indication of affection of the lungs or trachea, till one night he was attacked with cough, bloody expectoration, and dyspnœa, with râles all over the chest. In the fluid expectorated we found some branching strings of tenacious mottled substance, which were evidently casts, in lymph of the air-tubes. He could not swallow anything, and rapidly sank and died in the middle of the next day."

Squire[1] says: "A child has been taken out for a walk on the fifth day with a temperature *in recto* of 103.7° F.,"

[1] "The majority of cases occurred in winter and spring; in other words, at a time when catarrhal disorders are of most frequent occurrence" (A System of Practical Medicine. By American Authors. P. 682. Philadelphia, 1885).

[2] "It is generally believed that, according to observations the larynx and air-tubes are far more frequently affected with the disease in the cold and dampness of winter than in the warm summer months" (Ziemssen, vol. i., pp. 583, 584).

"The statistics of Wibmer show a greater prevalence of the disease during the winter, especially from September to December, which period had afforded an especially high mortality in diphtheria, in comparison with the months from April to August, when the mortality from diphtheria was at its minimum, 1864–69" (Ziemssen, vol. i., p. 583).

"Variable climates and cold wet weather favor the onset of laryngeal symptoms" (Royal Medico-Ch. Tr., 1879, vol. xxii., p. 10).

"It (croup) has been found to be most prevalent during moist, cold, changeable weather, and in many cases the attack seems to be immediately due to exposure to sudden changes of temperature or to cutting north and northeast winds" (Steiner in Ziemssen, vol. iv., pp. 236, 237).

"Out of 467 epidemics of croup, collected by A. Hirsch, 159 belonged to winter (December, 56; January, 48; February, 33); 130 to spring (March, 51; April, 42; May, 37); 72 to summer (June, 21; July, 23; August 38); and 106 to autumn (September, 22; October, 41; November, 42)" (Steiner, in Ziemssen, vol. iv., p. 237).

"The deleterious influence of moisture is shown by Crawford's observation, that in Scotland croup, which had hitherto been a common disease, became rarer after the drying of marshy districts" (Ibid., p. 237).

[3] "The male sex is more frequently affected than the female; in my own cases, out of 101 children, 77 were boys and only 24 girls. In Bohn's 70 cases, 43 were boys and 27 girls. Ruehle gives the proportion of boys to girls as 3 to 2" (Steiner, in Ziemssen, vol. iv., p. 235).

[4] "There is ground for the belief that that form of the disease which issues in membranous laryngitis is less common in cities than in damp or bleak country districts, or in exposed situations on hill-sides, and thus probably because such localities are favorable to the occurrence of catarrhal ailments" (West, 7th ed., 1884, p. 415).

[1] Op. cit., p. 121.

and "a young man was found dressed and walking about on the ninth day of illness, with a surface temperature of 102° F. On being kept in bed the temperature fell two degrees in two days; the exudation then ceased to extend."

"The peculiar features by which the eye of experience already recognizes a great and closely impending danger while the unbroken spirit of childhood is yet scarcely checked in its playfulness."[1]

Mackenzie[2] says: "Whenever there are signs of approaching cardiac failure, it is important to keep the patient in bed with his head low, and to interdict any movement whatever."

These quotations, from such wide sources, show that there is not the importance attached to prevention of exposure, to absolute rest, and to conservation of strength, which seem to be demanded in this malady. Frequently practitioners have said to me, "The child has not seemed to be very ill, and he has not been kept in bed, but the local process has steadily advanced."

In patients kept in bed there is rarely seen that extreme prostration so common in diphtheria, nor do we so frequently meet with the slow, feeble, and irregular or the very fast pulse. *If allowed to be up asthenia and the exudation advance together, the one increasing the other.*

Absolute rest in bed is demanded, then, in diphtheria, from the appearance of its first symptoms until convalescence is complete.

It preserves the failing strength, it lessens the spread of the exudation, it prevents exposure, and all these diminish the liability to laryngeal implication. With this management, if a child has been under observation and treatment for three or four days, and there is no involvement of the air-passages, it is not likely to occur, and the prognosis is good. Does cutaneous diphtheria, or diphtheria of an external wound, ever give rise to croup, without first appearing in the throat above the larynx? Although I have seen many cases of wound diphtheria, I have seen no tendency for it to give rise to croup without throat diphtheria.

Nasal diphtheria does not produce croup except by extension (see p. 626). While croup does not occur as a complication of wound diphtheria without having first involved the throat above, paralysis occurs as a sequela of cutaneous, wound, and nasal diphtheria, without the disease having appeared in its most usual site—the throat.

All the cases which have come under my care testify to the correctness of this view, that croup as a complication of diphtheria is usually accidental.

The treatment of diphtheria is far from having reached that unity which might have been expected from the attention which has been devoted to its consideration. The number of remedies to which physicians are continually having recourse proves the inefficacy of the greater number of them. Some remedies which have recently been highly recommended, if used as unsparingly as their advocates directed, would certainly be injurious, while others have been tried and proved to be useless. If we study the death-rate of this disease, we must confess that, up to the present time, we have not, on the whole, been very successful with any mode of treatment. It is easy to be deceived in regard to the usefulness of a remedy employed against diphtheria, for some cases will do well with very little treatment, provided they receive good care; on the other hand, where a case or a number of cases are not influenced, or at least not favorably affected by the treatment, we are too prone to tell the parents that it is a case of unusual virulency, or one of malignancy, instead of examining into our comprehension of the case, and our treatment of it, and admitting that the cause of failure to cure lay here. True, there are cases of diphtheria of great malignity, but if we were to adopt a system of rational therapeutics to meet the indications of each individual case, based on well-considered physiological and pathological data, we would hear less about malignant diphtheria.

We are too apt to be wedded to particular methods of treatment, and believe in their excellence, without giving due regard to the indications of cure furnished by the epidemic character of the disease, the constitution and diathesis of the patient, the character of the symptoms, the disordered functions of the important organs of secretion and excretion; the modes and paths of elimination of the virus of the disease; the disposition to certain complications; the prevalence of other epidemic diseases which might modify its course; and the season of the year Each and all of these conditions should be our chief guides, as in every case much depends on the precision with which the exact *nature* of the case, and the state of the vital powers are ascertained. The mode of treatment in vogue has for its object (according to its exponents) to attack the poison or germ of the disease, as an entity, and destroy it, leaving out of view every other consideration.

Physicians in search for such a specific are distracted from a rational treatment. These experiments have doubtless killed more patients than germs.

The enthusiasm with which all the mercurials are now recommended as a cure for diphtheria, would lead one to suppose that a true specific had at last been found—calomel, bichloride, biniodide, etc., internally, inunctions of mercury, and mercury by hypodermic injections. The calomel treatment introduced by Rush was used with considerable success by Bretonneau, Trousseau, Guersant, Blache, Bouchut, and many others, who derived much advantage from it; but they did not employ it indiscriminately, nor to the exclusion of other measures. In time, however, it came to be used to excess, and was finally abandoned as being injurious.

The distinguished Dr. Stokes said of it: "The mercurial treatment of croup is insufficient and unnecessary."

Dr. Rush used calomel as a derivative in croup, and this use of it unquestionably is serviceable if we do not use it to the degree of depressing our patient. He says:[1] "Its good effects seem to depend upon its exciting a counteraction in the whole intestinal canal, and thereby lessening the disposition of the tracheal blood-vessels to discharge the mucus or form the membranes which have been described." Recently this treatment has been revived, and there is evidence already that instead of using it with a cautious, discriminating judgment, it is being again abused.

We read of calomel being administered in forty-grain doses in serious cases of diphtheria, and one hundred grains in twenty-four hours.[2]

It almost constitutes malpractice to give such a dose to a young child depressed by the poison of diphtheria.

Again we are told:[3] "If ever mercury is expected to do any good in cases of suffocation by membrane, it must be made to act promptly. . . . I recommend the oleate, of which ten or twelve drops may be rubbed into the skin along the inside of the forearms or thighs every hour or two hours, . . . or hypodermic injections of corrosive sublimate in one-half or one per cent. solution in distilled water, four or five drops from four to six times a day or more, either by itself or in combination with the extensive use of the oleate, or with calomel internally." On p. 706 of the same it is said: "A baby a year old may take one-half grain (of corrosive sublimate) every day for many days in succession, with very little, if any, intestinal disorder, and with no stomatitis."

And in THE MEDICAL RECORD, May 24, 1884, p. 576: "I do also know that when the constitutional effect of mercury can be obtained speedily, cases of fibrinous tracheobronchitis get well in an unexpected manner. To ac-

complish that it is necessary to give small doses very frequently. Calomel gr. viij. to xij., divided into thirty or forty doses, of which one is taken every half hour, is apt to yield a constitutional effect very soon." He continues: "The actual benefit derived therefrom cannot have been very great, for the mortality from croup has nowhere been encouraging." Treatment short of blood-letting could not be more depressing than this. These enthusiasts need a little calm reflection to lessen their zeal.

The explanation of such wholesale use of mercury is that it is said to be an antifermentative or a germicide.

It is not worth while to reason against the fallacy of mercuric chloride being an antifermentative. When introduced into four pounds of blood, for example, in doses of one-fiftieth of a grain every two hours, providing all is absorbed, it is being constantly eliminated, or, if elimination is interrupted, it acts as an irritant to the alimentary canal, inducing purging or vomiting, often both at the same time. Recently it has been demonstrated by E. Klein and Blythe that corrosive sublimate possesses no more power as a germicide than pure water. Although prostration is one of the great dangers to be dreaded in diphtheria, and the testimony of physicians is a unit against the employment of depressants in the disease, mercury, a powerful depressant, is being used by many prominent physicians with as much fervor as they would use a known specific. Many infer, because salivation does not appear, that if the repeated small doses do no good, they can at least do no harm. Doubtless the fact that it is exceedingly difficult to excite salivation in a young child has led many to believe that mercury can be given to children of all ages in unlimited doses without causing harm. A. Jacobi says:[1] "A baby a year old may take one-half grain of corrosive sublimate every day for many days in succession, with very little, if any intestinal disorder, and with no stomatitis."

Although it does not cause either intestinal disturbance or stomatitis, it does produce great depression and debility.

"The fact that mercury may prostrate and destroy a young child, even though it does not cause salivation, it is to be feared is not sufficiently appreciated, at least by some."[2]

Mr. Colles, of Dublin, says:[3] "No man in the present day requires to be told that mercury never does produce ptyalism or swelling and ulceration of the gums in infants."

Dr. Evanson and Maunsell say:[4] "Mercury does not seem capable of salivating an infant. We have never seen it do so, nor are we aware of any such case being on record. . . . We have never succeeded in salivating a child under three years of age."

Dr. Warren, of Boston, observes:[5] "I have never known an infant to be salivated, notwithstanding I have given, in some instances, large quantities with this view."

Dr. Percival, of Manchester, remarks,[6] that he "repeatedly observed that very large quantities of the unguentum cœruleum may be used in infancy and childhood without affecting the gums, notwithstanding the predisposition to a flux of saliva at a period of life incident to dentition."

It is significant that where mercurial treatment has been pursued throughout in diphtheria, convalescence is always more tedious, and the anæmia of the disease is more persistent; and that where death occurs it is almost always from exhaustion. Even where the larynx has been implicated, the inevitable exhaustion resulting from the mercurial treatment hastens death, even if it has diminished the symptoms of obstruction.

Large doses of mercury, often repeated, powerfully depress the system of the adult, and naturally this depression is more profound in the child. This is shown by the fact that when ptyalism does occur in infants it is more disastrous in its effects on the delicate organism than on that of the adult. In the use of mercury with the small child great caution is necessary, as we have not the symptoms usually so readily induced in the adult, but which do not appear in the infant until so marked that they prove disastrous by throwing the child into excessive prostration, thus giving us a condition to treat quite as serious as the disease itself. I have seen several such cases, and I know that, as a result of the inconsiderate use of mercurials in the treatment of diphtheria, physicians are often called upon to treat the consequence of their want of caution; while they have blindly ascribed the rapidly progressive anæmia, prostration, marasmus and death to the disease alone.

I have seen, in consultation, several cases of diphtheria in which death resulted, and was to be imputed to, the excessive use of mercury rather than to the effects of the disease; yet the instructions I have just quoted had not in any instance been exceeded, nor even equalled.

Let those who believe in the vigorous use of mercury in the treatment of diphtheria read in volume ix. of the "Medico-Chirurg. Trans.," 1818, p. 220, and in Marshall Hall's "Principles of Medicine,"[1] how the illustrious Dr. T. Bateman fell a victim to mercurialization, the symptoms appearing on the ninth day of the mercurial inunction, one drachm of mercurial ointment, by friction, having been used every night.

The report of the Committee of the British Medical Association on the action of mercury on the biliary secretion was that it caused its diminution through its general depressing action on the entire organism. Recently it has been shown that mercury has a powerful destroying action upon the hæmocytes.[2] Yet this drug is now used as a curative agent in diphtheria, without any rational or philosophic explanation of its *modus operandi*.

Dr. F. R. Sturgis, who is an authority on this subject, says:[3] "The chlorides and the iodides are more apt to produce toxic symptoms than other forms." Notwithstanding this, these are the forms used in the treatment of diphtheria. When used with discretion, calomel is undoubtedly a valuable medicine in diphtheria. It probably acts as a derivative and eliminant by its purgative action, by its increasing the activity of many of the secreting and excreting glandular structures of the body, particularly the intestines, and it will be observed everywhere in the writings of the older physicians that calomel only did good in croup when it produced purging, and it stands to reason that in suitable cases occasional purgative doses may be beneficial, while to continue its use so as to induce its constitutional effect is injurious. Children suffering from diphtheria, who have had syphilis, are greatly benefited by the addition of a mercuric salt to the usual remedies found to be useful in diphtheria.

Children with scrofulous enlargement of the lymphatic glands, laboring under diphtheria, do better when a mercurial is judiciously added to the treatment. This is because both of these disorders are benefited by the careful use of mercury. But because such cases are found to do better where mercury is added to the treatment for diphtheria, to rush to the conclusion that all cases will be cured of diphtheria by it is a ridiculous fallacy. Neither bichloride of mercury nor any other mercurial being, in any sense of the word, a specific, and having no possible germicide or antifermentative action, the unsparing and injudicious administration of it,

without due comprehension of the indications furnished by the individual case, is only a blind and dangerous empiricism. I have unequivocal and direct evidence of the injurious effects of bichloride of mercury from two intelligent physicians who have had diphtheria, and who both experienced the depressing effects of the drug. They told me that they felt depressed as soon as the mercurial began to have an appreciable action on the intestinal tract, and that there was a feeling of nausea and sinking even preceding this. I may add, that after the discontinuance of the bichloride both patients felt within three hours the strengthening effect of the tincture of iron in full doses, given hourly. As no practitioner would persist in the use of bichloride or any other mercurial salt on himself or another physician after the depressing effect began to be felt, it should not be used thoughtlessly on children who cannot intelligently communicate their sensations, nor even on adults who would not be likely to notice the approaching depression and weakness as soon as a professional patient might, and so ward off a crisis.

That the mercurial treatment is insufficient to control the diphtheritic process is shown by a case recorded[1] of a girl, aged twelve, under treatment for pain and swelling of the joints (rheumatism), with calomel (among other drugs) until salivation occurred. While under this treatment the girl developed "croup," from which she died. Post-mortem examination revealed a layer of fibrine in the larynx, which was continued down the trachea and the lesser ramifications of the bronchial tubes. If it is true that mercurials cure croup, their action in this case should have prevented its development, in a patient under mercurial treatment, to its constitutional effect, when the disease attacked the system. Salivation, in fact, favors the extension of diphtheria; so the depression of the treatment promotes its spread when there is no local indication of its constitutional effect.

In diphtheria life is endangered by the great weakness induced by the malady itself, and I most seriously deprecate the employment of measures which depress the system, and especially of those by whose means we voluntarily bring on a secondary diseased condition, which may prove quite as dangerous as the original malady. These are sufficient reasons for the discontinuance of that free use of the mercurials, which is too often had recourse to without either thought or caution. The too universal extolment of them at the present time has caused an indiscriminate use of them, which brings harm to our patients, and will in the end cause the abandonment of a drug which is of undoubted utility if used as an auxiliary to our treatment, and will bring just opprobrium on our profession for using a remedy which has been over-zealously recommended on no sufficient foundation, and without any criterion to guide us.

At the present, more than at any other time, an accurate knowledge of remedies is obscured by false prophets, who cry, "A cure is found for diphtheria!"—thus setting a fashion, as it were, and the new idea is received and followed blindly.

If every practitioner would think for himself, weigh the results of experience, examine again and again old remedies and new applications of them, but at the same time be searching for new and more efficacious ones, it would be the means of our therapeutics growing in simplicity and precision.

In the absence of a specific for diphtheria we are reduced to the elimination of the poison of the disease; the counteraction, so far as possible, of its effects on the blood and system generally; to limiting the spread of the local morbid process, the prevention of complications, the amelioration of symptoms, the conservation and supporting of the forces of the system, the maintenance of nutrition, sustaining the heart, and, if need be, of stimulating into activity the latent vital forces. It is evident that no one remedy could meet these varied indications of cure; we must therefore depend wholly upon a judicious combination and sequence of means, adapted with judgment to particular cases. Can we eliminate the poison? Before answering this question, we must first know which are the natural channels of elimination of the specific poison of diphtheria? Without doubt these are the mucous membrane of the throat and air-passages, and probably by the intestines, kidneys, skin, and all the emunctories of the body. Prof. Loomis says:[1] "Clinical facts indicate that the infectious element is present in the exhalations and in the excretions, as well as in the exudation itself." Sir Wm. Jenner recommends that the treatment of diphtheria should begin with a purgative, believing that the elimination of the poison is thus made to take place by the intestinal canal.[2] I have noticed when the symptoms of diphtheria have been active from the outset, with considerable soreness of the throat, and with early and marked membranous formation, that if the patient has at once been placed in bed, diaphoresis induced, the bowels gently acted upon, the neck counter-irritated and poultices applied, there is a marked improvement; and that such cases, if judiciously managed, do well, and in nearly every instance make a good recovery; and presumably by rapid elimination of the poison. When, however, the outset of the disease is insidious, the process slow in developing, generally the treatment is less active, the poison is not so early nor so rapidly eliminated, the course is indolent with frequent relapses, and sequelæ are apt to remain.

From carefully weighing these facts, I have come to regard elimination of the poison as the first indication of cure in diphtheria. By this management we promote the expulsion of the morbific matter, and we are able to use, with decided benefit, drugs directed against the disease, such as iron, quinine, etc.; but the use of these drugs from the outset in cases of marked febrile disturbance, without preparatory treatment, seems to aggravate the symptoms and to less thoroughly control the disease. For the purpose of eliminating the poison so far as possible by the throat, intestines, skin, and kidneys, have recourse to mild purgation, simply sufficient to excite the activity of the glands of the intestinal tract, triturated calomel in small doses being the best for this; hot poultices to the neck to excite the activity of the mucous glands of the throat; powdered ipecacuanha co., as a sedative, diaphoretic, diuretic, or the hot foot-bath, according to indications. Of course this plan is not to be adopted indiscriminately, but our treatment must be modelled in accordance with the degree and acuteness of onset of the inflammation, and an accurate estimate of the vital individuality of the patient.

If we study the therapeutic indications from the standpoint of the lesions in the throat, the unaided reparative process of nature, the *modus operandi* of local treatment which may be adopted, and the effect of these on the morbid process, we are led to feel that we can control or at least modify the local manifestations of the disorder. Where several members of a family are successively attacked with diphtheria, and we daily examine the throat, thus inspecting it before the appearance of the exudate, we will observe its mucous membrane become reddened, its secretion diminish, and its surface dry. Besides these changes there is moderate swelling of a part of the mucous membrane, while the rest may appear normal. After the lapse of a few hours, small grayish- or yellowish-white specks appear. If the diphtheritic process progresses uninterruptedly, these spots of membrane coalesce and may more or less completely cover the inflamed surface.

The evidences of advancement of the process, and of its *diphtheritic character*, are to be found in the edges of the patches being thinner than the centre, and shading off imperceptibly into the inflamed mucous membrane,

[1] London Lancet, vol. i, p. 726, 1838–39.

[1] Practical Medicine, p. 672. Wm. Wood & Co., New York, 1884.
[2] W. H. Day: Diseases of Children, p. 351. Philadelphia, 1881.

in being surrounded by a zone of angry-looking inflammation, and in their appearing on the pillars of the fauces.

If now, a reparative process is established, the vascular injection at the immediate edges of the diphtheritic membrane lessens, the patches thicken at their edges, and separate, usually in small portions. This process of repair is due to the effusion of serum, the exudation of mucus, the immigration of pus-corpuscles, and the loosening of the pseudo-membrane by ulceration. The object of local treatment, then, must be to allay inflammation, to re-establish secretion from the glands of the mucous membrane, and to excite suppuration. Counter-irritation to the neck, moist heat externally and internally, by diminishing congestion, re-establishing the natural secretion, and promoting suppuration, closely imitate the unaided method of nature.

Rubefacients are important remedies in the treatment of diphtheria. Turpentine is a rubefacient which acts with great promptitude, which is no small consideration in a disease like diphtheria; this, together with the fact that its use may be continued over a long period, makes it the best of the rubefacients. By producing irritation and congestion of the skin, turpentine lessens the congestion and inflammation of the throat; and the swelling and soreness of the cervical lymphatics are rapidly diminished. Moist heat in the form of *hot* flaxseed-meal poultices, allay the inflammatory process at the margin of the pseudo-membrane, stimulate secretion, promote suppuration, and check the formation of false membrane. Where this has occurred the patches of pseudo-membrane already formed will be seen to be raised from the mucous membrane, and their surface to become wrinkled and uneven, and finally they become detached.

When moist heat is thoroughly used, the secretion in the throat and pharynx is less tenacious, it is more readily removed, either by expectoration or by being washed away by swallowing, and by medicine; there is therefore less need for spraying, etc.

Moist heat promotes resolution of the inflammation in the cervical lymphatics, softening these, lessening the soreness, and thereby giving great comfort.

In faucial, tonsillar, and pharyngeal diphtheria the whole neck, from the episternal notch to the lobes of the ears, is enveloped in a hot poultice. This must be covered with two thicknesses of flannel, and an outer covering of oiled silk. The poultice should be renewed every half hour or every hour. Where poultices are objectionable or are too troublesome, a much neater and very effectual mode of applying moist heat, consists in the use of spongio-piline frequently wrung out of hot water, tied around the neck, and covered with flannel and oiled silk.

To be convinced of the beneficial effects of poultices, very hot and frequently renewed, witness their value in wound diphtheria, where the process has resisted every other mode of treatment. There is nothing that promotes exfoliation of the membrane and checks spreading of the inflammation as a poultice does. Were it possible to apply a poultice to the tonsils and pharynx, we would quickly see a subsidence of the diphtheritic inflammation and a separation of the exudate. We imitate the action of poultices when we use steam inhalations; the physiological action and the beneficial therapeutic effect being much the same. It is the steam, and *not* the medicament used, that benefits the patient. A fluid in which diphtheritic membrane is soluble does not possess the power of dissolving that membrane when it remains attached to the vital tissues; hence trypsin and other agents recommended for this purpose are valueless as a solvent of the diphtheritic exudate *in the throat and air-passages*. For vaporization, nothing is more satisfactory in my experience than lime-water, two parts, to alcohol one part. The most convenient and safest apparatus for producing steam, and the one least likely to alarm a child, is the ordinary iron or tin croup-kettle with an alcohol flame, and a piece of stiff rubber-tubing extending from the spout of the kettle to the patient. At first the kettle should be kept at some distance from the child, and gradually brought nearer as it becomes accustomed to it. If fear and dread of this treatment cannot be overcome by tact, it may be resorted to only during sleep; in which case great care should be taken to have the apparatus removed if the child begins to awaken, that it may not be frightened, and thus interfere with future rest and management.

During the use of the steam the neck and chest of the child, should be covered with oiled-silk, lined with canton-flannel, so that its clothing may not be dampened. Steam should be used only for ten or fifteen minutes at a time, and at frequent intervals, shortened when the inflammatory process is excessive. Continuous use of steam would weaken the child, make him restless and cause him to dread it, but if used at intervals it is grateful to him, does not depress him, and is soothing in its effects.

Mild purgatives, diaphoretics, diuretics, counter-irritants, with moist heat externally and internally, if used judiciously and with discrimination, are beneficial at the very outset of the disease, as eliminants of the poison, as derivatives from the seat of disease, as evacuants of morbid secretions and excessive tissue waste, in checking the spread of the specific inflammation, in lessening the formation of false membrane, in exciting the activity of the secreting glands at the seat of the disease, and in lessening the tendency to involvement of the larynx.

During this disease more nitrogenous food should be taken and absorbed, and the vicariously-eliminating urea structures, as the skin and intestinal canal, should be maintained moderately active; but profuse sweating and purging, like every other excessive evacuation, is harmful. If the throat is much inflamed, the exudation firmly adherent, showing no tendency to exfoliate, even after the use of the above means, pilocarpine may be given. If there is undue exhaustion, pilocarpine must be used with caution.

If the child is very young, has recently had pneumonia, measles, or bronchial catarrh, if it is rachitic or has valvular disease of the heart, pilocarpine is almost an unsafe drug.

After the use of pilocarpine, the vascularity of the throat is reduced, the normal secretion is re-established, and the membranous exudate appears less tenacious; its extension seems to be arrested by the circumference of the patches presenting a less livid appearance and terminating more abruptly in the healthy mucous membrane, the patches at their edges begin to give evidence of commencing separation. In addition to its action on the throat, pilocarpine promotes the elimination of the poison.

The next indication is to counteract the effects of the poison on the blood, toward which purpose pure air, sunlight, and quinine play active parts.

The only known agent that is inimical to germ life, that is a perfect disinfectant, and is not only harmless to the patient, but is beneficial both in health and in disease, is sunlight. No disease-germ can long retain its vitality when exposed to the sun's rays. An important requisite in diphtheria, therefore, is to have the patient in a southeast room, no hangings at the windows, and the bed so placed as to receive the unobstructed rays of the sun from morning to night. Where this is done, the intense and persistent anæmia so common after diphtheria is not so marked, and convalescence is more satisfactory and progresses without interruption.

The sick-room should be further purified by having roll-sulphur burned in it at least three times in the twenty-four hours. The sulphurous acid gas thus liberated and inhaled by the patient has a decidedly beneficial local effect.

Another accessory is fresh air, which must be obtained at intervals during the day, moving the bed of the patient, if necessary, to keep him from the currents of air.

If full health and richness of the vital fluid render a person less liable to contract diphtheria during its prevalence, it is natural that iron, quinine, and other potent tonics, render the blood of the patient less favorable to the action of the morbific agent.

If the tendency to death is by asthenia, a stimulant-tonic treatment is urgently demanded, and depressants, except to meet definite indications, are to be avoided.

Dr. Thomas Heslop, of Birmingham, in 1858 introduced the tincture of iron as a remedy for diphtheria, and his words of caution should be considered at the present time: "My great fear is, that this method of treatment will be extravagantly lauded, that it will be called by the ignorant specific, and that on the occurrence of fatal cases under its use, as is inevitable in so virulent a disorder, it will be consigned to the limbo where so many other therapeutical abortions have been thrown."[1]

Dr. Heslop's fear was realized, and it was said because patients died that iron as a remedy against diphtheria had been overestimated. Death was the result of neglecting other indications, and from giving too small and too infrequent doses of iron.

Herr Aubrun, of Paris, in 1860, administered to a child twenty-one months old, fifteen drops of tincture of the chloride of iron every ten minutes during the day and every fifteen minutes at night. The child had diphtheritic laryngitis, with pulmonic consolidation. Tracheotomy was performed; the iron in these doses was continued, and ultimately recovery took place. Aubrun believes that recovery was largely due to the use of iron in such heroic doses.

Robert Druitt, in 1861, administered two drachms of tincture sesquichloride of iron every two hours for twenty-four hours, and three fluid ounces in five days. The record of the case shows that this quantity did good, and as Dr. Druitt remarks,[2] "it was evident that these doses did good, and it was probable that smaller ones might have failed."

One of the physicians of Middlesex Hospital gave one and a half ounces tincture of iron in twelve hours.[3]

Generally iron has not been given in sufficiently large doses to get the desired effect, nor have the doses been graduated by the form of the disease. Attendant upon the action of the diphtheritic virus is a decline in that nervous control which regulates the functions in health.

Tincture of the chloride of iron, in diphtheria as in erysipelas, increases the vital contractility of the blood-vessels, probably by its stimulant-tonic effect on the nerve and vascular systems, thereby preventing the spread of the disease-process.

To get the physiological effect of iron it must be given in full doses, in accordance with the type of the disease. Where there is marked sepsis and tendency to capillary hemorrhages, the dose should be larger than in a case of a less septic and more marked inflammatory character. If we are to obtain the decided effects of the drug in a case of septic diphtheria, at least one drachm of the tincture should be administered every hour, to a child two to five years old. We have given two drachms every half hour for forty-eight hours, or twelve ounces in two days, to a boy eight years old, with manifest good, and with no disturbance of the stomach. Indeed, there is no rule as to quantity. Instead of giving directions for definite doses, I should say be guided by the controlling influence of the drug on the disease-process. Give it *ad libitum* so long as the inflammatory and exudative process is spreading; as you would in erysipelas, until you see the dilated and dilating vessels contract, and the advancing redness brought to a pause. Iron is best given with an equal portion of glycerine. Chlorate of potass with the iron mixture enhances its efficacy. This combination was used in England almost immediately after the introduction of iron by Dr. Heslop.

[1] Thomas P. Heslop, M.D.: On Diphtheria, in Medical Times and Gazette, May 29, 1858, p. 554.
[2] British Medical Journal, February 23, 1861, p. 208.
[3] British Medical Journal, vol. i., 1861, p. 208.

The Report of the *Lancet* Sanitary Commission on Diphtheria,[1] in 1859, said: "Of the many internal remedies which have been advised, we do not know of any on which so much reliance can be placed as on the tincture of sesquichloride of iron in combination with the chlorate of potass." A valuable adjunct is quinine, which should be given in small tonic doses, where it does not irritate the stomach, and where it can be given without the child's tasting it. It can generally be administered in food or jelly to the youngest child in gelatin-coated pills of a fraction of a grain each. In many of the cases of diphtheria in New York alcoholic stimulants take first rank in the treatment. I do believe, however, from a very varied experience in dispensary, private, and consultation practice, that stimulants are too generally used at the *outset* of this disease. Unless there is marked sepsis, I do not find alcohol necessary during the first days of the disease, nor until the symptoms, particularly the pulse, give some indication of its need. As to quantity, we must be guided by the effect and the temperament of the patient. Some children with diphtheria bear surprising doses of whiskey or brandy with great benefit. Twenty or thirty drops every hour to a child one year old to begin with, increasing the quantity and the frequency according to the effect on the disease and the child. We must stimulate into activity the reserve nerve force whenever indicated by the failing strength, to preserve the powers of the system, and to maintain the functions of the important organs at an equable standard.

Nutrition must be carried to the highest point by means of concentrated nourishment, and, if need be, by rectal feeding. Bear in mind that the fever of sepsis indicates failing powers and excessive waste, and that it is relieved by maximum doses of iron with moderate doses of quinine, or, if very high, with antipyrin.

Local treatment.—This certainly is not curative in its effect, and the most that can be said for it is that by its local effect it may prevent the spread of the disease, and even this is questionable, and not so certain in its action as constitutional remedies intelligently and vigorously administered.

There is one insurmountable obstacle to the successful local application of a drug of known potency, even if we possessed one. It is only intelligent, older children who will submit to anything like thorough applications to the throat. Even with them, if well and frequently done, it will not long be borne without protests which end in a desperate struggle with every attempt. The exhaustion following such treatment has led me to abandon local applications, except in rare cases, and then only at long intervals.

When from the local anatomical changes, or from functional impairment of the larynx, we have reason to apprehend croup, the treatment should be modified accordingly. When we see bands of pseudo-membrane forming on the posterior wall of the pharynx, and descending down beyond our view, we have reason to dread invasion of the larynx. We know that a secretion on a mucous surface tends to macerate the false membrane of diphtheria, and promotes the resolution of the inflammatory action. The exudate which results in the formation of the false membrane is usually at first more fluid, less concrete than it is after its retention on the mucous surface, where it finally forms a distinct layer. For this reason an emetic should occasionally be administered when there is a disposition to extension into the air-passages, that it may be removed before it has become concrete. An emetic subdues the congestion in the larynx and stimulates the glandular activity, thus tending to prevent the formation and promote the removal of an inflammatory product. The employment of emetics is imperative in very young children who cannot expectorate, and in all cases where there is much accumulation

[1] London Lancet, February 12, 1859, p. 171.

of mucus, and children will not gargle—if there is a catarrh of the larynx, or much croup; if the voice is altered, or there is much inflammatory swelling in the fauces; if there is a snoring sound during sleep, even though there may be no other sign of laryngeal disturbance. Emetics must be used only occasionally, taking great care not to exhaust the child.

Ipecac, in the early stages of laryngeal invasion, is the best emetic, because it counteracts the inflammatory tendency better than any other of its class, and it is perfectly safe in judicious hands. At this stage steam should be frequently used. If it annoys the child, small doses of opiates may be given to allay irritability and induce sleep, so as to enable us to have recourse to steam. Restlessness, fretfulness, and loss of sleep exhaust the strength, lessen the appetite, promote the spread of the local lesion, and increase the danger of laryngeal invasion. In any nervous, restless, and fretful child opiates should be used, if necessary, to procure sufficient, uninterrupted sleep.

When a diphtheria is very persistent, or even after its entire disappearance from the throat it is constantly reappearing, the nasal passages should be examined. Many of the cases of sudden, unexpected death, after the complete disappearance of all evidence of the disease from the throat, are due to an unrecognized diphtheria lurking in the nasal passages, thus silently undermining the vital powers and ending in heart-failure—a sequence no less strange than it would be if the child were allowed to go about with an active faucial and tonsillar diphtheria. When recovery is protracted, or there are repeated relapses, even though the treatment is not suspended, always suspect and examine the nares. If there is slight illness, with injection of one eye, examine the corresponding side of the nose. When there is swelling on one side of the neck only, or the swelling on the two sides is unequal, being greater on the side where there is the least disease in the throat, you will be quite certain to find previously concealed patches in the nose or on the posterior pharyngeal wall behind the pillars of the fauces on the side corresponding to the greater swelling of the lymphatic glands.

When there is great swelling of the cervical lymphatics on both sides, with comparatively slight throat diphtheria, we have reason to investigate the nasal anfractuosities. When the pulse continues rapid, or unnaturally slow and irregular, if there is great prostration, anorexia, and nausea, examine the nares. In a word, then, it is always incumbent upon us, when diphtheria is prevalent, to examine with care the nasal mucous membrane of every sick child. Do not wait for visible manifestations, as the disease may develop here to a dangerous degree without warning and without symptoms, until the throat is invaded. I had a child brought to my office last summer from a summer hotel for what was supposed to be mumps, it proved to be a bad nasal diphtheria. Nasal diphtheria is almost always insidious in its outset, often for a long time remains indolent, then giving rise to excessive diphtheritic infection, the *recognized* disease being very sudden in its attack. The gradual extension of a nasal diphtheria to the throat sometimes causes but little soreness, and the first warning of its existence is from the occurrence of croup (see p. 621).

We are especially liable to find nasal diphtheria in children with diphtheritic patches about the lips, or who have cutaneous diphtheria.

Nasal diphtheria, if recognized in its beginning, in a child of average health is not very dangerous. With prompt, painstaking treatment, it can usually be kept in check and subdued without serious symptoms. In nursing infants, with much swelling of the mucous membrane, there is great danger, owing to their inability to nurse, that starvation or suffocation may take place. Management, however, on the part of an experienced and competent physician will triumph over these difficulties. Thorough and frequent disinfection is very necessary here. For this lime-water, equal parts of it and saturated solution of chlorate of potash; lime-water, with ten or fifteen drops of carbolic acid to the ounce; and salt water, with alcohol, are good. There is nothing better than the last. A weak solution of salt, with a little alcohol in it, increasing the strength gradually, taking care not to have it irritate, cleanses and disinfects thoroughly, *if thoroughly done*. After this, the application, with a feather or camel's-hair brush, of a ten per cent. ointment of iodoform is one of the best that I have used.

Prognosis.—If the outset of the disease is active, and it is recognized and treated early, the prognosis is good. With a sluggish inception, late recognition and treatment, the prognosis is questionable. In a child who has recently had measles or scarlet fever, or who is recovering from whooping-cough and has catarrh of the air-passages, there is danger of complications and of early exhaustion. If any other epidemic disease which the child has not had is prevalent at the time, and he has been or will be exposed to it, the prognosis is serious.

The existence of scrofula makes the prognosis more grave. All of these call for a stimulating and supporting treatment throughout the disease. When the patches of pseudo-membrane are thinner at the edges than at the centre, and are surrounded by a red border of angry-looking inflammation, we have more cause to dread the disease spreading than when the membranous patch is thick at its edges, with a tendency to become circumscribed. Loosening and signs of detachment of the patch at its edges, and puckering of the same, are indications of an arrest of the disease, and of a beginning reparative process.

When there is diphtheria in a family where there are several children, and they cannot be removed, every child should be daily submitted to an examination of the lymphatics in the submaxillary region and the fauces.

Children who are not feeling well will not complain, and even when questioned will say that they are not sick, from the fear of an examination of the throat and of treatment. They should be kept as much as possible in the open air, and given iron, quinine, and the most nourishing plain food. No case of diphtheria, however slight it apparently may be, even if it be limited to a single patch of membrane, can be neglected but at the risk of life. I know that in this statement I make myself liable to the imputation of being an alarmist, but a sufficient experience justifies the declaration.

Dr. A. Jacobi,[1] on "Prognosis of Diphtheria," says: "But the physician will often enough be deceived, and more frequently, too, in mild than in bad cases." The mild case, through inattention and want of conservation of strength, and from exposure and catarrhal complications, is allowed to become a severe one. There is nothing mysterious about sudden death in the majority of diphtheria patients, nor in the mild cases developing diphtheritic laryngitis. True, we will occasionally meet a case of diphtheria where, owing to scrofulous glands or other constitutional peculiarity, the poison, despite careful treatment, will remain a long time stowed away in the system, liable to be at any moment discharged into the blood; but the observant practitioner is rarely deceived by such a case.

If, after the disappearance of the local lesions, fever, cachexia, and glandular swelling persist, we have reason to fear the reappearance of the exudate; and the continuance of any one of these, or of a small thready pulse, should be sufficient to make us vigilant. Progressive loss of appetite during convalescence is a serious symptom, and when accompanied by vomiting we have reason to apprehend a lesion of the pneumogastric nerve. Morphia, hypodermatically, is one of our best remedies for controlling this vomiting. Sleep, at all times necessary, is, at the latter part of this disease, especially important, and it is now that opiates are well

[1] Jacobi: On Diphtheria, p. 149. New York: William Wood & Co., 1880.

borne. When there is nocturnal delirium, with considerable elevation of temperature, quinine and iron, the latter in maximum doses, are to be given, and they control both symptoms.

In nursing-children iron and quinine should be given to the mother as well as to the child. In bottle-fed children the saccharated oxide of iron may be given in the milk without danger of disgusting the child; twenty grains may be given in this way every two or three hours. Children with diminished appetite and digestive powers may be given pills of raw beef and pepsin. Pepsin should be freely used in every case where there is much prostration. Use peptonized food where there is much depression. When there is nausea give peptonized foods by the rectum. Every attention must be given to keep up the nutrition and strength, and to prevent any unnecessary further withdrawal of remaining vital power.

These methods of treatment lend mutual aid to one another; any one is insufficient without the other; and cases will be met with where a modification of this system-management will be necessary. No written plan of treatment should be allowed to supersede the physician's judgment. To know the natural history of diphtheria, to have a knowledge of indications, and a discriminating judgment, is to possess ourselves of the beacons by which we are to be guided in the treatment of this disease.

THE GALVANIC CURRENT IN CHRONIC PELVIC CELLULITIS.

By A. D. ROCKWELL, M.D.,

NEW YORK.

While electricity as a therapeutic agent undoubtedly finds its widest field in neurological cases, yet it is by no means to be restricted to these conditions. In every special department of medicine it must at times enter as an important factor, and if both general practitioner and specialist would keep abreast the current, they must recognize this fact. Ophthalmology, laryngology, dermatology, and obstetrics even, own its value, but it is in gynecology that its greatest efficacy lies.

I have for years held that it should occupy a far higher place in the armamentarium of the gynecologist than it has yet occupied, and have occasionally given such testimony as I could concerning its efficacy in the disorders of menstruation, in super- and sub-involution of the uterus, in uterine morbid growths, and in certain ovarian disorders. Until gynecological experts more generally, however, give the subject their personal attention, make themselves familiar with the physics and physiology of electricity, study the differential indications for its use, and finally supplement theoretical knowledge by practical work, the popularization of this invaluable remedy for the diseases of women will be slow.

In the sequelæ of pelvic cellulitis especially, the application of the galvanic current is not infrequently followed by the most satisfactory results. For the absorption of old exudations in other parts of the body, this form of electricity has long been known to be most efficacious, but only within a comparatively recent period has it been tested in the thickening and infiltration resulting from inflammation of the pelvic cellular tissue. The negative pole, consisting of a metal ball, or in some cases, better still, of a concave metal clasp, is to be used internally and directly to the part affected, while the positive is to be applied externally. If the metal electrode is applied without the intervention of a sponge or chamois covering, care should be taken not to use currents sufficiently strong to produce eschars. This mishap may occur even without the knowledge of the patient at the time, and in the beginning it is, perhaps, safer to use a covered electrode. I have seen this treatment, judiciously and persistently carried out, result not only in the absorption of large pelvic deposits, but in the cure of the most severe and obstinate sciatica and in the restoration of power to partially paralyzed limbs. In such cases both sciatica and paralysis are caused undoubtedly by pressure of the exudations upon the pelvic floor, and can be relieved only through the dissipation of the morbid products.

From among a number of cases I select the following as illustrative, in a very striking manner, of the foregoing remarks:

In October, 1884, Mrs. S——, aged thirty-three, came to me complaining of a multitude of symptoms. She could walk only with difficulty and for short distances. The appetite was poor and constipation excessive, associated with a constant pain in the basilar region as well as in the lower portion of the spine, while a constant "burning and pressure" in the uterine region contributed to make her life quite wretched. In addition to all this, she suffered from dysmenorrhœa and menorrhagia and very severely from sciatica.

Upon suggesting to her the probability that local causes prevailed, and that local treatment was called for in her case, she refused to entertain the idea, saying that she had for a long time submitted to local treatment, and, as she believed, with evil results rather than good.

At all events she was now suffering more than ever before. All that she wished for or would consent to receive were some general applications of electricity, in the hope that some of its constitutional tonic effects might become manifest in her case. She came to me irregularly, as suited her caprice, for a number of months, and was treated by both forms of dynamic as well as by static electricity. She received some benefit as to her appetite, and in lessened pain along the spine and back of the head. The objective evidences of improvement also were but slight, and were seen only in a somewhat easier movement of the limbs. Through the confidence begotten of these inconsiderable signs of improvement, she finally consented to an examination. I found the neck of the uterus crowded somewhat backward and to the left side, while the left half of the os uteri was almost completely obliterated.

The enlarged portion was harder than the surrounding tissue, but not acutely sensitive to moderate pressure. Pressure along the base of the swelling and posterior to the os caused greater pain. My idea in making this examination was, that it would be preliminary simply to directing her to some competent specialist in diseases of women, but when I discovered what seemed to me to be extensive exudation in the connective-tissue, I determined to submit her to persistent localized galvanization. For nearly a month the patient came every day, with the exception of Sundays, and subsequently visited me about every other day for three months. The applications were made directly to the diseased part, and when menstruation appeared some three weeks after the inauguration of the local treatment, the flow was not only markedly less in quantity, but attended by a very considerable decrease of pain. In a few weeks the distress along the sciatic nerve entirely disappeared, and the progression toward a fair condition of health was uninterrupted until she was discharged as cured, after having received fifty-six local applications of the galvanic current. Under the absorptive influence of the current the inflammatory exudation gradually disappeared, until in the end the finger could be swept entirely around the neck at its juncture with the body of the uterus. In the recital of a case of this character the question very naturally arises, What are the points aiding in the diagnosis aside from those already detailed? For if this were a case of chronic parametritic exudation, as there is every reason to believe, it must be of exceeding interest to every practitioner, general or special, who has to deal with female diseases. As obtained from the patient when I first discovered the character of the local trouble, her previous history is as follows: About two years before I saw her, she aborted at the third month, suffering considerable pain, but within a fortnight regarded herself as "quite

smart." At this time she took a ride of several miles over a rough country road, and when she reached home was very tired and chilly. During the night she had considerable fever, with sharp, local pains.

From that time onward she suffered almost constantly from dull pains high up in the vagina and through the lower part of the abdomen. Her menstrual flow had always been perfectly normal, but now it suddenly became profuse and painful, and continued so for two years or more until she began the local galvanic treatment. Especially suggestive was the readiness with which the sciatic neuralgia disappeared under applications directed to the enlargement, clearly indicating that the cause of the sciatica, as well as of the incomplete paraplegia, was the pressure of the parametritic exudation on the pelvic floor.

THE HEART—ITS POSITION AND MURMURS.[1]

By WILLIAM H. PORTER, M.D.,

PROFESSOR OF CLINICAL MEDICINE AND PATHOLOGY AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, CURATOR OF THE PRESBYTERIAN HOSPITAL, ETC.

In order to obtain a clear conception of, and to readily recognize the various cardiac murmurs, a thorough knowledge both of the exact position of the organ and of the mechanico-physiological laws which govern it are indispensable. This is especially true in regard to those murmurs which are located at the mitral orifice when there is no organic lesion of the valve segments.

The etiology of murmurs of this class has been in doubt for a long time, and has given rise to an endless amount of discussion *pro et con.* It is the purpose of this paper to attempt to throw some light on this subject.

If, as usually is the case, the anatomical position of the heart is taken from frozen sections, it will appear upon a lower plane than that which it actually occupies during life, unless an allowance is made for the sinking which occurs with all the viscera, and especially of the thorax, after death. During life, too, the heart cavities and great vessels are distended with blood, which naturally causes the viscus to occupy a higher position in the chest than would be the case under other circumstances.

During life, therefore, the heart may be said to occupy a triple oblique position in the chest, or one corresponding to a line drawn from right to left, from above downward and from behind forward.

The base will correspond to a line drawn across the sternum from the first intercostal space of the left side to the second intercostal space of the right side, and its apex will be found at the fifth intercostal space of the left side, three and one-half inches from the median line.

The left side of the heart is the most posterior; this is especially true of the left auricle, which also is the most inferior portion of the organ, lying as it does adjacent to the eighth dorsal vertebra, or deep down between the diaphragm and the spinal column.

As a result of this posterior and inferior position of the left auricle, the current of blood passing from it into the left ventricle naturally flows from behind forward from right to left, and slightly from below upward. Or it corresponds to a line drawn from behind through the eighth dorsal vertebra, through the chest, and coming out in front at the junction of the fourth costal cartilage and its corresponding rib. This line for convenience is called the left auriculo-ventricular axis. From this description it is readily seen that the biscuspid valve is situated well behind on this axis.

All the murmurs, therefore, that occur at the left auriculo-ventricular orifice are produced and transmitted by the current of blood passing in one of the directions of this axis.

Organic lesions of the bicuspid orifice are pretty thoroughly understood, but that condition in which positive evidence of mitral insufficiency is obtained upon physical examination during life and the necropsy reveals a perfectly normal and competent valve, have not been so satisfactorily discussed.

Murmurs, the result of organic lesions, are divisible into two classes—those due to obstruction at the orifice and those due to an incompetency of the valve.

The causes of the organic obstructive murmur are acute endocarditis, with roughening of the valve by outgrowing vegetations, congenital malformations, chronic endocarditis, with or without calcareous depositions, which narrow the orifice, and all of which prevent a free egress of blood from the auricle.

The etiology of the regurgitant murmur at the mitral orifice from organic causes are acute and chronic endocarditis, with their resulting retraction of the valve segments; rupture of a segment of the valve, or rupture of a chordæ tendinæ, and acute and chronic dilatation of the left ventricle.

With organic narrowing of the bicuspid orifice a murmur is produced in the auriculo-ventricular axis by the obstruction to the normal current of blood. It is called a presystolic murmur. This is true so far as the ventricle is involved, but in reality it is a systolic murmur of the auricle, and occurs at the height of the auricular contraction. This murmur is heard with greatest intensity at the point where the auriculo-ventricular axis strikes the anterior surface of the chest-wall, or at the junction of the fourth costal cartilage with its rib. It is high-pitched, and is practically not transmitted, being heard only over the limited precordial area. It is usually of short duration, but may be somewhat prolonged if the obstruction be very great.

With an organic incompetency of the bicuspid valve a murmur is produced by the blood being forced back from the left ventricle into the auricle against the normal current. It is distinctly heard at the apex, is transmitted to the left, often lost at the axillary line, but is heard with equal intensity behind at the inferior border of the seventh dorsal vertebra, or between this point and the inferior angle of the left scapula.

According to the ordinary law of production and transmission of cardiac murmurs, this murmur should be heard behind only; but occurring as the result of the ventricular contraction, when the heart becomes as it were a solid body and strikes against the bony chest-wall, which is also a dense body; they, together, obey the general law of transmission of sound by dense bodies, and bring the sound distinctly to the anterior surface of the chest.

At one time we were taught that a systolic murmur at the apex, if transmitted to the left and heard behind, always indicated an organic lesion. This, however, does not always hold true at the mortuary, and still more infrequently at the bedside and in the clinic room.

A functional obstructive murmur of the mitral orifice is often heard in cases where there is considerable aortic regurgitation, the regurgitated blood fills the lower portion of the ventricular cavity, floats the inferior bicuspid segment too quickly up against the incoming blood from the auricle, and produces an obstruction which gives rise to a quick, sharp, and decided obstructive mitral murmur.

It is differentiated from an organic murmur at this valve by its disappearance when the heart is stimulated, and the aortic regurgitation is diminished, or in part compensated for by the prolonged systolic act and diminished diastolic pause.

The functional regurgitant murmur at the mitral orifice is the one of greatest importance, on account of its frequent occurrence, and because it is so often mistaken for a sound due to a positive organic change.

This has been explained by a powerful contraction of the left ventricular wall, causing an over-closure and a forcible sliding of the valve segments upon one another, and thus producing the sound; but while this might hold

[1] The substance of this paper was read at a meeting of the Clinical Society of the New York Post-Graduate Medical School and Hospital, March 7, 1885.

true in a few instances, it is not sustained, in the majority of cases, by the necropsy findings.

To have friction enough to produce so loud a sound would necessitate a roughening of the valve, and would lead to a positive thickening of the leaflets.

This, however, is not the case; for at the necropsy the valves are found perfectly smooth, thin, and absolutely free from any lesion.

The physical signs also disprove this theory. For a murmur produced by too tight closure would not give rise to any regurgitation of blood at this orifice, and consequently there would be no distinct murmur heard behind. A sound heard at the apex and after the first sound, not transmitted nor heard behind, might be attributable to such a condition.

Those cases in which a positive murmur is heard in front over the apex or mitral indirect area, transmitted to the left, and heard with equal intensity behind, near the seventh dorsal vertebra, or between it and the inferior angle of the left scapula, and where the necropsy reveals no organic lesion in the segments of the bicuspid valve, and no dilatation of the left ventricle, but in which the gross appearances of the valve and of the heart itself are normal, deserve special attention.

If we stop for a moment and consider the anatomico-physiological mechanism of the heart the explanation is easy. As is well known the ventricular wall is composed of seven distinct layers of muscle-fibres, or for simplicity they may be considered as four. We have, connected with these layers, two sets of papillary muscles, one springing from the anterior, and the other from the posterior wall of the ventricle, to which the bicuspid segments are guyed by the chordæ tendineæ. When everything works in unison the two segments of the valve float toward the auricular cavity, and their margins are brought together at a given point, and held there by the equal and synchronous contraction of the two sets of papillary muscles and the tension of their chordæ tendineæ. In this way the auriculo-ventricular orifice is perfectly closed and regurgitation absolutely prevented.

If for any reason the innervation of the heart is unequally distributed to the different layers of muscles, or the muscular layers become unequally nourished, their unity of contraction is disturbed, and instead of this perfection of action just described, one set or layer of muscles contracts more forcibly or more quickly than the other, and the papillary muscles shorten irregularly and unevenly. As a result, when the ventricle contracts, one segment or the other fails to stop at just the exact point to meet its opposite, but is forced on into the auricular cavity, while its opposing fellow-segment is drawn more completely into the ventricular cavity. Consequently, instead of a complete closure of the orifice, an actual gap or insufficiency occurs, just as perfectly as if a piece of the valve was wanting, a positive escape of blood from the ventricular to the auricular cavity takes place, which of necessity gives rise to all the physical signs of an organic insufficiency with regurgitation. The temporary results are the same as if there was a positive and irreparable defect. The rational signs also are the same in both instances.

Organic and functional insufficiency at this orifice can easily be differentiated during life, not by their rational or physical signs, however, but by an appropriate plan of treatment. If the cause of the former be a deficient innervation, by giving such remedies as will restore the nerve power the signs and symptoms will be found to quickly disappear, all regurgitation be prevented, and the patient freed from all the unpleasant symptoms. When due to deficient nutrition, with a lack of uneven, or an innervation and irregular muscular action, true cardiac stimulation will cause a like result.

If, on the other hand, the physical signs are due to positive defects in the valve, the same line of treatment will often decidedly improve the condition of the patient, but will not cause a disappearance of the physical signs. It may shorten the duration of the murmur, but the abnormal sound will be more intense and more easily and accurately recognized.

By a true cardiac stimulant is meant a remedy which prolongs and increases the force of the systolic act, and at the same time reduces the number of pulsations per minute and shortens the diastolic period. If, however, the heart is running very rapidly, slowing of its action will cause both the systolic and diastolic act to be lengthened, but the total diastolic pause will be shortened, and at the same time the inherent force of each contraction will be increased.

The medicinal agents which accomplish this result most effectually are opium and its alkaloids, ammonia and its salts, and alcohol, all of which have this tendency to prolong and increase the force of the systolic act and improve the effectiveness of the diastolic pause. At the same time they only contract the arterioles to a slight extent, which in turn permits the largest possible volume of blood to pass through the coronary arteries and cardiac capillaries in a given space of time, and in this way raises the nutrition of the organ to the highest degree attainable. To these may be added nux vomica and belladonna, or their alkaloids, on account of their stimulating effect upon the nervous mechanism of the heart.

Digitalis or its alkaloids is not a true cardiac stimulant in the physiological sense of the word, for it does not prolong the systolic act, nor is there sufficient proof yet advanced to sustain the theory that it increases the force of the systolic contraction. True it modifies the rapidity of the heart's action, which in all probability is due to the high arterial tension, which, in turn, necessarily calls for increased work on the part of the heart, and it slows down to try and overcome the increased resistance.

This high arterial tension and rapid circulatory current is what physiologists teach us retards nutrition, the very thing to be prevented if a compensatory hypertrophy or increased nutrition of the cardiac muscles is required.

The starvation of the heart by the high arterial tension, and the increased amount of work upon a deficient nutrition, appears to explain the true mechanism of the so-called accumulative action of the digitalis.

In mitral incompetency a little good would result from the shortened systolic act, but it is a question whether the good is not more than overbalanced by the decreased cardiac nutrition which is produced by this drug.

In lesions of the aortic orifice, and especially in aortic regurgitation, no one will question the inadvisability of digitalis.

Convallaria, like fox-glove, acts upon the heart indirectly through the vaso motor system, and its influence in relaxing the arterioles removes the pressure from the heart and apparently increases its force.

Whatever line of treatment is adopted, rest, abstinence from all excitement, and from alcohol, except in medicinal doses, should be the rule. The bitter tonics, and especially some iron preparation, should not be omitted.

102 East Thirty-first Street.

New Journals.—We have received the first number of *La Normandie Médicale*, a new bi-weekly medical journal published in Rouen, France. Its aim is to unite more closely the physicians of Normandy in a spirit of fellowship, and to advance their common interests, presenting them also with the opportunity to chronicle the cases of interest occurring in their daily practice. Another new periodical is the *Gazette de Gynécologie*, published monthly in Paris. In the second number the editor, Dr. P. Ménière, announces with pardonable pride that the success of his undertaking is already assured, and to judge from the contents of the first two numbers this success would seem not to be undeserved.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 5, 1885.

A NEW THEORY OF PYREXIA.

THE development and regulation of animal heat are among the most interesting of vital phenomena, and the perturbations of this process, as illustrated in fever and in the subnormal temperatures of the insane, are of the deepest import to the physician. While we do not yet know the intimate pathology of fever, our knowledge of its phenomena, of the conditions attending it, is vastly greater, and our conceptions of its nature much more clear and satisfactory than was the case even a decade ago. In fever there is relatively an increase in the production of heat, and an increase in its radiation. The amount of carbonic acid gas and of urea excreted is increased. This increase in heat has been thought to be due simply to an increase in the metabolism or disintegration of tissue, and some investigators have brought forward considerable evidence to show that such increase of chemical change is due to the nervous system letting go its hold on the metabolic process; that there is, in other words, paralysis of a certain inhibitory thermic centre. But it is not possible, according to some authorities, to explain the great production and loss of heat occurring in fever by the fact of an increased chemical activity.

Dr. W. M. Ord, in his presidential address before the London Medical Society, offers a further explanation, which is striking and ingenious. It is generally admitted that in the process of building up the complex tissues from the simpler food products there is a loss of heat, *i.e.*, it is rendered latent. This view is strengthened by certain experiments of Dr. Ord upon the growth of plants. In fever this constructive process is disturbed, heat is not locked up as it should be, but continues kinetic, and goes to join the heat produced by excessive tissue combustion. There is then in fever, through disturbed nervous influence, interference both in the constructive and destructive metabolic processes.

This theory is characterized by Dr. Broadbent as "one of those flashes of insight which at once lights up the whole subject, and needs no more proof than does a poem."

The theory would be much strengthened, in our opinion, if Dr. Ord could show that the increased amounts of urea and its allies excreted in fever came in disproportional amount from the food and "circulating albumin." For if there is excess of heat from deficiency in assimilation of food, evidence of this would appear in the excretions.

In this connection a letter from Dr. Charles A. Rayne to *The Lancet* is of interest: "One day last week, during an ascent of one of the lake mountains, nearly three thousand feet in height, I made the following observation. When half way up, and during the ascent of a very steep and rugged bit, I took my temperature in the mouth very carefully. It was 95.5°, though I was feeling very hot at the time, and respiration was largely increased. When nearing the top, and walking leisurely up a slighter incline, I again took it, and found it 97.5°. After resting at the top some time, and feeling chilly in a cold wind, it was 98.6°. These experiments are not new. I tried them some years ago with similar results, and I believe they were first made public in a letter from the pen of Dr. Tempest Anderson, published in *Nature* ten or fifteen years ago. Their bearing on the problem in question is evident. During the raising of the body to the height spoken of these experiments seem to me to point to the fact that there is largely increased constructive metabolism, probably in the muscular tissues, and a locking up of heat in consequence, resulting naturally in diminished temperature of the body as a whole. A similar explanation may not improbably explain the normal diurnal variation of temperature observed in health."

INIQUITOUS DECISIONS.

THE legal and medical professions are generally on very good terms with each other, in this country at least. But there are at times some most extraordinary and unjust decisions sent down from the bench upon us. One of the most glaring instances of this was the case of Dr. Bradley, in whose behalf the medical profession of England has shown so much sympathy and generous help.

Now we hear of a case in California quite as iniquitous, judging from the facts given in the *Pacific Medical and Surgical Journal.*

In April, 1884, Dr. Graves, of Petaluma, Cal., was called to see Mrs. Winters, the wife of a laborer whose family he had attended gratuitously for nearly sixteen years. He found that the woman, who was fifty-eight years of age, had fallen from a height and injured her ankle. The limb was very much swollen, so as to interfere with examination, but no crepitus could be elicited, neither was there any displacement or shortening; and, as the swelling continued, the limb was placed in position and wrapped loosely in cloths saturated with anodyne lotions. The patient, we are told, received every attention from Dr. Graves, but there was left finally some stiffening of the joint and a very slight inversion of the foot. No complaints were made until a new doctor arrived in the town, who told the patient that the limb had been badly treated, and advised her to sue for malpractice. "The case," continues the *Journal*, "was examined by ten of the chief surgeons in the State, including Drs. Lane, McLean, Morse, and Dennis, all of whom said that there might have been a sprain or an incomplete fracture of the external malleolus, but that the ends of the bone were in perfect apposition and never had been separated, and that the stiffening was probably due to inflammatory adhesions.

"Two other doctors, one of them being he who advised the suit, testified that there was shortening of the limb, and that the lower fragment of the tibia had been driven up and behind the fibula. One of these would-be surgeons, Dr. Wells, is nearly eighty years of age, and had not read a work upon surgery for thirty years; the other, Dr. Ivancovich, confessed that he had no special experience in surgery. Their incompetence may be judged from the way they measured the patient's limb *in court*. This was done by taking a carpenter's rigid rectangular rule, and measuring the limb as she maintained the upright position.

"The result was that in the opinion of nine jurymen the testimony of two unknown, inexperienced general practitioners outweighed that of ten specialists in surgery, all of whom are well known throughout the State, and some of whom possess a national reputation, so that a verdict was returned in favor of the plaintiff, awarding her $8,000 damages."

It appears to us, from the facts given, that this decision is so gross an outrage upon the profession, as well as so great a personal injustice and misfortune to Dr. Graves, that the physicians of California are in duty bound to help straighten out the matter. They should either get the decision reversed, or contribute to the needs of Dr. Graves.

THE ONE-IDEA SYSTEM IN THERAPEUTICS.

NOTHING is so striking in medicine as the occasional success of certain men of one therapeutical idea. Given a certain dietetic measure, or potent drug, or ingenious mechanical appliance, let its user apply it continuously, confidently, and with a certain reserve of mystery, and he will be almost sure soon to become overrun with patients.

The practising physician is continually running against these gentlemen, who are curing cases by methods which, when applied by himself, often fail. Who has not heard of meat and hot water, of prisms and tenotomy, of Clemen's solution and diabetes, of electrolysis and strictures, of Apostoli and his galvano-cautery, of spinal ice-bags and the ganglionic system.

It is one of the instructive though not very satisfactory features of the medical art, this success of these one-idea artists. We know that in many instances they not only draw great numbers of patients, but cure a good many of them. It is not safe, however, for any one to infer that he can go and do the same thing. We do not hear of the numerous therapeutical "cranks" who fail miserably with their hobbies. Besides, there is large room for the suspicion that these monotherapists are dishonest, and on the whole do more injury than good.

THE DANGERS OF SUBCUTANEOUS INJECTIONS OF ETHER.

THE practice of injecting ether under the skin in cases of collapse, in which prompt stimulation is demanded, is so common and, in the main, so satisfactory in its results, that we are apt to forget that serious consequences may ensue. Several cases of this nature have been collected by a recent writer in the *Gazette Médicale de Paris*, in which sensory or motor paralysis of a member was caused by the hypodermic injection of ether. And Barbier has related a case of perforating ulcer of the foot believed to be due to the same cause. The anæsthesia and paralysis were probably caused by the action of the ether, and not by injury with the needle, for Pirogoff has shown that ether exerts an injurious effect upon the nerve-structures, and further, paralysis has never, so far as we know, been caused by puncture of a nerve by the needle used in giving subcutaneous injections of solutions of morphine.

POST-MORTEM ALBUMINURIA.

IT has been found by MM. Vibert and Ogier, that the urine drawn from the bladder of a cadaver is almost invariably albuminous, even when there was no lesion discoverable in any part of the urogenital apparatus. It was noticed in their experiments, also, that the longer the time was since death had occurred, and the less urine there was in the bladder, the greater was the proportion of albumen contained in it. The source of the albumen in these cases was shown to be the mucous membrane of the bladder, for, when the bladder was removed from the cadaver, emptied of its contents and washed, and then filled with distilled water, this fluid was found in a short time to become markedly albuminous.

This is a point well worth bearing in mind in the examination of the bodies of those who have died suddenly. For the mere fact of there being albuminous urine in the bladder would be insufficient to base a diagnosis of renal disease upon, and should not be given great weight unless corroborative pathological changes were also found in the kidneys.

THE QUESTION OF OPERATION IN CARCINOMA OF THE BREAST.

IT is the opinion of most writers that carcinoma of the mammary gland is a condition that calls imperatively for operation, not only to relieve pain and free the patient from a disgusting sore after ulceration has occurred, but also to prolong life. As to the latter point, however, there is not perfect unanimity among authorities—rather less, indeed, than is generally supposed by those who have not studied closely the more recent literature of the subject. There are symptoms of a threatened reaction in the mind of the profession, and it is not beyond the range of possibilities that, not many years hence, operation in cancer of the breast will be as exceptional as non-interference is now.

In the article on Carcinoma in the "Reference Handbook of the Medical Sciences," edited by Dr. Buck, the author, Dr. Satterthwaite, says that the statistics in a small number of cases would indicate that life is prolonged by operation for an average of more than eleven months, an estimate which he regards as a low one; yet he states that in his cases the growth of the disease was more rapid after removal. Dr. Lemaître, in a short paper read before the Société de Médecine de la Haute-Vienne (*Journal d'Accouchements*, October 15, 1885), argued strongly against the advisability of an operation, and asserted that the subjects of mammary cancer lived longer when the policy of non-interference was followed than when the tumor was removed. Boyer says that the extirpation of a tumor of undoubted cancerous nature should never

be undertaken. Morris believes that the surgeon should consent to operate only upon the urgent solicitation of the patient, and after she has been told of the probable recurrence of the disease. Velpeau, who regards cancer as primarily a local affection, says that an operation is justifiable only at the very incipiency of the trouble. And, finally, Verneuil has expressed some doubts as to the advisability of amputation of the breast, having observed after operation many cases of pleurisy which he regarded as cancerous in their nature. Lemaître's plea is that, as long as the cancerous disease is allowed to concentrate itself in the breast, the internal organs are comparatively safe, but that removal of the mammary gland invites a metastasis to other more vital organs.

The question is one which has not yet resolved itself into an axiom, and the indications are that it is destined to be the subject of still further discussion before it can be regarded as settled.

A STRIKING INSTANCE OF MIND PROPHYLAXIS.

We have had this week one of the most striking experiments whereby has been proven not only the efficacy of the mind-cure, but what the mind, under favorable circumstances, is capable of as a means of prophylaxis. It is seldom that so perfect an exemplification of the utility of animals as a medium to gain correct pathological results is seen.

Two confectioners were placed on trial for selling candy made of decayed cocoa-nuts, and unfit to eat. Not to hale to justice men innocent of the serious offence alleged, Dr. Edson tried upon his horse a couple of the cakes. The animal was made frightfully sick. Upon this evidence the candy-makers were brought before a jury.

The judge, probably unaware of the recent discoveries of the influence of mind over disease, asked the plaintiffs if they would eat the candy, using this as a test of innocence. They were perfectly willing to do so, and ate the confection, when it was handed to them, with such apparent satisfaction, that the jury one and all felt that they must test it too. The tempting sweet did not make any of them sick, therefore the prisoners were acquitted, the argument, of course, being that that which would not make prisoners and jury, including the foreman, ill, could not be injurious to children, even though it made a horse sick. They left out of consideration, which sometimes happens with jurors, the influence of the mind. The horse, uninfluenced by external considerations, allowed his equine mind no play in the matter, therefore the candy acted as it would naturally be supposed to, were it of the nature the analysis showed it to be; while when eaten by the prisoners, the power of the mind was such that it inhibited the evil effects and psychologized the jury into eating it with childish gusto, and to believe that no ill-effects could possibly arise.

In this instance there is a novel and instructive exhibition of a new and most beneficent method of the mind-cure—that of mind prophylaxis. We forbear to enter into the legal aspect of the question, but one can see at a glance that it is very grave, and that it gives rise to a new complication in the already too tangled net of the law.

A NEW URINARY TEST.

There is often considerable difficulty in making a positive diagnosis in the early stages of typhoid fever. Malarial fevers, acute general tuberculosis, and other febrile conditions may resemble for a time the early stages of typhoid. For this reason the peculiar urinary reaction occurring in typhoid and typhus, to which attention was called by Dr. Dana at a recent meeting of the Practitioner's Society (see page 635), is of much interest. This test consists in adding to the urine an acidulated solution of sulfanilin acid. The mixture is then made alkaline by the addition of ammonia, and allowed to stand for twenty-four hours, when a greenish colored deposit of phosphates occurs. This reaction is scarcely ever seen in the urine of healthy or afebrile persons, and very rarely, indeed, in the urine of febrile cases, except those of typhus, typhoid fever, and measles. Consequently its appearance in the urine may have a strong and important confirmatory value in diagnosis.

Professor Ehrlich, to whom we are indebted for this test, believes also that it has a prognostic significance in certain cases of chronic phthisis and of pneumonia.

News of the Week.

Medical Mayors.—At the recent elections in England eleven cities elected medical men as mayors.

The International Sanitary Conference which was announced to be held in Rome in December will not reassemble. The *Opinione* says, in an inspired article, that "after the discussions of last summer, which demonstrated the deep divergences of opinion between the representatives of the various Powers, and the hopelessness of their coming to an agreement, the re-convocation of the Conference would be devoid of any practical aim."

An Indiscreet Doctor.—Dr. Haywood Smith, a well-known and highly esteemed London physician, was unwise and imprudent enough to allow himself to be inveigled into the Armstrong case by Mr. Stead. He chloroformed the girl, examined her, and certified to Mr. Stead that she was "pure." The English medical press naturally condemn his action, and the British Gynecological Society have accepted his resignation as Secretary, expressing their thanks, at the same time, for the distinguished services he has rendered to this Society, and affirming "their belief that in what he did in reference to the Armstrong case he was actuated by what he believed to be the highest motives, while committing a grave professional error."

Cocaine-poisoning from an Unusually Small Dose.—Dr. T. H. Burchard, of this city, sends us the following case: "A brief mention of the following case may serve to call the attention of the profession to the possible dangers incidental to the hypodermic injection of cocaine. I was recently called to remove a needle from the sole of the foot of a young man whose personal characteristics doubtless had much to do in precipitating a condition of things that were well-nigh fatal. He was a tall, 'white-livered' youth of twenty-two years, standing six feet two inches, and weighing one hundred and twenty-pounds. He was remarkably white—complexion,

eyes, hair, etc. To deaden sensibility, I injected beneath the skin, close to the needle, *ten drops* of a four-per-cent. solution hydrate of cocaine. In about four minutes my patient suddenly clutched his throat, exclaiming, 'I am dying,' and fell from his bed unconscious. Respiration ceased, his jaw dropped, his eyes rolled upward, and to all appearances he was dead. His heart was beating very faintly, although his radial pulse was imperceptible. Although startled at this unlooked-for state of affairs, I began artificial respiration at once, and injected, in the absence of anything better, several hypodermics of an aromatic smelling-salts that chanced to be in the room. Later I injected, in two doses, a twelfth of a grain of sulphate of atropia. In addition to a sinapism over the heart, hot bottles and alcoholics, etc., were employed. Fifteen minutes after the catastrophe his pulse was about forty-eight, very feeble; respirations seven to eight; pupils *contracted*. Unconsciousness continued about twenty minutes. Afterward he convalesced nicely. Inferences from the above are obvious."

The Law and Professional Evidence.—A daily paper announces that Dr. J. A. Milne, of Oswego, N. Y., was on November 25th fined $250, with the alternative of six months' imprisonment, for contempt of court in refusing to testify in a criminal case. Dr. Milne pleaded as a defence for his refusal that his testimony would involve the disclosure of professional secrets. The law in New York, as well as in Arkansas, California, Indiana, Michigan, Iowa, Missouri, Minnesota, Montana, Ohio, and Wisconsin, is, that communications between physicians and patients which may relate to the history of a transaction in which a wound has been received, or a particular disease communicated, whenever essential to the treatment of a patient's case, are privileged. In New York it is even expressly enacted that the physician shall not disclose any information which he may have acquired in attending any patient in a professional character, and which information was necessary to enable him to treat the patient.

Cholera in Spain.—The cholera is reported to have disappeared entirely from Spain. No new cases are reported since about November 1st. The secretary of the National Board of Health gives as the total result of the cholera epidemic in Spain, up to October 21st, 273,549 cases, and 101,346 deaths, being a mortality of thirty-seven+per cent. In Italy, up to October 19th, there had been 1,370 cases (mostly in Palermo), and 627 deaths, being a mortality of fifty per cent.

Results of the Continuation of Pasteur's Inoculations for Rabies.—The Paris correspondent of *The Lancet* writes that the young shepherd (Jupille) referred to as being still under observation, and upon whom M. Pasteur has since ceased his inoculations, has returned to his native village. His room is now occupied by another lad of fourteen, who is said to have been bitten by a mad dog at Bordeaux. Two other children, also bitten by a mad dog, have been forwarded to Paris by the Mayor of Roubaix, to be subjected to M. Pasteur's treatment for hydrophobia. The persevering and zealous experimenter will soon have his hands full, and the confidence in his remedy is such that people come from great distances to consult him, without even taking the trouble to find out whether the dogs that bit them were really rabid or not; so that M. Pasteur will, under the circumstances, have some difficulty in selecting his cases. Owing to the favorable results obtained by M. Pasteur, it is proposed to organize a special staff in different localities for the carrying out of his method, and that all medical men should be instructed as to the manner of its employment.

The Power of Health Boards in the Matter of Vaccination in the Schools.—There has been some controversy at Lockport, N. Y., between the Board of Health and the Board of Education, in the matter of the vaccination of school-children. The Board of Health has, as we learn, insisted on the revaccination of school-children who have not been vaccinated for five years. The Board of Education has claimed that the law only compels school-children to be vaccinated once, and does not confer authority upon local health boards to interfere with attendance at school of children not revaccinated. The State Superintendent, Mr. Ruggles, has decided that the Board of Education is right in its position by virtue of the law of 1860, which, he thinks, was not repealed by the law of 1885, conferring power on the local Health Boards.

The Dangers of the Cocaine Habit.—Our caution with regard to the dangers of the cocaine habit has received an early illustration. It is announced that Dr. Charles D. Bradley, a Chicago physician, has become insane from the excessive use of this drug and that of morphine. It is stated that he became a slave to the drug, and made the most absurd claims about its powers. He declared that he was going to revolutionize medicine generally, and become the world's benefactor. In pursuit of his wild imaginings he mortgaged all his property, and his sick wife and invalid children are in absolute poverty. While before the judge he acted in a most eccentric way, calling on God to convince the judge and physicians that his theory was right. Dr. Wadsworth and Dr. Brower, who attended him, testified that they believed him insane from the use of cocaine and morphine, and thought he should be confined in an institution.

The Annual Meeting of the National Conference of State Boards of Health will be held in Washington at the same time that the American Public Health Association meets there, December 8th to 11th.

Virchow on the International Medical Congress.—At the anniversary meeting of the Berlin Medical Society, to which we made reference last week, Professor Virchow, in his address, said: "The larger we grow the more influential will this Society become, so that, at least for Berlin, it will prove that it is representative. We do not desire to be recognized as the representatives of all Germany, we do not wish to go beyond our own locality, but we desire to set an example, and to furnish strong testimony of that which we represent in our own proceedings. Of what may result when these aims are lost sight of we have at this moment a mournful example in America. You know your delegates to the International Medical Congress, held last year at Copenhagen, were instructed to invite the Congress to hold its next session at Berlin. We were outvoted, I am sorry to say, by the

co-operation of our German colleagues. The Congress decided to go to America. What is the result? A situation which at this moment makes it extremely dubious whether an International Congress in America is possible. While the individual societies of that country, to some extent like ours, consider science their shield and their defence, and have endeavored to create an organization in which the eminent representatives of American medicine shall also appear as the representatives of the coming Congress, the American Medical Association, a vast society of practising physicians, extending throughout the land, usurps the control of the organization of the next session of the Congress, and creates such confusion that, I am informed, verbally and by letter, no one at present is able to see his way out of the difficulty. Now, how did this dilemma originate? In the fact that the American Medical Association has set up a Code of Ethics, so called, and that with this code of professional ethics the admission to the Association is so broadly extended that entrance is free to all manner of dubious individuals. Hence has it resulted that, instead of eminence, mediocrity has come to the front, and that this Association, where the code is concerned, concerns itself more with forms than with principles. May I not then say that we are proud of our organization, by virtue of the care which we exercise in electing new members, and that we have, in this way especially, guarded against the necessity of forming a code of ethics, which every upright physician should in fact carry in his own bosom, and if he transgresses it he should be restrained both by the example and admonition of his colleagues? This has been our conviction, thus have we regarded the Association, so do we regard the great associations of physicians. With us, no necessity has been found to establish special codes or protective measures to secure us against the actions of dishonorable associates."

Typhoid Fever in Brooklyn has been unusually prevalent this fall. As regards the cause, a correspondent of *The Times* writes: "If you want a solution of the question why typhoid fever is so prevalent in Brooklyn, examine the drinking-water. Six years ago the city had clear water; no heavy rains then affected its cleanliness. Now, after every storm, the water is brown with dirt." He suggests that this indicates excessive surface drainage, which may cause and spread disease. He also directs attention to the graveyards that "surround the source of our water-supply."

Death of an old Physician.—Dr. Ephraim Clark, one of the oldest residents of Richmond County, N. Y., died November 20th, at the age of eighty-nine. For the past thirty years he was the County Physician, and a leader in the Democratic party, in Richmond County. He was the oldest practitioner on Staten Island, and was one of the physicians who attended Aaron Burr when he died.

An Expense Account Not Allowed.—A protest appears in one of the daily papers against the decision of the Treasury Department in the case of Dr. J. S. Billings. This officer was ordered by the Surgeon-General to visit the International Medical Congress in Copenhagen last year. The order was obeyed with a becoming disregard of personal convenience and with due concern for financial expenditure. Now the Treasury Department refuses to allow the bill for expenses.

Social Purity.—An association has been formed in this city which has for one of its objects "maintenance of the law of purity as equally binding upon men and women." One of the speakers at a recent meeting said that it was a matter of record that this State has expended more than $1,300,000 in supporting four generations of the descendants of one prostitute.

A New Disease of Editors in Kentucky.—Our invaluable contemporary, *The Medical Herald*, thinks that we are suffering from "cerebral ramblissment," and wishes us to "acknowledge our wrongs and enter the ranks of the American Medical Association." We would cheerfully concede the "ramblissment" if we knew what it was, for we should expect to be quite proud of having what is evidently a Kentucky disease. As for our "wrongs," we shall not acknowledge them on any account, considering it unmanly; but we are much obliged to the *Herald* for allowing their existence, and in return we wish to ask if it really thinks it is doing itself wrong to advocate the Old Code on one page and advertise the *British Journal of Homœopathy* on the next. Alas for *fames auri!*

The Practical Introduction of Nitrous Oxide and Oxygen as an Anæsthetic in Labor.—Some months ago Professor Zweifel, of Erlangen, erected the necessary apparatus for the supply of the mixed gases (nitrous oxide 80 and oxygen 20) to the accouchement ward of his obstetric clinic. He found it best to administer the gases continuously during the latter part of labor, when the pains were most severe—not, as was practised by Klikovich, merely giving the gases when signs of an approaching pain appeared. Though this treatment has been adopted in sixty cases, no retardation of the process was ever observed. The patients were generally semi-conscious; so that, though they would answer if asked a question, they felt no pain, and were unaware when the child was born. In one case, where the woman screamed as a stitch was put in the perineum, she afterward declared she had felt nothing. We see no special advantage in the use of these gases over chloroform.

The Academy of Medicine of Lima.—The opening session of the Academia Libre de Medicina was held in Lima, Peru, on July 29, 1885. In his inaugural address the president, Dr. Odriozola, sketched briefly the history of the formation of the society, recounting the labors, often apparently hopeless, of those who had toiled for eight months to accomplish this work, and congratulating them and the profession of Peru that at last their efforts had been crowned with success. The Academy opens with five sections—on medicine, surgery, biological science, public medicine, and natural and physical science.

Pensions to Physicians' Families.—The authorities of Saragossa have voted to grant an annual pension of 1,500 pesetas (about $300) to the family of every physician who died of cholera while in the discharge of his professional duties; and the hope is expressed that the officials of other cities and provinces will imitate their example.

Reports of Societies.

PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, November 6, 1885.

BEVERLEY ROBINSON, M.D., PRESIDENT, IN THE CHAIR.

DR. C. L. DANA described

A NEW URINARY REACTION AND TEST,

first suggested by Professor Ehrlich, of Berlin, as of value in the diagnosis and prognosis of certain febrile diseases

In 1882 Professor Ehrlich (in *Zeitschrift für klinische Medicin*, 1882; *Charité Annalen*, 1883) published his experiments with the diazor-compounds, as tests for aromatic bodies in the urine. When aniline (C_6H_7N), which is a nitrogenous body resembling an alkaloid, is mixed with nitrous acid, a series of peculiar bodies result known as the "diazor-compounds." These compounds have the property of uniting with a large series of bodies, chiefly of the aromatic group, forming colored compounds. Ehrlich prepared a saturated solution of sulfaniein acid in an acidulated solution of water. To this he added a little nitrous acid. The result was the production of a mixture containing diazor-compounds.

This mixture is added to the urine and the whole neutralized with ammonia, causing certain peculiar color reactions, which are, as Ehrlich believes, of value in the diagnosis and prognosis of certain febrile diseases.

Over two years ago I obtained some of the sulfaniein acid through Mr. Wm. Metenheimer, druggist, Sixth Avenue and Forty-fifth Street, and have been making use of the test ever since. I have tried it over one hundred times in all forms of disease. Through the kindness of Dr. Kinnicutt, and of Dr. Sherwin, late house-physician at St. Luke's Hospital, I obtained trials of it in a number of cases there. Through the house-physician of the Nursery and Child's Hospital, and through several of the visiting physicians of the Northeastern Dispensary, I obtained specimens for which I must express my acknowledgments.

At first my results were quite negative, and I wrote to Professor Ehrlich asking for explicit directions. He kindly answered me, sending on his own formulæ, which I have since used. Further errors were made, from the fact that the solutions soon spoil. I believe, however, that I have finally obtained enough facts to enable me to speak definitely about the test, and I present it to the Society as one that is of much interest, and, I believe, of considerable practical value to the physician.

The character of the test is indicated by the following summary of the diseases in which the reaction appears: (1) Never in the urine of the healthy; (2) never in the urine of the afebrile, except in rare instances of progressive heart-failure, chronic hepatitis, carcinoma, leukæmia, malarial cachexia, senile marasmus, cold abscess; (3) very rarely, indeed, it appears in rheumatism, meningitis, erysipelas; oftener, but still very rarely, in bad cases of pneumonia, scarlatina, diphtheria; (4) almost constantly in measles, typhus, typhoid, and very often in rapidly progressing phthisis.

The test, therefore, is of especial value in diagnosticating typhus or typhoid from malarial, tubercular, or syphilitic fevers, or in recognizing the appearance of a relapse of typhoid, in diagnosticating measles from rotheln or other eruptive fevers.

Various criticisms have been made upon this test. Most of these are favorable, but some are not. This contrariety I can readily understand, since the test requires one to have fresh and pure materials, and fresh specimens of urine.

Ehrlich repeated his tests about seven thousand times, as he states.

Fischer, of Berlin ("Dissertation," Berlin, 1883), repeated the test. He found in forty-eight cases of pneumonia that the reaction was present only nine times. In these cases there was some complication, and he concludes that the presence of the red coloring is a bad omen. He found the reaction in the eight cases of measles and three of typhus which he examined.

Brecht, of Berlin ("Dissertation," Berlin, 1883), applied the test in a large number of cases of diseases of various kinds, and his results confirm those of Ehrlich and Fischer.

J. Georgiewsky, of St. Petersburg (*Deutsche Medicinische Wochenschrift*, No. 48, 1883), applied the test in fifty healthy cases with no result. He also tested in a large number of cases of various forms of afebrile disease, and obtained the reaction only once, in a case of bronchitis and emphysema with slight fever. He found the reaction in all cases in typhoid fever, in one complicated case of pneumonia, and one fatal case of pneumonia with gangrene. He tested it in one hundred cases of phthisis, and found that there was some relation between the progress of the disease and the presence of the red reaction, as Ehrlich claimed.

F. Penzoldt, of Erlangen (*Berlin. klinische Woch.*, 1883, No. 14), denies the value of the test, as a result of one hundred and thirty trials. To a statement by Ehrlich that he did not use the test correctly, Penzoldt has replied (*Berlin. klin. Woch.*, 1883, No. 49).

Escherich, of Wurzburg (*Deutsch. Med. Wochenschr.*, 1883, No. 45), has repeated Ehrlich's experiments, and confirms his results.

The subject was discussed before the Berlin Society of Internal Medicine, June 16, 1884, the views expressed being generally antagonistic to those of Ehrlich.

Finally, Ehrlich reiterates his views, and presents his latest conclusions in the *Deutsch. Med. Woch.*, 1884, No. 27.

The method of applying the test is as follows:

Three solutions are made.

SOLUTION A.

℞. Aquæ	100.
Acid. muriat. conc.	5.
Sulfanilin acid,[1] q. s. ad saturation.	
M. Sig.—Sol. A.	

SOLUTION B.

℞. Sodii nitrit	0.1
Aquæ	20.0
M. Sig.—Sol. B.	

SOLUTION C.

℞. Sol. A	50.
Sol. B	1.2
M. Sig.—Mixture for use.	

Solutions A and B keep for some time in cold weather; solution C, or the mixture, does not keep well, and should be made fresh every time it is to be used. It is safer, I find, to have solutions A and B fresh also. The nitrite solution at least appears to decompose very quickly.

To make the test, take a test-tube one-third full of the suspected urine, add an equal amount of the mixture C. This causes a slight yellow discoloration. Then add a little stronger aqua ammonia sufficient to alkalinize the solution (℥ j.–℥ ij.). This causes in normal and afebrile urine a beautiful reddish color, in which, after standing twenty four hours a deposit (of phosphates) is seen which is of a natural light-gray color.

If *the urine presents the diazor-benzol* reaction as in the class of cases indicated, then, after adding the mixture C, the color is a darker one having a purplish tinge. After standing twenty-four hours, there is a deposit of phosphates *colored a dark olive-green*. This colored deposit I have only seen in typhoid fever, measles, and once in a badly complicated case of pneumonia. I have never found it in scarlatina, phthisis, or any afebrile urine. The presence of albumen or sugar does not affect the

[1] This can probably be obtained through Mr. Metenheimer, Sixth Avenue and Forty-fifth Street, New York City.

test. The test is a simple one, and can be applied in a very short time when the materials are at hand.

THE LOCAL TREATMENT OF CHRONIC DYSENTERY.

The discussion was opened by DR. CHARLES S. WARD, who said: Briefly, as a text, I wish to bring more prominently before the Society the treatment of chronic dysentery, locally, as proposed by Dr. Maury, of Memphis. Starting with the clinical fact that such cases as we recognize as chronic dysentery are due to lesions which exhibit themselves predominantly in the lowest part of the large intestine, we are enabled to treat them efficiently, and for the most part effectually, by local applications.

The method, so well known and practised, consists in first thoroughly emptying the bowel by a saline, then anæsthetizing the patient, preferably by nitrous oxide gas, the patient being in the Sims position; the sphincter ani is thoroughly paralyzed after the manner of Metcalfe, a Sims speculum introduced, which, if properly used will allow a view of the entire rectum, exposing every point of ulceration, to which applications of nitric acid may freely be made by a rod with its end wrapped with cotton and dipped into the acid. It is essential that the acid be freely used, and any excess afterward neutralized by a solution of bicarbonate of soda brushed over the rectum before withdrawing the speculum. My uniform experience in a large number of cases leads me to expect that there will be no action of the bowel for twelve or fifteen, and even thirty-six hours after the application, and whereas it may be argued that applications to the rectum alone cannot possibly reach ulcerations which almost invariably exist above, I must answer that either the anæsthesia produced by the application allows time to heal them, or the relief following the subsidence of tenesmus permits the bowel above to regain, in some measure, and to maintain, a normal peristalsis, thus favoring a return to a healthy action and normal state of the bowel as a result.

My experience leads me to expect, during the exfoliation resulting from the caustic application, which occurs from the second to the fifth day, that there will be a number of actions of the bowel, which, however, will be more natural in character. At the end of ten days it may be necessary to repeat the application of the nitric acid. There are cases, not many, however, which require more applications. Of course, the diet should be rigidly a milk diet.

I have spoken only of nitric acid, for I believe it far excels all other applications; in my experience it is far superior to solutions of the argentic nitrate, being less painful and more efficient. Properly applied, no slough should result, rather an exfoliation, followed by a normal development of epithelium over the entire mucous membrane.

To sum up: Astringent and narcotic remedies by the mouth avail but little.

Proper cleansing of the rectal mucous membrane and direct applications to the entire rectal wall, as well as to the ulcerations, tends to rapid and permanent cure.

Opiates are of service for a few hours after the applications; they should be given by the mouth or hypodermatically, as the rectum after such applications fails to absorb.

DR. JAMES B. HUNTER said he had but little to add to what Dr. Ward had already said. He assisted in the first case in which Dr. Thomas made use of this method of treatment, and it was when Dr. Maury was present, probably eight or nine years ago. The patient had been suffering for several years, and the examination, after dilating the sphincter, showed numerous ulcers, which were touched with nitric acid. No other treatment was adopted and the patient was quickly cured. After that he assisted Dr. Thomas in treating several cases, and had also treated several cases of his own. He had regarded the method as applicable to those cases in which ulcers were within reach.

He had used nitrate of silver, but the effects were not so satisfactory, and it gave the patient a good deal of pain. After the use of nitric acid the pain had been, in the cases in which he had seen it applied, only very slight.

The ulcers, in the cases in which he had seen it used, had apparently been within three or four inches of the verge of the anus. There may have been ulcers high up, but they were chiefly confined to the lower part of the bowel.

DR. PEABODY said the method was important, but he thought it was one for treating ulcers of the rectum rather than chronic dysentery. It had been claimed that the application of caustics to the lower ulcers had a tendency to heal the upper ones. If that could be substantiated it would be a matter of very great interest.

DR. G. F. SHRADY said he was unable, in the first place, to see how it could be proved that ulcers existed higher up, when necessarily out of sight, and, in the second place, that they were cured. Neither of these possibilities could be demonstrated except by an autopsy.

DR. A. A. SMITH said the subject was one of special interest to him, because in the autumn of 1872 he spent two months with the late Dr. Lente at Cold Spring, where he had opportunity to test this method of treatment with the most marked success. Dr. Lente's plan was to dilate the sphincter, introduce the speculum, wash out the rectum, find every spot of ulceration and touch it with nitric acid, and immediately apply a strong solution of bicarbonate of soda. For that reason it was a matter of considerable interest to know the exact time when Dr. Maury began this method of treatment. It seemed to Dr. Smith a matter of a great deal of importance that the effect of the nitric acid should be neutralized very quickly, because of the liability to produce a condition which might be followed by stricture. The plan which he had followed had been to touch the ulcer with nitric acid, and then as quickly as possible to syringe upon the part a strong solution of an alkali, usually bicarbonate of soda.

DR. HUNTER said that when he first began to use this treatment he was very much afraid of the occurrence of stricture; but he had taken pains to inquire of the patients several years afterward, and had learned that no such result had followed.

DR. SMITH said that latterly he had applied the acid to only one or two ulcers at the same time.

DR. PEABODY said there was no question but that ulcers existed above ordinary reach—indeed, very high up—with chronic dysentery. It was also unquestionably true that the ulcers which produced the most marked symptoms were situated low down. Ulcers of the intestines as such, whether large or small, produced no symptoms, as extensive ulceration of the small intestine might occur without any symptoms whatever being produced by it. The same thing might be true of ulcers in the *upper part* of the large intestine, but with regard to ulcers in the *lower part* of the large intestine it did not hold good.

DR. W. M. POLK said that when Dr. Thomas published his pamphlet, giving an account of this method of treatment—which, by the way, was an old one—the observations had been made in those cases of chronic dysentery where the difficulty was located in the rectum, and could be reached, and for that class of cases he regarded it as the best method which could be adopted; but in the large proportion of cases the ulcers extended above, and could not be reached. The method of applying the acid was to dilate the sphincter, and introduce a Sims speculum.

In connection with this subject, he would make mention of the local application of cocaine, to which his attention had been directed by Dr. Joseph E. Winters, who had used a four per cent. solution in a case of acute dysentery occurring in a child, and with very satisfactory results. The application was made through a speculum, and in a case in which all other remedies for the relief of tenesmus had failed.

DR. KINNICUTT had used a four per cent. solution of

cocaine in one case of dysentery with moderate tenesmus, making applications with a camel's-hair brush just within the rectum; the relief of the pain was very great.

Dr. Hunter recalled a case in which he used the Paquelin cautery in the treatment of ulcers of the rectum, but the result was not at all satisfactory, and afterward he cured the same patient by the local application of nitric acid.

Dr. C. L. Dana directed attention to the internal use of naphthalin, which he had used in one case only, but with a good result. He began with five-grain doses, quickly increasing it to fifteen-grain doses. A single full dose of the remedy would disinfect the fæces for twenty-four hours, and he thought it possible it might prove to be of service in the treatment of chronic diarrhœa and dysentery.

Dr. Gibney had given bismuth in drachm doses every two hours for twelve hours, with permanent relief, in at least half a dozen cases which had resisted other treatment.

Dr. Smith suggested that naphthalin be combined with the bismuth in order to correct the intolerable odor following the use of the latter remedy.

Dr. Cleveland referred to three cases of chronic diarrhœa which got well under the use of castor-oil, a drachm night and morning, administered preferably in capsule. These cases had resisted other forms of treatment. The use of the oil was persisted in for several weeks. The effect was, for the first three or four days to make the passages more frequent, but afterward the passages were almost normal.

The President read statistics gathered for him by Dr. E. B. Dench, Jun. Asst. in St. Luke's Hospital. From 1875 to 1885, the total number of cases of diarrhœa and dysentery, treated by local applications of different kinds, was *twenty-five;* acute dysentery, *nine*—four cured, two temporarily improved, and three unimproved; chronic diarrhœa, *nine*—five cured, four unimproved, one dying of pulmonary disease, three cured by internal medication; chronic dysentery, *seven*—two cured, three improved, one temporarily improved (died of perforating ulcer), one improved (improved by internal medication).

The Society then adjourned.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN OBSTETRICS AND THE DISEASES OF CHILDREN.

Stated Meeting, November 25, 1885.

Alexander S. Hunter, M.D., Chairman.

Dr. Joseph E. Winters read a paper on diphtheria (see page 617).

DISCUSSION ON THE TREATMENT OF DIPHTHERIA.

Dr. W. H. Thomson was requested to open the discussion, and said he had been very much interested in the paper, as every practitioner must be who had seen much of this exceedingly formidable disease. As each speaker had but ten minutes in which to express his opinions, he would beg to differ from Dr. Winters in some points at the outset. The author might comfort himself, in not having convinced all of his auditors of the correctness of his views, with the fact that, regarding diphtheria and croup, there were scarcely two physicians who thought alike. First, he should differ from him *in toto* on the subject of the elimination of the poison of diphtheria. We should not expect, for example, that a field would eliminate wheat which was growing in its soil; we should expect, on the contrary, that it would give the wheat opportunity to grow. In any disease which is propagated in the following way, namely, by the introduction into the system of a small quantity of a morbific germ or agent, which is followed by a period of latency, during which time no one knows what is taking place; then by a period of development and reproduction corresponding to three great facts seen in nature, that is, germination, development, and reproduction; he could not see how in such a case the system was going to be liberated of the morbific agent by elimination through the skin, kidneys, or other excretory organs. The skin cannot be expected to eliminate the disease in the case of small-pox, for it is itself the seat of lesions occurring in the course of the disease; the kidneys cannot be expected to eliminate the poison of scarlet fever, as they themselves are often the soil in which the disease manifests itself; nor could he understand why we should expect in diphtheria, which is an analogous affection, being a communicable disease, to eliminate the poison by means of the skin, kidneys, or alimentary canal. Therefore, in starting out to select measures for counteracting this formidable complaint, he freed his brain completely of all thought of a medicine which would have the power to eliminate the diphtheritic poison. But what we might do, if we saw the case early enough, and thus have time, was to eliminate or prevent the occurrence of some of the secondary results of the diphtheritic process. While he did not think the bowels, the kidneys, or the skin carried off anything of the diphtheritic poison, he would freely admit that in febrile diseases generally, diphtheria included, a formidable complication consisted in the arrest of gland secretion in all parts of the body. Whenever fever occurred, it at once caused suspension of the secretions of the alimentary canal, and of the excretions in various parts of the body, and wherever arrest of the natural excretions took place for twenty-four or forty-eight hours, the patient must suffer more or less from this accumulation of poisons in the system. Now the germ of diphtheria—meaning by the term germ a seed which reproduced itself—found a better soil for development in blood which was poisoned by retained excretions. He therefore always administered at the beginning of febrile diseases, notably scarlet fever and typhoid fever, a medicine which would keep the bowels in their usual state of activity, and not more.

Regarding other indications in the treatment of diphtheria, the first was, as far as possible, to prevent the depressing effects of the specific poison. Here he uses the term specific poison advisedly, meaning thereby the poison generated by the growth of the diphtheritic material. That poison had the same relation to the diphtheritic material that the poison of septicæmia has to the bacteria which occasions pyæmia. The bacteria which causes pyæmia is a living thing, which reproduces itself, and can be introduced on the lancet and made to affect the system. Septicæmia, on the other hand, is due to a poison generated by this, and can be separated from it. So in diphtheria we have a poison generated in the local necrotic process of diphtheria, which is very dangerous, which is paralyzing to the nervous system, and particularly to the muscular tissue of the heart. He believed, therefore, in the use of antiseptics, among which the muriate tincture of iron takes a high rank, as do other preparations of iron. The muriate tincture is an antiseptic for two reasons: first, because it carries chlorine, and, second, because it brings oxygen into the system. The disinfectant properties of chlorine may be further obtained by the use of Labarraque's solution and generating chlorine gas in the room.

Another feature in the treatment was the use of alcohol, which should be administered at the time of feeding, usually with milk. To wash out the throat with a solution of chlorate of potash would give the child much relief by softening the exudation and increasing the secretion of mucus, enabling the child to expectorate easily.

The Chairman thought the amount of the tincture of iron which the author of the paper had used was very great, and he asked Dr. Thomson in what doses he would recommend its use.

Dr. Thomson replied that the doses which had been mentioned by Dr. Winters were larger than he had ever administered, and larger than he would have considered

safe, but the author of the paper had presented facts, and facts must outweigh opinion.

Dr. John C. Peters agreed in the main with Dr. Thomson, but he had always looked upon diphtheria as a local affection. The starting-point was in the throat, and if the blood became affected it was secondary, and arose from the progress of the affection in the throat. Consequently he had always been exceedingly careful, before allowing the child to eat or drink, to have the throat well syringed with chlorate of potash or water. He had thus seen the throat kept clean and free from offensive odors. If it were not kept clean there would be danger of secondary infection. He agreed with Dr. Thomson on the point of elimination of the poison. He also believed in the administration of a laxative at the beginning of the disease, for in almost all acute diseases the last meal was not thoroughly digested. He believed in the use of bichloride of mercury as a disinfectant. A small quantity might be used for washing out the throat, and for internal administration the powder should be placed upon the tongue, thus getting its full benefit. His main treatment was local, and he did not believe in pouring medicines down into the stomach with the hope of curing the throat affection. He was opposed to removing the membrane or applying any harsh measures to the throat. As to poultices, he would object to their use decidedly, for once begun they must be continued, thus rendering the throat tender, and doing more mischief than good. A flannel covered with oiled silk would protect the throat, and cause enough sweating. He believed with Dr. Winters in the disinfecting properties of sulphur, but he had greater faith in turpentine, which he had sprinkled on the floor and furniture, and caused the vapor to fill the rooms. He agreed with Dr. Winters also in the opinion that in the large majority of cases the disease did not involve the lungs. By simple and proper management a large proportion of the cases would not end fatally.

Dr. Fowler said that from what he had seen of croup and diphtheria he regarded them as distinct diseases. If the case were one of croup, there being no apparent implication of the fauces, his treatment was calomel, small doses frequently repeated, and alcohol.

As to throat symptoms in diphtheria, if they were extreme, he would always apply ice, from which he had obtained great satisfaction. Ice locally, muriated tincture of iron, in thirty-drop doses every half-hour, and plenty of alcohol, even to the extent of intoxication if there were great exhaustion, seemed to be required.

Dr. W. E. Forest said that one practising medicine in the lower part of the city was apt to see a good deal of diphtheria, and probably would try almost every mode of treatment. According to his experience, the only successful way to manage diphtheria was to treat it vigorously as a local disease. If the case were seen early, and vigorous local treatment adopted, the disease could almost certainly be controlled. The local treatment should be astringent, for the purpose of preventing the development and absorption of the germs of the disease, and in addition to that, supporting measures. If the general system has become thoroughly affected before the child is seen, recovery will depend, in the first place, upon the natural strength of the child to resist the influence of the poison, and, secondly, upon the amount of support which can be given by iron and brandy, and then upon what benefit local treatment will give.

Dr. J. Blake White believed croup and diphtheria were two distinct diseases, the first-named being at the beginning sthenic, the second asthenic, in character. He believed in the use of large doses of iron in diphtheria, and of large doses of calomel, say two doses of ten grains, in croup. A gargle of turpentine and milk, fifteen to thirty drops of the spirits of turpentine in half an ounce of milk, every half hour to two hours, was of benefit in diphtheria. Some good came from the use of antipyrine as a febrifuge. With regard to the question of elimination of the poison, he was inclined to agree with Dr. Winters.

Dr. Billington said his views on this question were generally known, but he wished to thank Dr. Winters for the thorough manner in which he condemned the abuse of mercury. In dealing with a formidable disease, it was a most important duty on the part of the physician not to make himself a source of danger to the patient. He agreed with Dr. Peters that the disease primarily was local; it mattered not where it began, whether in the throat or on the abraded skin, and from that local point the poison was absorbed and carried into the general circulation. It made a great difference usually in the plan of treatment which one was likely to adopt as to whether he regarded diphtheria as primarily a local or a constitutional affection. Looking upon it as he did, he thought the proper treatment was to attack it locally. Several years ago he advocated local syringing with simple salt and water, frequently repeated.

Dr. L. E. Holt had seen three cases the past year in which the disease had extended down the larynx and caused death from obstruction. With regard to local treatment, it was a very easy thing to order that the throat be swabbed frequently with an antiseptic solution, but it was quite a difficult thing to do. It had been stated this evening that if we did no good we should do no harm. Dr. Holt thought that here we would do actual harm because of the resistance offered to the treatment, and the ineffectual manner in which it would be carried out. He thought that in children under four years of age we must rely almost entirely upon constitutional treatment. As to treatment by bichloride of mercury, he had employed it, but had not seen any good effects from it whatever. To be sure, the cases in which he used it were severe ones, but if the remedy was to prove of any benefit it should stand the test in severe cases. Dr. Holt favored the tincture of chloride of iron in large doses, above all other remedies. If given frequently, it acted as an astringent and antiseptic. He had never seen it used in so large doses as had been mentioned by Dr. Winters. He also used alcohol in large doses, and adopted supporting measures from the beginning.

Dr. S. W. Smith agreed with the author in the view that diphtheria and croup were one disease. He gave illustrative cases. As to treatment, it was necessary, in order to test a given course of treatment thoroughly, to carry it out strictly in a number of cases. Believing that the disease was a local affection with a constitutional expression, Dr. Smith had employed the tincture of the chloride of iron and chlorate of potash alternately, and syringed the throat with salt and biborate of soda. In thirty cases so treated he had not seen any indication for the use of alcohol, antipyrine, or any so-called antipyretic. The diet had consisted of milk.

ARE DIPHTHERIA AND CROUP DISTINCT DISEASES?

Dr. Delafield was requested to open the discussion on the above question, and said: In attempting to discuss this question we are met at the outset with difficulty in determining exactly what is meant by croup and diphtheria. All are pretty well agreed that diphtheria is an infectious disease, but when it comes to croup, we find that the word is used in rather an arbitrary way. I think some of you must have noticed this in listening to the speakers this evening. Sometimes the term membranous croup is used as if it meant a distinct disease; at other times as if it meant simply a local inflammation, and these are two different things. If when we say membranous croup we simply mean that a child or grown person has an inflammation of the larynx of a certain anatomical type, as a croupous laryngitis, I think we must all admit that it is perfectly possible to have such a croupous laryngitis without any diphtheria at all.

In the first place, with regard to the lesion of diphtheria. Is there anything specific in it, or have we any reason to expect that there should be anything specific about it?

To both of these questions I should unhesitatingly answer, No. The lesion of diphtheria is nothing but an inflammation of a special anatomical type, and inflammations of exactly the same anatomical type can be excited in mucous membranes by a variety of means. There is nothing specific about it. It is simply that this special disease, diphtheria, is regularly accompanied by a characteristic local lesion, and we can excite an identical inflammation at will by experimental means. So I think we can say without question that diphtheria has a characteristic local lesion, but it has not a specific lesion. Still further than this, I do not see why we should expect that it would have a specific lesion. I think we should expect the same thing in diphtheria as we do in other infectious diseases. We know that in epidemic cerebro-spinal meningitis, and in meningitis from fracture of the skull, the inflammatory lesion is the same, although the cause of the meningitis is different in the two cases. It seems to me a matter of some importance when we think of lesions of the larynx that we should also think of lesions of other mucous membranes throughout the body. The mouth, the throat, the larynx, the trachea, the bronchi, the stomach, the small and large intestines, and the bladder, comprise the more important tracts of mucous membrane. What do we find with regard to each one of these? We find that they are specially liable to become the seat of catarrhal inflammation, and that they are comparatively rarely the seat of croupous inflammation; and yet they are all capable of being the seat of croupous inflammation as well as of catarrhal inflammation. But when we come to the mucous membrane of the colon we find that it is more liable than any other to take on croupous inflammation. It is, then, simply in accordance with our ordinary experience that while in New York the great majority of cases of croupous laryngitis belong to diphtheria, and simply represent the characteristic lesion of diphtheria, yet it seems to me equally certain that we may have a croupous laryngitis which has nothing to do with diphtheria at all. Of course, no one doubts such traumatic croupous laryngitis from inhalation of hot steam or smoke, or the swallowing of boiling water; but I think we should admit that it is possible to have croupous laryngitis from what we call exposure to cold or atmospheric influences; in all cases the lesion being the same, but due to a different cause.

Dr. W. H. Thomson thought that the descriptions given of membranous croup by Cullen, and other English and American authors, pointed very distinctly to a disease which was much more common up to about 1826 than it has been since, and which was quite different from diphtheria, of which we see so much at present. It seemed to him that there was no mistaking the description of the disease as given by those acute observers. The impression which he had received from reading their works was that croup was of common occurrence, while diphtheria formerly was a rare affection in New York, visiting the city perhaps at intervals of thirty or forty years, just as now we have here and there an epidemic of cerebro-spinal meningitis. These facts had an important bearing upon the question as to whether diphtheria and croup were distinct diseases. At present we saw croupous laryngitis very seldom except as associated with diphtheria, but formerly diphtheria was a rare complaint, while croup occurred relatively frequently, and independent of diphtheria. Dr. Thomson mentioned one fact in which his experience differed from that of the author of the paper. He had seen at least three cases in which there was nasal diphtheria without involvement of the larynx, and he was inclined to think that nasal diphtheria occurred more frequently than was generally supposed, but it might be overlooked.

Dr. Henry R. Baldwin, of New Jersey, by invitation, said that in the course of many years' practice he had frequently seen membranous croup without any exudation upon the fauces. Again there was, about 1840, an epidemic called putrid sore throat, in which there was swelling of the tonsils with rapid septicæmia and death, but there was no mention of any exudation taking place in the trachea or larynx. There was an epidemic of diphtheria in Plainfield about 1864, during which no lesion occurred in the trachea, and there was no thought of the disease being croup. His experience agreed with the view entertained by Dr. Thomson, that formerly diphtheria occurred rarely, while croup was of frequent occurrence.

Some facts which seemed to him to have a bearing on the duality of croup and diphtheria were the following: First, according to his experience, the edge of the wound after tracheotomy did not become the seat of exudation; second, that in diphtheritic inflammation the mucous membranes were prone to hemorrhage, while there was no such tendency in croup; third, that in membranous croup death took place not from toxæmia, save from want of oxidation in the blood, while in diphtheria the toxic effect of the disease was liable to prove fatal. One's view with regard to the question as to whether diphtheria and croup were distinct diseases, would also be likely to have an important bearing upon the treatment; those who supposed diphtheria to be a distinct disease of an asthenic nature would be likely to adopt a supporting treatment and employ alcohol, etc.

As to antiseptic treatment, he found benefit from a mixture of salicylic acid and glycerine, painted over the fauces.

Dr. Winters, in closing the discussion, said that Dr. Thomson, in comparing the elimination of the diphtheritic poison to the elimination of a mineral poison, as arsenic, went contrary to his teachings in the University Medical College, where he always made a distinction between the nature of poisons, according to whether they were mineral, a form of plant, or animal, etc.

Dr. Thomson explained that it was not his intention to make such a comparison between the action of the poison of diphtheria and a mineral poison. He had said that he would as soon expect a field to eliminate the wheat which grew upon it, as that the human system should eliminate a poison which was capable of reproducing itself, like that of diphtheria, scarlet fever, etc.

Dr. Winters replied that there was no analogy between the action of the poison of a specific disease in the human system, and the growth of wheat in a field, and no comparison could be made in the matter of elimination in the two cases; for, in the one, the process was one of growth, while in the other, it was one of decay. Now, in scarlet fever, the poison was evidently being eliminated with the excretions, as they were capable of conveying the disease to the unaffected. With regard to the large doses of the tincture of the chloride of iron, they were in the habit, at the dispensary, of giving half-drachm doses hourly, and frequently two-drachm doses hourly, and in some instances two drachms half hourly, and there were several gentlemen who had seen the cases who could testify to the remarkably good results of the treatment adopted.

With regard to croup having prevailed here in past years, according to his reading, the cases which had been described corresponded clearly to diphtheria, and did not at all go to show the duality of the diseases.

With regard to the remarks made by Dr. Delafield, Dr. Winters asked whether we could compare an inflammatory process, excited in a mucous membrane by a cold, and which might extend over months, but which never terminated in the formation of a pseudo-membrane, to what is commonly understood by a croupous laryngitis? Again, there was no case on record in which a membranous inflammation of the larynx, produced by the action of steam or chemical irritants, extended down the air-passages.

Dr. Delafield—I have a specimen now.

Dr. Winters said he had examined the records thoroughly and had not found any such case, and it is stated in one of the volumes of the *British Medical*

Journal that no such case is on record. Dr. Winters also replied to some other points raised in the discussion, but which had received attention in the paper.

The Section then adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

MEDICAL SOCIETY OF LONDON—DISCUSSION ON THE DEEP REFLEXES AND THEIR CLINICAL SIGNIFICANCE—THE OPERATIVE TREATMENT OF TOTAL SUPPRESSION OF URINE—THE DEAD-LOCK AT THE COLLEGE OF SURGEONS—SCARLATINAL ALBUMINURIA AND THE SO-CALLED PREALBUMINURIC STAGE—THE WORKING OF THE CONJOINT SCHEME—A NEW UNIVERSITY FOR LONDON—THE LATE DR. W. B. CARPENTER.

LONDON, November 7, 1885.

AN important discussion on the deep reflexes and their clinical significance took place recently at the Medical Society of London. The discussion was opened by Dr. Gowers, physician to University College Hospital, who is well known as an ardent inquirer in the domains of neurology.

It has been recognized that tension on a muscle is an essential condition for the production of the phenomena in question. Dr. Gowers believes that this tension stimulates the afferent nerve fibres, and that this stimulation so influences the centres in the cord as to induce in the muscular fibres a state of slight contraction, probably the same as the physiological "tonus." In this condition local mechanical stimulation causes a sudden brief contraction. A tap on the tendon causes a sudden increase of tension, and the latter is one form of mechanical stimulation. If increased tension be maintained, the muscle, when relaxing from the first contraction, is excited to another, and so a clonus occurs. The contraction is local. The irritability is reflex, and, as it is excited by tension, Dr. Gowers prefers to call it "myotatic irritability." The muscle-reflex centres, he thinks, overact from a loss of the normal control, probably exerted by structures in the gray matter of the cord at the same level. Dr. Gowers maintains that this hypothesis enables us to explain the condition of the deep reflexes in ether- and chloroform-narcosis, and after epileptic fits. Coming next to the practical application of these phenomena, Dr. Gowers spoke first of locomotor ataxia. He believes that most instances of the alleged absence of the knee-jerk in health have been due to imperfect observation, and that its absence is of great significance as an indication of impending ataxia. The presence of the knee-jerk, though, does not, he remarked, exclude true tabes. Diphtheritic paralysis is another condition in which it is absent, and Dr. Gowers quoted Bernhardt's observation, that the loss may follow diphtheria when there has been no paralysis. If incoördination be also present, an erroneous diagnosis of tabes may be formed. In pseudo-hypertrophic paralysis the knee-jerk is ultimately lost (probably, said Dr. Gowers, from the morbid process occupying the interstitial tissue in which the afferent nerves of muscle end), a symptom of great diagnostic importance, as it distinguishes the disease from slight congenital spastic paraplegia, in which latter affection the knee-jerk is always increased. The condition of the deep reflexes in hysterical paraplegia was discussed at some length. While not denying that a true uniform clonus, such as occurs in spastic paraplegia, may occur in hysterical paraplegia, Dr. Gowers is of opinion that it is so rare that it does not lessen the value of this sign of organic disease. He believes that some cases which have been cited as cases of hysterical paraplegia have really been cases of organic disease. We must not forget, he said, that true spastic paraplegia may be recovered from. The wide use of the term "functional disease" was then referred to. Dr. Gowers thinks that in many cases so described there is a change in the nutrition of the nerve elements, and this, springing perhaps from functional derangement, maintains and increases that derangement. "Functional diseases" he considers better described as "nutritional diseases." In cases of hysterical paraplegia in which there is a persistent change in myotatic irrita, bility, there must be a change in the nutrition of the cord, and Dr. Gowers remarked that a case recorded by Charcot seems clearly to prove that a paraplegia, purely hysterical at first, may pass on into lateral sclerosis.

Dr. Hughlings Jackson then spoke. He referred to his own hypothesis that increased knee-jerk and foot-clonus, in cases of hemiplegia from destructive cerebral lesion, were owing to loss of cerebral control. He seemed disposed to accept, in addition, Dr. Gowers' theory of local spinal inhibitory centres. The current hypothesis, said Dr. Jackson, will not account for increased knee-jerk and foot-clonus in some cases of post-epileptiform paralysis. Dr. Jackson said the condition of the deep reflexes after epileptic fits was a matter of serious import in the analysis of the wide symptomatology of epilepsy. Foot-clonus after epileptic fits was, he thought, an illustration of the principle of "loss of control" enunciated some years ago by the late Dr. Anstie.

Dr. Buzzard expressed his concurrence with Dr. Gowers in considering absence of the knee-jerk as being always pathological. Its apparent absence in many cases he considered explicable by imperfect methods of examination, and referred to some more exact methods of determination brought forward by himself and others. Absence of knee-jerk, occurring in the course of acute or subacute disease, may, he said, be due to anterior poliomyelitis, diffuse myelitis, neuritis, or spinal meningitis involving the anterior or posterior roots, or both. He had never known it lost as the result of hysteria. It was very commonly absent in the form of multiple neuritis which was apt to follow diphtheria. The knee-jerk was often lost for many hours in severe cases of cerebral hemorrhage, and perhaps also in thrombosis. Its loss pointed to the case being grave. The return of a lost knee-jerk in cases of poliomyelitis, diffuse myelitis, neuritis, and spinal meningitis was of favorable import. Dr. Buzzard said that the knee-reflex when lost in tabes dorsalis was not, in his experience, regained. Bouchard found it absent in nineteen out of sixty-six cases of diabetes mellitus, and Dr. Buzzard has found it absent in three cases of that disease. Excess of deep reflexes signifies that the inhibitory influence of the higher centres is no longer being normally excited. In Dr. Buzzard's experience, the greatest excess is to be found in cases of compressive lesion of the cord, as from Pott's disease. Caries of the lower dorsal vertebræ, however, would probably lead to total absence of knee-jerk from disorganization of the cord in the lumbar enlargement. Excess of reflex and ankle-clonus occurring in the course of spastic paraplegia of apparently protopathic origin was permanent, and the prognosis of such cases extremely bad. But if secondary to a localized lesion in the cord they might disappear, and the power of the limbs return. Ankle-clonus and, at the same time, total absence of knee-jerk in a limb often pointed to disseminated sclerosis. Dr. Buzzard said that, in his experience, the occurrence of true ankle-clonus, while always suggestive of organic disease, was not a proof of it. He had seen ankle-clonus (indistinguishable from that of lateral sclerosis) in many cases of hysterical paraplegia in which, on recovery, it disappeared. Exaggerated supinator reflex occurring a month or two after a hemiplegic seizure was, he remarked, of very bad prognosis as regards recovery of power; occurring in the course of epileptiform seizures, it had by no means the same importance.

Dr. Althaus referred to the frequency and importance of the absence of the light reflex in locomotor ataxia as an additional diagnostic feature of that affection, and de-

scribed two cases at some length. In these Dr. Althaus maintained that the pupillary symptoms showed that locomotor ataxia was not simply a disease of the posterior columns of the cord. He then went on to speak of the exaggeration of the deep reflexes in tetany. This consisted of a succession of attacks of tonic spasm or rigidity invading certain groups of muscles, especially the flexors of the hands and arms, followed by free intervals, and unaccompanied by loss of consciousness. The diagnosis of this affection was not always easy. In general, Trousseau's symptom (the production of spasm by compression of the limbs) was relied on, but a readier test was the behavior of the deep reflexes—more especially of the portio dura. A slight tap in the neighborhood of the stylo-mastoid foramen would cause all the facial muscles on that side to contract. Dr. Althaus said he distinguished three types of exaggerated reflexes, viz.: the cerebral, the spinal, and the muscular. In the cerebral type the response was quick and very extensive, so that the leg was thrown forward a considerable way. This type occurred in various lesions of the brain, particularly softening and tumor; also in some cases of epilepsy, and in most cases of hemiplegia from hemorrhage into the corpus striatum, or embolism of the middle cerebral artery. The spinal type was distinguished by an exceedingly quick and jerky motion of the leg, not nearly so extensive as in the cerebral type. Exaggerated reflexes of this type were seen in some forms of spastic spinal paralysis, of insular sclerosis, in certain combined system diseases of the spinal cord, and also in persons injured in railway accidents. Dr. Althaus remarked, in conclusion, that an excessive exaggeration of the deep reflexes in the palsied limbs in hemiplegia, with normal reflexes on the other side, pointed to a syphilitic origin of the affection.

The discussion then terminated, Dr. Angel Money's paper being taken as read, owing to the lateness of the hour.

A case of total suppression of urine has lately been successfully treated by operation at Guy's Hospital. The patient was a woman, from whom Mr. Clement Lucas successfully removed the right kidney about four months ago. The secreting structure of the organ removed was found to be totally destroyed by large calculi and hydronephrosis. After a complete recovery she was suddenly seized, about a fortnight ago, with pain in the region of the left kidney, which was quickly followed by suppression of urine, headache, and vomiting. She was brought to London, and again admitted into Guy's Hospital. After diuretics had been tried without benefit, the patient becoming more weak and drowsy, Mr. Lucas cut down on the kidney and removed a conical stone from its pelvis. A free flow of urine took place through the wound, the vomiting and drowsiness ceased, and by the last accounts the patient is doing well.

London, November 13, 1885.

The controversy between the Members and Fellows of the College of Surgeons and the Council of that institution has reached another stage. At the general meeting of Members and Fellows held on October 29th, resolutions in favor of reform and of the representation of Members were carried by a large majority. The Council have since (yesterday) held a meeting to consider these resolutions. As only one member was absent the meeting may be regarded as practically representing the whole body. The result of their deliberations may be summed up in two words — *non possumus*. They deliberately refuse what is asked from them. "It is not," they say, "desirable to diminish the privileges of the Fellowship of the College by depriving Fellows of the exclusive rights of electing to the Council," and they consider that it is "quite impracticable" to act upon the second resolution passed at the meeting of Fellows and Members, which was to the effect that no alteration in the constitution, by-laws, etc., of the College should be effected without the consent of the Fellows and Members convened to discuss the same. On these two points, be it observed, the Council were yesterday unanimous. It speaks badly for the good faith of those who were elected to the Council pledged to support the cause of reform, that they should now be as active in opposing it as those who were known as firm supporters of the *status quo*. Were the term of office of Members of the Council limited to three instead of eight years, probably some of these gentlemen would not proceed to eat their own words with such unblushing eagerness. There is, however, no probability of the matter being allowed to rest now. The Fellows and Members are not likely to accept the decision of the Council. Their case, too, is much stronger than it was, inasmuch as many of the Fellows are now disposed to make common cause with the Members. At the adjourned meeting of Fellows and Members, which is to take place next week, a further development of the controversy will probably take place.

At the last meeting of the Royal Medical and Chirurgical Society, Dr. Stevenson Thomson read an interesting paper on "Scarlatinal Albuminuria and the Pre-albuminuric Stage." Dr. Thomson had observed one hundred and eighty cases during a year, and tested 35,000 specimens of urine. As the result of his investigations, he accepts the view that nephritis is almost as essential a feature of scarlatina as the eruption or the sore throat. As regards the pre-albuminuric stage, his opinions differ somewhat from those which have hitherto prevailed, and which have been based chiefly on the investigations of the late Dr. Mahomed. Dr. Thomson has demonstrated the presence of albumen in this stage. In the subsequent discussion, one of the speakers objected to picric acid as a test, and also to potassio-mercuric iodide, both of which, he thought, might be misleading in their delicacy. Dr. Thomson, however, explained that he based his views mainly on the results given with heat and nitric acid in concentrated specimens of urine, and did not rely solely on the picric acid test. He had found both albumen and hæmoglobin in the pre-albuminuric stage, and had also found both of them in the post-albuminuric stage. He had also demonstrated the presence (in both stages) of blood-corpuscles and of casts. He considered the guiacum test a more delicate test for blood than the spectroscope, an expression of opinion in which Dr. Dickinson concurred.

Mr. Owen Fowler remarked that he had seen nearly 2,000 cases of scarlet fever at the London Fever Hospital. Dr. Dickinson considered cold to be an occasional cause of albuminuria, but at the London Fever Hospital they had more albuminuria in summer than in winter. He had found much albuminuria due to high temperature in the disease.

The new "Conjoint Scheme" has scarcely got into working order before there is a cry that it is impracticable. At the October examination it is reported that four-fifths of the candidates were rejected, and loud has been the outcry among the teachers in consequence. The new scheme will probably lead to what will virtually be a lengthening of the curriculum, viz., students will be required to pass the examination in science before commencing their medical course of four years.

The course taken by the two colleges, with reference to the "degree" question, points to the near establishment of a new university in London in close connection with the teachers in the various London colleges. The medical colleges will probably form its nucleus, and will probably give their active support to the promoters of the new Teaching University. The present London University has, in convocation assembled, deliberately refused to meddle with teaching, but to continue to be simply a State Examining Board.

I have to record the death (through an accident) of Dr. W. B. Carpenter, well known as a physiologist, both as a writer and investigator. He was perhaps equally

well known to a wider circle as the indefatigable Registrar, for twenty-two years, of the University of London. Dr. Carpenter took a deep interest in the working of the University, and any word he heard said against it he resented almost as if it were a personal offence. He was strongly opposed to the admission of women to degrees, and resigned his appointment as Registrar in the same year (1878) in which the new charter was granted to admit them. He subsequently, however, consented to serve on the Senate.

OUR PARIS LETTER.

(From our Special Correspondent.)

CONCERNING M. PASTEUR'S INOCULATIONS FOR HYDROPHOBIA—THE EFFECTS OF COLCHICIN—DEATH OF BAILLIÈRE, THE MEDICAL BOOK PUBLISHER.

PARIS, November 13, 1885.

THE debates on cholera have been quite eclipsed, and the so-called Ferranization has been thrown in the shade and greatly distanced, by M. Pasteur's inoculations for hydrophobia. You will have seen and heard, from the medical and lay press, of the discussions that have been going on on the latter subject, so that it will not be necessary for me to repeat them here. I may, however, observe that, notwithstanding the great enthusiasm that has been caused by this would-be discovery, I do not think that M. Pasteur's reputation will be thereby greatly enhanced. The intrepid experimenter seems to have had it much his own way both at the Academy of Sciences and at the Academy of Medicine, though at the latter M. Jules Guérin, the veteran member, questioned the significance of M. Pasteur's experiments and suggested that the pretended cures effected by M. Pasteur's method were no cure at all, as indeed there was nothing to cure, inasmuch as neither the animal that bit nor the subject that was bitten has ever proved to be rabid. At the last meeting of the Sanitary Congress, and in the Section of the Veterinary Surgeons of France, of which M. Pasteur was elected honorary president, the theories of the learned biologist were not received with much favor. The debate on hydrophobia was opened by M. Pasteur, but it cannot be said that much light was thrown on the subject. To begin with, the diagnosis of this terrible affection seems to have been rendered more obscure than ever, for no member present, not even excepting M. Pasteur, was able to furnish positive signs or symptons of the disease, whether in the living or dead subject, and M. Pasteur's response to a question on this point is worth noting. He stated that till now rabies could not be diagnosed with any scientific certainty in the dead or living animal, and that the fact alone of the presence of substances in the stomach of a dog other than those he had taken for his food, will not authorize one to conclude that he was mad. One single experiment would be decisive, and that is inoculation! This is certainly a sorry admission to make, and yet in the face of this uncertainty M. Pasteur goes on inoculating all subjects brought to him and reputed to have been bitten by a mad dog.

The inoculation consists in taking a fragment of the medulla oblongata or of the cerebral substance of an animal suspected to be rabid, and injecting this hypodermatically into another animal. If in the space of a few days the inoculated animal dies, this would be evident proof that the animal which furnished the product of inoculation was mad. It is not, added M. Pasteur, in the saliva, as is generally believed, that the rabid virus in its purity must be sought for, the saliva contains too many impurities for this. Moreover, it has been experimentally shown that rabies is developed not in the blood or lymph, but it is exclusively in the nervous system that the rabic virus is localized and concentrated; therefore the animal should not be killed prematurely, but allowed to die naturally, in order to make sure that the rabic virus had time to reach the spinal marrow and medulla oblongata, and there to localize itself. M. Pasteur concluded his discourse with the remark that it was not only because foreign substances were found in the stomach of the dog that bit the boy Meister—M. Pasteur's first human subject, and who it will be remembered was inoculated by him in July last—that the latter inferred the existence of rabies, but it was because the medulla oblongata of this dog, inoculated into other animals, transmitted the disease. In the present stage of our knowledge of this supposed cure for hydrophobia, I think it would be premature to practise these inoculations, particularly as it is known that, of a hundred persons bitten by dogs known to be really rabid, ninety have escaped the disease. Moreover, the stage of incubation is so variable, extending as it does from about a fortnight to several months and even years, it would be often difficult, if not impossible, to trace the connection between the time of infection and the outbreak of the symptoms. Under these circumstances it would be advisable not to trust to these anti-rabic inoculations, but to resort without delay to the time-honored remedy, the actual cautery, as again recently advocated by the Council of Hygiene of Paris.

The law of July, 1881, prescribes that all dogs even suspected of being mad shall be destroyed. One of the members present protested against this law as being too arbitrary, and went so far as to say that, if carried out, it might be compared to the massacre of the innocents (?) M. Nocard, a veterinarian of some note, as if to give some satisfaction to the scruples of the speaker, proposed to make over all edible animals—such as oxen, cows, sheep, &c.—that might have been bitten by a rabid dog to the butcher for sale, declaring that there is no danger whatever in handling or consuming meat contaminated by rabic virus. This proposition raised a storm among the audience by way of protesting against it, when one of the members, as soon as silence was restored, put the question as to who would dare to affirm that meat contaminated by rabies could be consumed without danger. At this question another member stepped forward and declared that such meat was absolutely inoffensive, and added that he spoke from personal experience, having eaten not only once but a hundred times, cooked or raw, of the flesh of rabid cows and farcinous horses. This caused a murmur of horror among the audience, and one of the members exclaimed that fortunately the public are protected by an article of law which formally interdicted the sale for consumption of the flesh of animals killed on account of some contamination or other.

The recent trial of a florist, accused on suspicion of having poisoned his wife with colchicin, but who was acquitted, as no positive proof could be brought against him, has induced experimenters to discover some means by which the presence of this alkaloid may be detected in the system. M. Laborde lately presented a note at the Société de Biologie on the physiological effects of colchicin that he observed in guinea-pigs, dogs, and rabbits. It is said that a dose of one centigramme determined a commencement of poisoning, characterized by nausea and vomiting. And yet it has been recorded that a patient had taken by mistake forty centigrammes of this alkaloid without having been poisoned, and without having felt any other inconvenience than a little diarrhœa, syncope, and headache. Another patient took as much as one gramme in a single dose, and only presented analogous symptoms. It is, however, worthy of remark that a gouty patient is relieved in his arthritic joints at about the fifth or sixth granule of one milligramme each, after slight vomiting and a little diarrhœa. There is a well-known patent medicine called "La Liqueur de Colchique de Laville," which is a popular remedy in this country for gout, and by the administration of which the same physiological and therapeutic effects have been noticed.

M. J. B. Baillière, the well-known medical bookseller in Paris, died on the 8th ult., in the eighty-ninth year of his age. From his age he was called the "doyen" of the medical booksellers of this country. He was a great favorite among the members of the profession, and although he became blind in the latter years of his life, he never quitted his business.

REPLY TO DR. DUGGAN.

To the Editor of The Medical Record.

Sir: Out of consideration for your readers and for my time I shall reply as briefly as possible to Dr. Duggan's remarkable communication, published in The Medical Record of September 12th. The facts are as stated in my letter of August 1st, and I leave the profession to judge of the value of Dr. Duggan's criticisms, and of the propriety of his publishing them under the circumstances mentioned.

Dr. Duggan says that he gave up work for the Committee on Disinfectants in January. It is true that at the end of January I informed him that the funds at my disposal would not permit me to continue to pay him for his services; but it is also true that he promised to make some additional experiments without compensation, and that I was in daily expectation that he would resume his experimental work for the committee up to the time that I decided to place the further testing of commercial disinfectants in the hands of Dr. Abbott.

In attempting to justify his action, Dr. Duggan says: "Perhaps my principal reason for not communicating directly with Dr. Sternberg was that I felt convinced that any criticism made in this way would not reach the profession. I know that this statement requires explanation, which I can only give by citing a past experience."

When the facts relating to this "past experience" are fairly considered, it will be seen that this attempt to impeach my scientific accuracy and honesty is simply ridiculous.

The criticism made by Dr. Bartholow, to which Dr. Duggan refers, arose from a misapprehension which was fully explained in my paper on potassium permanganate, published in the *Medical News* of January 10, 1885. This will be made apparent by the following quotation from this paper:

"Continuing to quote from Bartholow, we find the following:

"'We must acknowledge a certain sense of scepticism in examining these experiments of Dr. Sternberg, as able and well-considered as they unquestionably are. We find it difficult to understand why liquor zinci chloridi has no germicide action, whilst a two per cent. solution of the same is effective in the proportion of one part to fifty.'

"Dr. Bartholow's scepticism is well founded from his point of view, but it results from a misapprehension. I do not say that liquor zinci chloridi has no germicide action, but I record its failure to destroy the micrococcus used as a test-organism in the following experiments: Commencing at one per cent.—the time of exposure being, as in all of these experiments, two hours—and meeting with a failure, the following experiments were made, two per cent., four per cent., eight per cent. Meeting with a failure in every case, I proceeded to test the pure salt—zinc chloride. This failed in the proportion of 0.5 per cent. and of one per cent., but was successful in the proportion of two per cent. (Experiment in duplicate, see Table No. I.). In my Table No. II. this result is stated as follows:

"'Zinc chloride (two per cent.) one part in fifty.'

"The misapprehension has arisen from the fact that Professor Bartholow has taken this to mean that one part in fifty of a two per cent. solution is efficient, whereas it means that one part in fifty of the pure salt is efficient, and the two per cent. in parenthesis is simply introduced from the previous table as the equivalent of one part in fifty.

"According to the National Dispensatory, the liquor zinci chloridi should contain about fifty per cent. of the pure salt. If the specimen tested was of this strength, it should have been efficient in the proportion of four per cent., or 1:25; but it failed in two experiments in this proportion, and in one in the proportion of eight per cent. The biological test is sufficiently accurate to make it appear probable that this particular specimen did not come up to the standard."

My inference that *this particular specimen* was below the standard of strength is fully justified by a comparative test made at the same time, by the same method, and upon the same organism—a micrococcus—with a solution made from the pure salt. Dr. Duggan testing a different sample of the solution two years later, and upon different test organisms—the bacteria of putrefaction in broken-down beef-tea—and finding by chemical analysis that this sample contained fifty per cent. of zinc chloride, assumes that the sample tested by me in 1883 also contained the same amount, and has the presumption to say that having informed me of the fact he has "waited in vain" for me to "publicly correct" my error. This, as already stated, is simply ridiculous. I know nothing of the history of the sample tested by me which I found upon the shelves of the Post Hospital Dispensary at Fort Mason, Cal., and in recording my results in a table in my paper referred to, I had no intention of reflecting upon the fair fame of Dr. Squibb, whose label was upon the bottle. I simply recorded the results which I had obtained. In the same way I have recorded Dr. Duggan's results, in testing another sample, in the paper on commercial disinfectants. I do not doubt that Dr. Duggan's sample contained fifty per cent of zinc chloride, for he determined this by chemical analysis. I do not doubt that the sample examined by me contained less than fifty per cent. of zinc chloride, because in carefully conducted experiments I found that it failed to kill micrococci in eight per cent. solution, while the same organism was destroyed by a two per cent. solution of the pure salt.

Dr. Duggan's second specification is as preposterous as the first. In my letter of August 1st I make the statement that Dr. Duggan's experiments were made at the expense of the Committee on Disinfectants and by my method. This simple mention of my method leads Dr. Duggan to say that "Dr. Sternberg speaks of his method as though he had a proprietary right in it," and to suggest that I should "take out a patent." As a matter of fact I have frequently demonstrated my method of testing disinfectants to visitors to the laboratory in Dr Duggan's presence, and have published a full account of it in my paper already referred to (*American Journal of the Medical Sciences*, April, 1883).

Dr. Duggan further says: "If better proof is needed to show that he considers his method of the cultivation of bacteria private property, it lies in the fact that during this work he required a 'trusted assistant' to promise that if his services were asked for by a certain distinguished investigator he would not give them, as that gentleman was anxious to secure some one acquainted with his methods of work, and thus do work for which he (Dr. Sternberg) ought to have the credit."

This statement is based upon what Dr. Duggan overheard of a confidential conversation in the laboratory, in which I asked Dr. Abbott to promise not to leave me in less than a year, in case he had an offer which was more advantageous in a pecuniary point of view. This request was in no way based, as suggested by Duggan, upon a desire to prevent others from using my methods, but was founded simply upon my desire to retain the services of a gentleman who had proved himself especially apt at mastering technical details. As Dr. Abbott was receiving compensation for his services while still a beginner in bacteriological work, I thought it not unreasonable

to ask that he should give me, for a certain time, at the same compensation, the benefit of the technical skill he was acquiring in work carried on under my direction, and that he should agree not to leave me on short notice in case he was offered a more remunerative position in another laboratory.

This reasonable desire to retain the services of a skilled assistant induced me to ask Dr. Abbott to give me the promise referred to by Dr. Duggan, who happened to be in the laboratory at the time of my confidential conversation with Dr. Abbott.

Dr. Duggan's statement that one of the members of the Committee on Disinfectants intimated to him that a contribution to the funds of the committee by the firm of manufacturing chemists, in whose employ he was, would be acceptable, I believe to be without foundation. Certainly I never made such a suggestion to him or to any one else.

Dr. Duggan persists in misinterpreting the plain directions given in regard to the disinfection of privy vaults and says: "Any one having read the report of the committee will see that there is no intimation that mercuric chloride should be dissolved before it is placed in vaults; and, in fact, this looks very much like an after-thought on the part of the chairman of the committee." The members of the committee can all testify that this is not true, as any one who can understand plain English may see for himself in the following quotation from the preliminary report: "Disinfection may be accomplished either with corrosive sublimate, or with chloride of lime. The amount used must be proportioned to the amount of material to be disinfected.

"Use one pound of corrosive sublimate for every five hundred pounds—estimated—of fecal matter contained in the vault, or one pound of chloride of lime in every thirty pounds.

"Standard Solution No. 4, diluted with three parts of water, may be used. It should be applied—the diluted solution—in the proportion of one gallon to every four gallons—estimated—of the contents of the vault.

"If chloride of lime is to be used, one gallon of Standard Solution No. 1 will be required for every gallon—estimated—of the material to be disinfected.

"All exposed portions of the vault, and the woodwork above it, should be thoroughly washed down with the disinfecting solution."

As the final report of the Committee on Disinfectants is now ready for presentation at the next meeting of the American Public Health Association (in December), I must decline to give any more time to the discussion of the recommendations made in the preliminary report, which was made by special request of the Sanitary Council of the Mississippi Valley, in anticipation of a possible epidemic of cholera.

GEORGE M. STERNBERG,
Major and Surgeon, U.S.A.

BERLIN, October 27, 1885.

TINCTURE OF COBWEB.—Dr. W. G. Macdonald, of this city, sends us the following formula for the preparation of tincture of cobweb, as desired by a correspondent. "A bunch of spider-web collected from a dark cellar, about the size of a large walnut, is put in about four ounces of whiskey and allowed to macerate forty-eight hours, and then filtered. A teaspoonful is taken about four hours before the expected chill, and at hourly intervals, until four doses are taken, and then a dose before each meal and at bedtime, until all is taken." The web of a species of spider which inhabits dark places is supposed to possess the best medicinal properties.

A NEW PROTECTION FOR VACCINATION SCABS.—Bunion shields are said to be in great demand for the protection of vaccination scabs. Happily this novel use of the shield is calculated to afford relief to the dealer's pocket as well as the purchaser's arm.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 15, 1885, *to November* 28, 1885.

HEGER, ANTHONY, Major and Surgeon. Member of the Army Medical Examining Board now in session in New York City, is relieved from the additional duty of Attending Surgeon in that city, to take effect when Lieutenant-Colonel Joseph R. Smith, Surgeon, shall have arrived in New York and entered upon that duty. S. O. 267, A. G. O., November 19, 1885.

ELBERRY, F. W., Captain and Assistant Surgeon. Sick leave of absence further extended six months on surgeon's certificate of disability. S. O. 263, A. G. O., November 14, 1885.

STRONG, NORTON, Captain and Assistant Surgeon. Relieved from duty at Fort Union, N. M., and ordered for duty as Attending Surgeon, Headquarters District of New Mexico, and Post Surgeon, Fort Marcy, N. M. S. O. 171, Department of Missouri, November 16, 1885.

EWING, C. B., First Lieutenant and Assistant Surgeon. Now at Fort Leavenworth, Kan., ordered to proceed to Fort Reno, Ind. T., and report to Commanding Officer for temporary duty in the field. S. O. 170, Department of Missouri, November 13, 1885.

WINNE, C. K., Captain and Assistant Surgeon. Assigned to duty as Post Surgeon, Benicia Barracks, and Attending Surgeon at Benicia Arsenal, Cal. S. O. 109, Department of California, November 20, 1885.

REED, WALTER, Captain and Assistant Surgeon. Granted leave of absence for one month, with permission to apply for one month extension, to take effect about December 1, 1885. S. O. 114, Department of the Platte, November 18, 1885.

TAYLOR, ARTHUR W., Captain and Assistant Surgeon. Granted leave of absence for one month, to take effect December 5, 1885. S. O. 116, Department of the Platte, November 20, 1885.

CHAPIN, A. R., First Lieutenant and Assistant Surgeon. Ordered for temporary duty at Fort Robinson, Neb. S. O. 115, Department of the Platte, November 18, 1885.

SIMONS, JAMES, Lieutenant-Colonel, U. S. A., retired, died November 11, 1885, at Baltimore, Md.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 28, 1885.

DRENNAN, M. C., Surgeon. Ordered to Training Ship New Hampshire.

NICK, H. A., Surgeon. Detached from Training Ship New Hampshire and wait orders.

FITTS, H. H., Assistant Surgeon. Ordered to appear before Examining Board preliminary to promotion.

RUSH, C. W., Passed Assistant Surgeon. Granted sick leave for three months from November 20, 1885.

MARMION, R. A., Surgeon. Detached from Marine Barracks, Washington, D. C., December 7th, and wait orders.

MOORE, A. M., Surgeon. Ordered to Marine Barracks, Washington, D. C., December 7, 1885.

THE FIRST CONGRESS OF SWEDISH PHYSICIANS was held in Jönköping on September 3, 4, and 5, 1885. Among the subjects discussed were the best means of preventing the introduction of epidemics into cities and rural districts, and the treatment of diphtheria by cyanide of mercury. Among the papers read were one by Dr. Westermark on Salpingitis, by Dr. Ivar Svensson on the Radical Operation for Hernia, by Dr. Warfuinge on Antipyresis, and by Dr. Sven Bayer on Bacteriological Studies in Relation to Cholera.

The Medical Record

A Weekly Journal of Medicine and Surgery

Vol. 28, No. 24 NEW YORK, DECEMBER 12, 1885 Whole No. 788

Original Articles.

A SUCCESSFUL CASE OF NEPHRECTOMY FOR CALCULOUS PYELITIS.[1]

BY FRANCIS J. SHEPHERD, M.D.,

PROFESSOR OF ANATOMY IN M'GILL UNIVERSITY, SURGEON TO THE MONTREAL GENERAL HOSPITAL.

EXTIRPATION of the kidney, though now an operation of comparative frequency, is of such recent origin that surgeons are not yet agreed, either as to the cases in which it is justifiable or as to the proper method of its performance. Most of the advocates of the abdominal operation are specialists in abdominal surgery, while the verdict of the general surgeons is largely in favor of the lumbar operation. As, in the large majority of cases, the surgeon is unable to say till the kidney is reached, whether nephrotomy or nephrectomy should be performed, and even abdominal surgeons admit that the lumbar incision is the most suitable for nephrotomy, it seems to me that this reason alone should strongly influence us as to the choice of operation. The lumbar operation is, without doubt, the safest operation in the hands of surgeons who are not specialists in abdominal surgery, notwithstanding all that is now said about the "traditional fear" of opening the peritoneal cavity, being a ghost of the dark ages of surgery which has been effectually slain.

Extirpation of the kidney for calculous pyelitis has been a particularly fatal operation, especially when undertaken in advanced cases of the disease. The mortality has been so great that it has been advised by many that a preliminary nephrotomy should, in all cases, be performed; others, again, strongly recommend drainage of the kidney alone, in cases where the organ is in an advanced stage of suppuration, and when it is surrounded by such an amount of cicatricial tissue as would render its removal a hazardous procedure.

The following case of nephrectomy for advanced calculous disease is, I trust, not without interest, and adds one more case to the list from which the rules governing renal surgery will, in the future, be formulated.

I am indebted to Dr. Gustin, my house-surgeon, for the history of the case.

Eliza T——, aged twenty-four, married, was admitted into the General Hospital under Dr. Wilkins, on August 10, 1885, suffering from a painful swelling in the left side of the abdomen. Family history throws no light on the case; no consumption. Has had two children and one miscarriage. She recovered rapidly from her first confinement, but convalescence was tedious after the second. Up to two years ago was always a very healthy woman. She dates the commencement of her illness from nine months ago, when she began to lose flesh and to suffer pain in the left lumbar region, pain occasionally reached as far as the thigh. She attributed these pains to the pressure of the pregnant uterus. She first noticed a "lump" in the left side of her abdomen two years ago, after the birth of the first child; it was movable, tender on pressure, but not painful. It gradually increased in size, and became painful. Five months ago she noticed that her urine was milky, and that if it stood for a short time a considerable deposit appeared. Occasionally the urine would be quite clear for two or three days, and then there would be a large amount of deposit. She never had anything resembling blood in the urine, nor had she ever had any attack at all like renal colic; never had had any chills or sweatings.

On admission into hospital, the following note was made concerning her condition: "Patient extremely emaciated and anæmic, with an anxious expression of countenance; skin dry, of a sallow hue, and hangs loosely over the tissues; tongue red and flabby; bowels regular; no cough; lungs on examination are found perfectly healthy. Patient is very weak; has a pulse of 14c, and temperature, 101° F.

"Has painful and frequent micturition, and complains of pain in the lumbar region which shoots occasionally down as far as the thigh.

"*Abdomen.*—On examining the abdomen, the superficial veins are seen to be much enlarged on both sides, as if there were some deep-seated obstruction. A distinct fulness is seen in left lumbar and iliac regions. Palpation reveals a large tumor extending across to within an inch of the umbilicus, continuous with the splenic dulness above, and below reaching as far as the brim of the true pelvis. By bimanual palpation the tumor can be grasped between the hands and moved slightly. No fluctuation made out, but tumor feels very elastic, and on pressure it is very tender. Urine has a specific gravity of 1.020, is slightly acid, and after standing a few minutes deposits a large amount of pus. On microscopic examination no casts are found, but pus-globules and oxalate and phosphate crystals are seen in abundance."

In the last week of August, Dr. Wilkins transferred the patient to the surgical wards, where she came under my care. At that time her condition was somewhat improved, she had gained flesh, but was still greatly emaciated. Her pulse, however, was still rapid (140), and her temperature ranged from 99° to 101.5°. The tumor had not increased in size since her entrance.

The diagnosis of the case rested between tuberculous and calculous pyelitis. The history of the case pointed, however, rather to the latter affection, on account of the pain, occasional absence of pus in urine, and the absence of any phthisical history; on the other hand, there had never been any blood in the urine.

The condition of the patient not improving, the pulse remaining at 140, and the temperature sometimes running up as high as 103° at night, after consultation with my colleagues I decided to explore the left kidney through a lumbar incision, and to perform nephrotomy or nephrectomy, as would be determined by the condition of affairs found on reaching the kidney.

Operation.—On September 17, 1885, the patient having been etherized, the right kidney was first examined by palpation, and easily made out to be normal in size and apparently healthy. It was freely movable. The woman was now placed on her right side, in the colotomy position, with a pillow under her right loin. An incision was made, a little nearer the rib than the iliac crest, from the edge of the erector spinal muscle, downward and forward for nearly six inches. There was plenty of room between the last rib and crest of the ilium, the distance being somewhat greater than usual.

After dividing the various structures, the quadratus lumborum muscle was reached, and its most external fibres were divided transversely, so as to give more

[1] Read before the Montreal Medico-Chirurgical Society, October 23, 1885.

posteriorly. During the dissection there was pretty free venous hemorrhage, owing to the distended state of the veins.

The kidney tumor now came into view; it was distinctly fluctuating, and on aspirating it, stinking pus was drawn off; passing the hand around the kidney in the direction of the pelvis, a hard substance was felt, which by needle exploration was found to be a calculus. An incision was now made into the most prominent part of the tumor, and nearly a pint of very fetid pus evacuated. Through this incision the kidney was explored with the finger, and a large calculus was felt filling up the pelvis and calyces of the kidney and extending down into the ureter. The kidney was converted into a large sacculated pus-containing bag as large as a fœtal head, with numerous outlying cysts with thin walls. Seeing the extent of the disease and the impossibility of removing the calculus, I forthwith decided to remove the kidney. The incision already made was found too small to satisfactorily free the kidney from the surrounding structures, so it was enlarged by incisions at right angles to the original one, about its middle. In this way plenty of room was obtained, and the whole hand could be introduced for the purpose of freeing the kidney.

The upper end was freed without difficulty from the capsule and suprarenal body, which was left behind. The lower and posterior part was not so easily separated, as there were many adhesions—in fact almost a cicatricial condition of the surrounding structures. To give still more room many of the projecting cysts were punctured and the contained pus let out; in one of these cysts a stone, the size and shape of a marble, was found.

The posterior surface of the lower end of the tumor, which extended deep down in the iliac fossa, was the most troublesome part to clear, and some hemorrhage from the engorged veins occurred during the process. The peritoneum, however, escaped uninjured. The vessels entering the hilus were now tied with a strong carbolized silk ligature, which was cut short. The vessels were then divided, and the kidney delivered through the wound with ease. The ureter was also tied, cut, and brought out as near as possible to the edge of the wound. It was of normal size, except near the kidney, and was apparently healthy. After dividing a few bands of cellular tissue about the hilus, the kidney was removed.

During the freeing of the kidney there was considerable venous hemorrhage, and much oozing continued after the removal of the organ; several bleeding points were secured and tied with catgut, and the oozing arrested by sponge-pressure. The cavity left by the removal of the tumor was almost immediately filled up by the intestines, which pushed forward the peritoneum. The wound was now irrigated with bichloride 1 to 2,000, and then brought together with catgut sutures, dusted with iodoform, covered with a pad of sublimate jute, and over all a broad gauze bandage. A large drainage-tube, I omitted to mention, was inserted into the lower end of the wound.

The patient, although suffering considerably from shock, rallied well. She had a little vomiting, which was controlled by champagne, and, for the first four-and-twenty hours, she was fed per rectum by brandy and beef-tea enemata.

During the night after the operation there was considerable oozing, and the dressings had to be changed on the second day; at this dressing the drainage-tube was much shortened. About thirty ounces of urine was passed in the twenty-four hours following the operation; it contained some blood and a small amount of pus; after the third day neither blood nor pus were found in the urine. Her pulse, which before the operation was 140, soon fell to 115, and the temperature after the first day never reached 100° F. The patient made an uninterrupted recovery, the wound healing by first intention everywhere except at the point of drainage. In two weeks she was sitting up, and in three wheeling herself about the ward in a chair. Her appetite was now enormous, and she rapidly gained flesh. By October 17th she was walking about, and looking quite healthy and strong. The daily amount of urine passed was from forty-five to fifty ounces, of a specific gravity of 1.020.

The calculus on examination proved to be composed chiefly of oxalates.

There are several points of interest in this case:

First.—The ease with which, in the patient's emaciated condition, the right kidney could be felt and recognized to be of normal size.

Second.—The large amount of room obtained by the crucial method of incision.

Third.—The satisfactory way in which, notwithstanding the advanced state of the disease and the number of adhesions, the kidney was removed without wounding the peritoneum or other important structure.

Fourth.—The rapidity with which the large cavity, caused by the removal of the tumor, was obliterated by the intestines pushing forward the peritoneum.

I feel certain that, in this case at least, the lumbar operation was the more suitable; had an attempt been made to remove the organ by abdominal section, it would have been impossible to avoid breaking the thin-walled cysts, and so allowing some of the fetid pus to get into the peritoneal cavity.

P. S., November 23d.—When last seen, a day or two ago, the patient was attending to her household duties, and feeling strong and well. There was still a sinus, large enough to admit a small probe, where the drainage-tube had been. There was very little discharge from the sinus.

MONTREAL, November 24, 1885.

OPERATION FOR CONGENITAL EXTROVERSION OF THE BLADDER OF AN INFANT FIVE DAYS OLD.

BY HAL C. WYMAN, M.D.,

SURGEON WEST END DISPENSARY, DETROIT, MICH.

IN November, 1884, I was summoned to see an infant, born of German parents, in this city. The child was four days old, and appeared in every respect healthy excepting a malformation of the genito-urinary tract. From the umbilicus down to the triangular ligament there was a want of development which caused an extroversion of the posterior wall of the bladder, showing the orifices of the ureters, also an absence of the dorsal portion of the penis from the crus to the glans. Through this large opening the posterior wall and base of the bladder with the prostate gland protruded, making a most unsightly deformity. The urine constantly dribbled away from the ureters, soiling the limbs and body of the child. The parents were unusually intelligent, and appreciated fully the nature of the deformity, and begged of me to make some effort to improve it. I decided to operate, and on the day following, the child being five days old, with the assistance of Drs. Chuney and Clark, of this city, the child was given chloroform and the mucous membrane removed in a strip one-half inch wide, running around the margin of the vesical wall, where it blended with the integument of the abdomen, excepting a small area which corresponded to the inferior wall of the urethra. Then an incision was made in each side through the integument and superficial fascia arising from Poupart's ligament, just forward of the anterior superior spine of the ilium, upward, a distance of two inches, for the purpose of securing sufficient relaxation of tissue to let the opposite pared surfaces come together and unite. The pared surfaces were then transfixed with three hare-lip pins, and a figure-of-eight ligature was passed about them, bringing the margins of the abdominal cleft in contact; additional sutures were passed between the pins

and on either side of them, securing perfect apposition of opposing surfaces. The line of union was now dusted with oxide of zinc and covered with absorbent cotton. The perpendicular incisions stretched out under the tension due to closure of the abdominal cleft, making wounds an inch in width. They were dressed with lint and cosmoline, no effort being made to close them. A small drainage-tube was left in the bladder and served to constantly drain away the urine, so that it did not come in contact with the wound. No effort was made to restore the dorsal portion of the penis or urethra, owing to the severe hemorrhage which resulted from the denudation of such a large amount of tissue as was involved in the bladder. Then the making of a useful urethra out of the redundant integument of the scrotum and penis would be a comparatively easy matter after the large abdominal cleft had been closed.

The amount of blood lost was all that the appearance of the infant would warrant us in taking. From a healthy red color it had changed during the operation to a death-like white, and this not due to simple blanching of the surface, as shown by feeble pulse, etc. After cessation of the anæsthesia the little patient revived, looked bright, and took the breast vigorously. No anodynes were necessary to control pain, and little distress seemed to follow the operation. On the third day the normal color of the child had returned, showing that out of mother's milk and fresh air sufficient red blood had been manufactured to compensate for the large amount lost during the operation. The child progressed rapidly to recovery and a perfect union of the surfaces apposed by sutures. It was my intention to make a second operation for the restoration of the urethra and dorsal portion of the penis, when, two months later, the child was attacked with convulsions, which terminated fatally, but had no apparent cause in the conditions leading to or growing out of the operation for cure of the extroverted bladder.

There are two points in this case which the writer deems especially worthy of the attention of the profession. One is the early age at which the operation was performed, and the second is the facility with which the child rallied from shock and hemorrhage. The good results which have followed the early performance of hare-lip operations in the writer's hands (in several instances the third day after birth), and the excellent union and relief of deformity in the present case, lead him to advocate early resort to operative measures in all cases of congenital extroversion of the bladder.

THE SEPARATION OF MATERIA MEDICA AND THERAPEUTICS.—Professor Horatio C. Wood, of Philadelphia, writes: "In your issue of November 21st is a letter from Dr. Mary Putnam-Jacobi, in which attention is called to the separation of the materia-medica course from that of therapeutics in the Woman's Medical College of New York, and the assertion made that such separation 'is an entirely original one and entirely peculiar to our school.' The first impulse of gallantry was to leave Mrs. Jacobi and her self-congratulations undisturbed; but justice seems to require the statement that in the University of Pennsylvania such separation was made as long ago as 1878, and has been fully carried out ever since. The first year of the student is occupied in part by a course of laboratory instruction in practical pharmacy and in the study of pure materia medica, and he is required to pass an examination—including the putting up of a prescription—on each of these subjects before entering the second year. During the second and third years the physiological action of drugs and practical therapeutics receive the student's undivided attention.

Dr. J. M. Baldy, of Scranton, Penn., a graduate of the University of Pennsylvania, sends us a communication to the same effect.

A CASE OF PHTHIRIASIS PALPEBRARUM.

REPORTED BY FRANK W. RING, M.D.,

ASSISTANT SURGEON MANHATTAN EYE AND EAR HOSPITAL, NEW YORK.

MASTER J. K——, ten years of age, came to the Manhattan Eye and Ear Hospital, October 10, 1885, and was admitted to Dr. Roosa's clinic. Upon a hasty examination he diagnosed a case of phthiriasis palpebrarum, and kindly turned the patient over to me for a more thorough examination.

Upon the left upper lid I found three rows of cilia, and upon the right two, making a most acceptable place for a prolific reproduction of the parasite. The lids had a dirty, disgusting-looking appearance, and upon close inspection each cilium was found to be the recipient of a nit, so closely adherent that it could not be removed without pulling the lash from the lid.

The lids were thoroughly washed with a solution of soda and water, and then, by stirring up the closely adherent excrement and dirt at the roots of the lashes, two or three insects were removed which were supposedly recognized as pediculi pubis, commonly known as the crab-louse. It was quite difficult to dislodge them, as they were deeply fastened into the tissue of the lid. An application of the ointment of the red oxide of mercury was smeared over the lids, the cilia being cut close, to dispose of the nits.

In two days the patient returned with the lids looking better; but upon close inspection I found evidences of the parasite, and with a little patience removed eight insects with the cilia forceps; then, with a cotton-pointed probe I applied some heated blue ointment thoroughly to the upper and lower lids, sending the boy home with the caution not to wash the eyes for three or four hours.

In three days the patient returned to the hospital, and a thorough examination was made with no apparent signs of any insect remaining; he was dismissed as cured, only to make his appearance a fortnight later, with several nits glued to the stubs of the cilia, and three insects at their roots; they were removed, a fresh application of ointment made, and the lad has not returned, so that we naturally infer he is no longer afflicted.

Dr. W. H. Fox kindly mounted some of the specimens, and I put them under the microscope to make sure of their identity. They were compared with the cuts accompanying an article in "The Royal London Ophthalmic Hospital Reports" (vol. ii., p. 125), by Mr. W. W. Harkness, and found to be of the same variety.

I also found in the same reports (vol. v., p. 239) a case of pediculi palpebrarum in a child three years of age, reported by Dr. Steffen, who had never heard of a like case before. There is no record of phthiriasis palpebrarum in Knapp's *Archives*, "Trans. Amer. Ophthal. Society," or *The Ophthalmic Review*, all of which I searched in their entirety; also portions of *The American Journal of Ophthalmology*, and "Trans. British Ophthal. Society." The records of the Manhattan Eye and Ear Hospital show a ratio of one to fifty-seven thousand.

Dr. David Webster had been looking for a case of pediculi palpebrarum for thirteen years, during which time he has probably treated over fifty thousand patients. Dr. Roosa kindly furnished the patient referred to. I infer from the foregoing facts that such cases are exceedingly rare, which is my apology for reporting this one.

How the child became affected I do not know. The mother said the boy had come from Staten Island, where he had passed the summer; also that he spent considerable time in the hen-house. The lad informed me he slept with two brothers, seventeen and eighteen years of age, which habit I stopped.

I am aware that the hen-louse is not of the pediculi pubis variety; if it was, I should attribute the infection to his familiarity with the hens.

Dr. Kipp, of Newark, had a patient who came from the country every fall with lice in his lashes.

101 PARK AVENUE.

SOME OBSERVATIONS ON THE OPERATION OF TRACHEOTOMY IN CROUP, AND ITS AFTER-TREATMENT.

By SAMUEL KOHN, M.D.,

NEW YORK.

It is significant that, after all that has been said and written in favor of the operation of tracheotomy in the croup of children, there should still be a number of physicians of large experience who deny its beneficence.

It is the aim of the writer to look into some of the causes for this skepticism; to describe some of the dangers which, in his experience, have beset the unfortunate little patient after the operation has been performed, and the steps he has taken to avoid or palliate them.

It is not to my purpose to quote statistics, to discuss the merits of canulas, or to cite the literature of the subject. Exhaustive articles on tracheotomy in croup are to be found in the files of the medical journals of every language for the last decade, and in text-books.

The mention of the names of König, Krönlein, Kuster, Meigs and Pepper, Jacobi, and Ripley, calls to mind only a few of the excellent contributions to our knowledge of the subject.

Having performed the operation in ten cases, I desire to present the result of my observations, and possibly to gain a convert or two from the ranks of the non-believers.

Much has been said of the "early" and "late" operations in croup, and many a patient has died asphyxiated, because his physician, under the influence perhaps of the last article on the subject he has read, advocating only "early" operation, thought the disease too far advanced for any operative procedure to be of benefit. To such prevaricators Krönlein and Jacobi say, in effect, "it is never too late to operate, no matter how deep the carbonic acid intoxication, how severe the disease, or how young the child; that humanity compels the physician to perform that operation which will cause oxygen to reach the lungs; that, in short, when it becomes evident that the *principal danger* from which the child is suffering is *laryngeal obstruction*, no consideration whatever should prevent the performance of the operation."

The writer has among his cases two in which tracheotomy was deferred until the cyanosis had reached apparently the highest possible degree, and both of these patients recovered.

The first of these, a boy, two years and three months old, when seen for the first time, August 30, 1883, at eight o'clock in the evening, with Dr. Althaus, of this city, presented all the symptoms of membranous croup: a temperature of 103° F., retraction of the soft parts of the chest on inspiration, hoarse and at times aphonic cough, noisy laryngeal respiration. Immediate tracheotomy was advised, but the mother of the child, who was here on a visit from Cincinnati, begged that it might be postponed until she could communicate with her family. It was told her that we might wait and try the ordinary remedies. In spite of all our efforts, the cyanosis grew deeper, until on the early morning of September 1st the operation was performed, with the kind assistance of Drs. Bell and Althaus. We told the mother that the chance of saving the child's life was minimal, that there was mild diphtheritic intoxication present, but she asked us to do anything that would give air to the child, and relieve its terrible sufferings. Although this patient was in a state of complete muscular relaxation and deep cyanosis, he was restored to health by the operation.

The second case, very similar to the one just described, was in a girl of about four years, who was *in extremis* when the operation was performed. It was a case of diphtheritic croup in the practice of Dr. Ludwig Weiss, of this city, the late Dr. C. Krog, of this city, and myself being in consultation. The patient was as limp from muscular relaxation as though inanimate; inspiration and expiration both very short from almost complete glottic occlusion; the operation was beset with such difficulties that each of the three physicians successively attempted to find the trachea, it finally falling to my lot to reach it. Notwithstanding her precarious condition at the time of operating, this patient also recovered. These cases are instanced to show that "lateness" of operation or the presence of complications does not of necessity make a fatal result inevitable. Many cases of the same kind are to be found in the literature. On the other hand, recoveries have been reported in apparently serious cases without tracheotomy; such cases only prove that the operation should not be performed until, after carefully watching the progress of the case, it becomes evident that no other resource is left.

To the "too early," or, to use slang, "too previous," operator these reported cases of recovery without operation must be a terrible reproach when his operation terminates fatally. If the croup membrane be so disposed in the larynx that, although both vocal cords be covered and the glottis narrowed, the rima still admits sufficient air to sustain life, the child can recover; and to expose it to the additional dangers of tracheotomy unnecessarily is, in my opinion, unjustifiable. A little judgment is, of course, necessary to distinguish between these cases. It has been my rule not to operate until, notwithstanding the application of appropriate remedies, the barking cough, the sawing inspiration, the hoarseness, gave place to aphonic cough, to marked interference with both respiratory acts, and to aphonia, the general symptoms becoming correspondingly marked. The physician who views tracheotomy in croup with disfavor finds himself, when confronted by a case of this disease, on the horns of a dilemma—shall he perform an early operation, to be followed possibly by the death of the patient, attributable to the tracheotomy perhaps, or shall he inflict additional suffering on the already over-tortured patient by operating "late," with the certainty, according to some writers, of a fatal result? If he will remember that at no time, until death occurs, is it actually too late to tracheotomize, he will be enabled to easily come to a decision, and to carry it into effect without trepidation.

In regard to after-treatment, the *trained nurse* is an *all-important* factor; the constant watchfulness of the nurse who thoroughly understands the methods of combatting the ever-recurring emergencies in these cases will serve to relieve the physician of much anxiety, and will materially contribute to the patient's recovery. In all of my cases have I insisted on the *absolute necessity* of having a competent nurse, preferably a male, in charge of the after-treatment, and, where the family could not afford it, I have defrayed the expense, rather than run the risk of losing my patient through the over-zealous but faulty nursing of the parents and relatives.

The trachea having been opened, and the canula introduced, a mass of mucus, blood, and occasionally shreds of membrane, are expelled by a tumultuous aphonic cough, absence of which at this time is considered a bad prognostic sign, as indicating the abolition of sensibility in the tracheal mucous membrane. The introduction of a soft gum catheter through the canula into the trachea usually was successful in bringing about a spell of coughing, with expulsion of the tracheal contents.

The desiccation of the tracheal and bronchial secretions in the canula, and around its internal opening, the danger to which the patient is now constantly exposed, was sought to be prevented by those means which have again and again been described: a warm, moist atmosphere in the apartment; frequent brushing out of the canula with fine pigeons' feathers; a woollen comforter saturated with bichloride or carbolic acid solution around the neck; instillations into the canula of a few drops of a two per cent. boracic acid solution or of chlorine water solution (1 to 8) every few hours, according as the canular respiration appeared obstructed or not; and the steam

atomizer. In spite of all these precautions, and although when the inner canula was removed, cleansed, and returned to its place, the suffocative attacks returned with increasing severity, it was found that the inner extremity of the canula had induced such an irritation of the mucous membrane of the trachea as to cause an annular crust to be formed, which could only be dislodged after removing the entire canula and entering the windpipe with a soft catheter.

There is, of course, nothing new about all this, and it is adduced only for the purpose of showing how necessary it is to have a man about the patient who will dare to remove the canula at once, in case there should appear to be imminent danger of suffocation from so simple a matter as occlusion by dried mucus.

Many cases will be found on record in which death occurred under these circumstances before the physician could reach the patient.

The rule in our cases was to wait, if possible, with the removal of the canula, until the physician could be present, because its reintroduction is not always a simple affair.

The diet was semi-solid, consisting of custards, gruels, etc.; and when even these gained entrance into the larynx, nutritive enemata of Leube-Rosenthal meat solution, eggs, and brandy were given, in order to avoid all danger of "Verschluckung's pneumonie." When the patient could swallow easily, Tokay wine was given in comparatively large quantity.

In two of the cases which I saw with the late Dr. G. Mandelbaum, of this city, the prostration for a few days following the operation was so great that inhalations of pure oxygen gas were resorted to with apparent benefit.

In from three to six days after the operation, when the child showed signs of returning health, attempts were at once instituted to restore the functional activity of the larynx by closing for a brief time the outer opening of the canula with the finger, or by partially corking it, and gradually increasing the size of the cork until it completely closed the outer aperture. This was not easy in every case, on account of the granulations around and in the fenestra, and in the trachea surrounding the inner opening of the canula; in such a case small semicircular or crescent-shaped pieces of granulation tissue were spontaneously expelled, and the obstruction removed.

When, with the canula completely closed, the child was able to take a fairly deep inspiration, to speak audibly, and to blow out a lighted candle held at a distance of four inches from the mouth, we removed the canula and applied adhesive strips over the wound.

The shortest time after the operation that the canula was removed was six days; the longest, twenty-eight days.

Granulations in the trachea, forming polypoid growths, and softening of the tracheal rings from too long a retention of the same canula, are dangers not to be overlooked at this period, and the canula should either be changed or its removal attempted at the earliest possible time. To describe the symptoms and course of each one of my cases would unduly lengthen this article. Of the ten cases that I have tracheotomized, three terminated fatally. One died on the fourth day after the operation from heartf-ailure, while turning around in bed; the second from clogging of the trachea and bronchi with diphtheritic membrane on the fifth day; and the third from septic intoxication twenty-four hours after the operation. The remaining seven are still living. The youngest patient operated upon was two years and three months; the oldest, seven years old.

In conclusion I would say that, in my opinion, too much stress cannot be laid upon the importance of skilful and painstaking nursing in the after-treatment, and that when this will be more generally carried into effect we shall hear of a greater percentage of successes after this operation.

THE TREATMENT OF HYDROCELE AND VARICOSE VEINS BY CARBOLIC-ACID INJECTIONS, ETC.[1]

By LEONARD WEBER, M.D.,

NEW YORK.

For many years I followed the routine of using Lugol's solution for the purpose of obliterating hydrocele. The procedure is often efficient, but always painful, followed by considerable local, and sometimes general, reaction. The folds of the testicle, and a good part of the scrotum, may slough away, if the fluid be forced between the membranes and not into the sac; but I have also seen some cases of moderate sloughing in consequence of the intensity of inflammatory reaction, although the operation was skilfully performed.

With injections of chloroform or alcohol for the above purpose I have had no experience; but as we became acquainted with the various uses of carbolic acid, it was natural enough that we should also test its power and convenience in setting up that degree of adhesive inflammation which would be sufficient to obliterate a serous sac or a varicose vein.

Case I.—In 1878 E. V——, aged twenty-six, came to me with a single hydrocele of probably traumatic origin that had been tapped a year before. The sac had refilled, and the patient was now ready to be operated upon. Having previously made up my mind that a solution of equal parts of carbolic acid and alcohol and water ought to be of sufficient strength to destroy the epithelial lining of the sac and obliterate the latter, I injected about three ounces of such a mixture, agitating the fluid for nearly three minutes before withdrawing it. The operation was done at my office, the patient experienced as good as no pain, and having replaced his suspensory bandage he rode home. Within the next forty-eight hours the hydrocele resumed nearly the size it had before the operation, but there was no pain, nor any other local or general disturbance. From about the fifth day on it began to grow smaller, and at the end of two weeeks had disappeared. It has not returned.

Case II. was that of I. B——, now seventy-two years of age. A large hydrocele developed in 1874; I tapped him five times up to 1879, the membranes of the sac remaining thin and soft. In March, 1879, I operated on him in the same way as above, and with the same satisfactory results.

Case III.—A. T——, aged forty-four, a liquor-dealer. I had relieved him of hydrocele of one side by injecting Lugol's solution some years ago. He came to me in April, 1881, with a hydrocele on the other side, and desired to have it tapped simply, as he was afraid to again undergo the pain and discomfort he had suffered after the first operation. He yielded to my persuasion as to the comparative painlessness and safety of the new method, and the result was in every respect as gratifying as in the other cases.

Case IV.—C. R——, aged forty-five, a mechanic. I cured him of a large and often-tapped hydrocele on his right side in 1868, by the radical operation. He has been troubled with hydrocele, of moderate size, on left side for a year or so. Evacuation of cystic fluid and injection of the above carbolic solution were made in May, 1883. In puncturing the sac a subcutaneous vein was cut by the trocar, causing considerable extravasation in the areolar tissue, swelling of the parts, and some pain and fever. Ice had to be applied for a few days to subdue inflammation, but no suppuration took place, and the final result was as good as in the other cases.

It stands to reason that carbolic acid, in common with all other means for injection, will not answer in hydrocele where the sac is hypertrophied to any considerable extent. The cyst in that case has the feel of a

[1] Read before the German Medico-Chirurgical Society.

stout rubber bag, is of oval shape when unilocular, and of more or less irregular shape when multilocular, by the formation of false bands in its cavity. Such cases need not always be old ones, as is shown by the history of the following: A young and otherwise healthy man came to me with hydrocele in 1880. It was of dumb-bell shape, of moderate size, tense, not transparent, and had developed after gonorrhœal orchitis fifteen months before. It had been tapped once. After making a free incision and evacuating about three ounces of yellowish and somewhat turbid fluid, the walls of the sac appeared to be one-third of an inch in thickness. A stout fibrous band drew the cyst walls together about the middle of the tumor. I broke down all the adhesions, scraped and washed the cavity thoroughly with sponges dipped in a ten per cent. solution of carbolic acid, and stuffed it with a pledget of lint smeared with unguentum iodoformi. The iodoform dressings were removed three times during the first ten days. Ungt. basilic. to stimulate granulations was substituted after that, and at the end of three weeks the cure was completed. The patient had some fever on the second and third days after the operation, but no more after that. In such and similar cases I have found the radical operation and antiseptic dressings the best and safest mode of treatment.

For the purpose of coagulating the blood in varicose veins and obliterating them by adhesive inflammation carbolic acid has proved to be a safe and efficient remedy in many cases. The first case in which I used subcutaneous injections of pure carbolic acid was that of L. S——, aged thirty-eight, a merchant, who came to me in 1878 with a markedly varicose condition of the entire territory of the saphena major of the right lower extremity. He was otherwise a strong and active man, but the pain and discomfort in walking caused by the increasing distention and pressure of the enlarged veins of the neighboring parts made it hard for him to attend to his business. Elastic stockings had given him no relief. I found four large sinuses beneath and to the inner side of the patella and at the popliteal space, which were exquisitely tender. I thought if I but succeeded in obliterating these the patient might be made comfortable otherwise by the judicious use of massage and elastic bandages. I tried Vidal's method by acute pressure. It failed to do what I wanted, but caused the patient some sleepless nights and much pain. I then injected four drops of carbolic acid into each sinus, entering the needle sideways and making compression at the proximal and distal end of the sinus until I felt that a soft coagulum had formed. Two sinuses were operated upon the first, and two on the next day, wet compresses and a bandage gently tied around the knee, and the patient kept in bed for a week. No unpleasant reaction took place. In the course of the second week the thrombi were flat and firm, and the sinuses became obliterated. With the help of a long elastic stocking Mr. S—— was soon able to be about all day long, without experiencing more than slight discomfort. I met him again in 1880, and learned that his leg gave him no trouble, but the stocking he had to have on when going about.

In treating hemorrhoids we must, of course, distinguish between external and internal ones. External hemorrhoids of small size may be obliterated by injecting a minim or two of pure carbolic acid, or, with less risk of sloughing, four or five minims of a fifty per cent solution of the acid.

A careful selection of cases of hemorrhoids suitable for the obliterating treatment by carbolic-acid injections is highly commendable. With small, tense, and moderately bulging tumors of this kind I have had barely good success; but the procedure was often painful, and not infrequently followed by inflammation. In a few cases gangrene of the injected hemorrhoid supervened, and the dead mass came away under antiseptic dressings without any unpleasant local or general consequences.

Phlegmon, abscess, and subsequent fistula in ano, in consequence of injections either too strong or applied in cases in which this mode of treatment was not advisable, have been seen, and I have personal knowledge of such a case which occurred not long ago in this city. The possibility of ascending thrombosis and pyæmia under similar circumstances cannot be denied. Altogether, the cure of hemorrhoids by carbolic-acid injections is a method which I believe to be neither as generally applicable nor so free from danger as it has been represented by some practitioners.

In operating it will be best to insert the needle about one-fourth of an inch from the base of the tumor, and push it through the sound skin directly forward into its central portion, taking good care not to spill any of the liquid along the track of the needle or at the point of entrance. This precaution I have found to be essential if we want to get obliteration of the pile by adhesive inflammation instead of seeing it slough away. The large and pendulous external hemorrhoids may be ligatured after incising their cutaneous parts, cut off, and the wound dressed with iodoform until the ligature comes away. Many such I have also clamped and cauterized with the Paquelin cautery to prevent hemorrhage and insure prompt and satisfactory healing of the wounds. In my experience this procedure has given invariably good and lasting results in all cases in which it was admissible.

Whether we employ the ligature or thermo-cautery in external or internal hemorrhoids, it is good practice to stretch the sphincter ani in a moderate degree before proceeding to operate. Such distention not only facilitates the operation, but also prevents subsequent pain and discomfort, and promotes the healing of the wound.

Carbolic-acid injections will not do for internal piles; they must be treated by the ligature, or the clamp and cautery, as described above.

I have the records of four severe cases of external and internal hemorrhoids, three in males and one in a female, every one of which had between five and eight hemorrhoidal tumors within and without the sphincters. They all showed the symptoms of anæmia to a considerable degree. Three of them were operated upon with the clamp and cautery, one with the ligature, and they all got well without secondary hemorrhage or other unpleasant symptoms.

25 West Forty-sixth Street.

An Improved Method of Operating for Cleft Palate.—A correspondent writes to *The Lancet*, November 7, 1885, concerning what he considers a great improvement in the operation for cleft palate. Hitherto great difficulty and not a little danger have arisen from hemorrhage during the operation, necessitating frequent and very skilful assistance, periodical discontinuation of the anæsthetic, and distinct intervals in the performance of the operation. In addition to these, other and minor troubles are experienced. All these difficulties may be avoided, and the operation rendered perfectly safe and easy, by the simple process of inversion as applied to the head only. This can easily be attained by bringing the patient's shoulders well up to the end of the operating table, and allowing the head to hang over the edge in the fully extended position. In this position the roof of the mouth would be horizontal or slightly inclined downward toward the operator, who should stand at the head of his patient. The anæsthetic is given through the nose by a small tube, and is quite out of the way of the surgeon. Only one assistant is required, who should stand to the left of the operator. In paring the edges no change of hands is required, but the corresponding hand should be used in elevating the tissues of the hard palate and in passing the sutures. Under these circumstances no blood can enter the larynx or œsophagus, the palate remains unobscured by blood, and whatever hemorrhage occurs finds its way into the nasal cavities, and at the conclusion of the operation may be emptied by simply turning the patient's head to one side.

Clinical Department

PROBABLY A DERMOID CYST.

The following curious case is reported by Dr. F. L. Santway, of Theresa, N. Y.: A farmer, twenty-one years of age, weighing about two hundred pounds, while driving an empty hay-wagon one day in July, 1881, was thrown down, by a sudden start of the horses, to the bottom of the wagon. He fell on his back, his hips striking one of the bed-pieces of the rack, and, the horses becoming unmanageable, he was carried about a quarter of a mile in this position, with his back jolting against the piece of timber. From that time to the present he has suffered severely from pain over the region of the sacrum and coccyx. In July of this year he discovered a slight discharge from a small opening three and one-half inches above the anus, directly over the spine. Examination showed three small openings, the size of a pin-head, from which there was a thin, sanious, ichorous discharge. The openings were about three-quarters of an inch apart and were found to lead to a single cavity one and three-quarters of an inch below the surface. Thinking that there might be a detached spicula of bone, Dr. Santway incised the integument between the three apertures, when, to his surprise, instead of finding diseased bone, he discovered the cavity half filled with hair. There were about one hundred and fifty of these hairs, ranging in length from one-half to one inch. These were removed with the dressing-forceps, and the cavity was syringed out with carbolized water. The wound is now nearly healed, and the pain across the hips, from which the patient had suffered for four years, is rapidly diminishing. [It is not improbable that this patient had a congenital dermoid cyst, which is sometimes found in the sacral region, in which inflammation was excited by the injury.—Ed.]

WHAT WAS IT?

Dr. Leonard White, of Uxbridge, Mass., sends us a report under the above caption of two cases occurring recently in his practice. The first case was that of Robbie H——, eight years of age, who, when first seen, had been unconscious for eighteen hours and had passed no water for thirty-six hours. He had been complaining of headache and general malaise for two weeks. He had been vaccinated shortly before. The temperature was 104° F., pulse 120, rising to 136 in a short time, pupils contracted, breathing stertorous, abdomen somewhat tympanitic. Three pints of water were drawn from the bladder. The vaccinated arm was red and ulcerated, but there was no glandular swelling in the axilla. An enema of twenty grains of quinine in milk was ordered, and hypodermic injections of digitalis and brandy were given. This treatment, with carbonate of ammonia internally and cold applications to the head, was continued until the patient died, four days later. The abdomen became retracted, the pulse grew more rapid and feeble, and respiration was more and more labored and hurried. There was complete unconsciousness during all this time, and the prick of the hypodermic needle caused no wincing. A certificate of death from malignant typhoid fever was reluctantly given. The second case was that of Charles H——, twelve years old, who had been vaccinated two and one-half weeks previously. He felt well up to the day before being seen, when he complained of headache. At the time of Dr. White's visit the boy was unconscious, with a temperature of 104°, pulse 120, respiration very shallow and rapid. From the bladder was drawn a large quantity of urine heavily loaded with urates, but containing no albumen. The pupils were contracted, and the abdomen was only slightly tympanitic. Stimulants were given hypodermatically and by enema, and sinapisms applied to the neck and spine. Urine in large quantity was drawn every six hours. The patient did not rally, however, and died the following day. The consulting physician gave a certificate of death from septicæmia following vaccination, to which Dr. White would not agree, although he had not vaccinated either of the children. An autopsy could not be obtained. The writer would be glad to have an explanation from others who may have met with similar cases in their practice.

COCAINE IN DENTAL SURGERY.

Dr. J. H. Martindale, of Minneapolis, Minn., writes that he has had very satisfactory results with cocaine in his dental practice. Before proceeding to the extraction of incisors or bicuspids or their roots, he dries the adjacent portions of the gums and rubs them with a five per cent. oleate; then he introduces a hypodermic needle at the free edge, passing it for a distance of half an inch parallel to the roots of the tooth to be extracted, and injects two or three minims of a four per cent. aqueous solution. The tooth may then be pulled with little or no pain. In chronic alveolar abscess with fistula, the carious bone may be gouged away without exciting pain by introducing the hypodermic needle as far as possible into the sinus and injecting three or four minims of a four per cent. solution. The sensitiveness of the mucous membrane investing the parts near the soft palate, causing the patient to retch during manipulations about the back teeth, may be overcome by bathing the parts with the four per cent. solution. Dr. Carl Tuttle, of Berlin Heights, O., writes upon the same subject. He thinks that failure is often due to a too sparing use of the anæsthetic. He inserts the point of the hypodermic needle one-quarter of an inch from the free margin of the gum and passes it well down to the roots between the gum, and the alveolar process. He injects in this way seven minims of the four per cent. solution on each side of the tooth to be extracted, and allows eight minutes to elapse before using the instruments. He says that he has had very satisfactory results in dental practice from cocaine employed in this way.

CONCEPTION WHILE THE UTERUS CONTAINED A PLACENTA.

Dr. W. M. Trow, of Northampton, Mass., gives an account of the following case: "Mrs. ——, a fleshy woman, and the mother of three children, regular in her periodicals except during pregnancy, passed her period in February, 1885. In March she was normally unwell, and was regular till August, which she passed. In September she again menstruated. In October she was taken with considerable flow and severe pain, which continued for twenty-four hours, when I was called to see her. On my arrival I found a three months' fœtus, which she expelled just before my entering the house. The placenta was partially detached, and occupied the mouth of the uterus. Under the influence of ergot it came away in a short time in a normal condition. The following day she was feeling well; the flow as usual in such cases. Four days after I was again called, and found that she had been flowing for twenty-four hours, and suffering severe pain most of that time. An examination revealed the mouth of the uterus open enough to admit two fingers, and occupied by a fleshy mass which was firmly attached to its fundus. I gave chloroform and introduced my hand into the vagina, when I was able to detach the mass, which was at once expelled. It proved to be a placenta as large as is usually found in a conception of four or five months. Pain and flowing at once ceased, and she made a fair recovery. This was a unique case with me in an experience of some thirty years."

Progress of Medical Science.

Hydrastis in Dyspepsia.—In *The Lancet*, November 7, 1885, Mr. Auld directs attention to the value of hydrastis in small doses in certain forms of dyspepsia. Given in drop doses of the tincture (made with proof spirit) three or four times daily, between meals, is the mode of administration he would recommend. Larger doses often produce aggravation of the symptoms and diarrhœa. In his experience there are three kinds of dyspepsia to which it is applicable. The first is the dyspepsia of females, characterized mainly by pain and sinking at the epigastrium, nausea, and constipation, and associated with general debility, nervousness, wandering pains, and possibly leucorrhœa. The subjects of this variety are often intolerant of large doses of bismuth and other orthodox remedies; but, unless marked anæmia exists, they will speedily regain health and strength under the influence of hydrastis, which acts like a specific. The second form of dyspepsia which is often greatly relieved by this drug is that associated with certain constitutional diseases, particularly phthisis and malignant disease. Lastly, it is of signal benefit in the dyspepsia resulting from the abuse of drugs and alcoholic stimulants.

Cocaine in the Treatment of Hydrocele.—A correspondent of *The London Lancet* writes as follows concerning the above: "We all admit the great and frequently agonizing pain usually produced by the injection of tincture or solution of iodine, diluted or undiluted, in the radical cure of hydrocele of the tunica vaginalis; and many methods are employed to alleviate this pain, from simple compression of the cord to the production of general anæsthesia. To the flood of literature concerning the applications of cocaine and its salts I beg to add a note as to the use of the hydrochlorate in alleviating what is more than a discomfort in the treatment of the common affection under discussion. After withdrawal of the fluid from the hydrocele sac, it is easy to inject thereinto a drachm, more or less, of a five per cent. solution of the salt named, allow it to flow over the interior, and after five to ten minutes inject the selected iodine preparation, which will not give rise to any pain until an hour or more has elapsed, which pain, usually not severe, if necessary, can be controlled by the exhibition of a morphia suppository, or by some similar means. The use of the cocaine salt in this manner further allows kneading of the sac after the iodine injection, which kneading Davy and others have strongly insisted on; and while, on the one hand, paralysis of the sensory nerves of the serous membrane can, as Cohnheim showed, have practically no retarding influence on the development of the inflammation, on the other, no evil effects can follow the absorption of a quantity of cocaine so far below a toxic dose. Cases thus treated progress, with the exception of the pain, precisely as those in which no cocaine is employed."

The Etiology of Dupuytren's Contraction.—Dr. Lange reports the case of a woman who had for years had a contraction of the palmar fascia of both hands, so that the tip of the ring-finger of either side was drawn into the palm. This woman had an apoplectic seizure, and from the moment that paralysis of the left side appeared, the ring finger became fully extended and so remained, the corresponding digit on the right side still being firmly flexed. The deep folds of skin in the palm of the left hand became smoothed out, leaving scarcely any traces to show where the creases had been. The author regards this case as an evidence that Dupuytren's contraction has its origin in the central nervous system, a theory rendered more probable also by the fact that the affection is usually symmetrical. If the contraction in this instance had been due to disease of the muscles, fascia, or terminal nerve-filaments, it would hardly have been so suddenly relaxed upon the appearance of central paralysis. He thinks also that it points to nerve-stretching or resection as the proper mode of treatment. —*Allgemeine Medicinische Central Zeitung*, October 21, 1885.

Copper in the Treatment of Scrofula.—From the results obtained in a large number of trials, Dr. Du Moulin is led to recommend the salts of copper in the treatment of various scrofulous manifestations. He asserts that they are efficacious in the cure of indurated and suppurating glands, in cutaneous affections, and in ophthalmia and keratitis due to scrofula. For a child from one to four years of age he orders a solution of from four and a half to six grains of sulphate of copper in three ounces of syrup, of which four teaspoonfuls are given daily.—*Rivista Clinica*, No. 9, 1885.

Inhalations of Defibrinated Blood.—Regarding on the one side, the possible dangers of transfusion, and on the other, the tolerance of liquids by, and their rapid absorption through, the respiratory mucous membrane, Dr. Fubini was led to test the value of inhalations of defibrinated blood (*Rivista Clinica*, No. 9, 1885). He caused healthy individuals to inhale, by means of an ordinary atomizer, about three ounces of a mixture of twenty parts of defibrinated blood in eighty parts of a strong solution of common salt. The inhalations were well borne by the larynx, and caused no change in the pulse, temperature, or respiration. In anæmic individuals, after repeated inhalations, the author noted a marked improvement in the general condition, and also a relative increase in the number of red blood-corpuscles.

Borated Vaseline in Erysipelas.—Dr. Romit speaks very highly of boracic acid in vaseline, one part to twenty, as an application to the inflamed skin in traumatic erysipelas. It has an advantage over certain other applications in that it causes no discoloration, and does not mask the redness of the skin, so that the progress of the disease toward recovery can be readily observed. The redness and tumefaction rapidly disappear, the pain is quieted, and a cure is obtained within three or four days. The application is made over the affected part, and for some distance around over the healthy integument, and is repeated morning and evening.—*Rivista Clinica*, No. 9, 1885.

Malarial Amaurosis.—Dr. Rombro reports in the *Russkaya Meditsina*, No. 20, 1885, the case of a peasant, who became suddenly blind without any apparent cause. On admission to hospital two days later, no ocular lesions were discoverable, but the man was found to be suffering from malarial fever and to have hypertrophy of the spleen. He was given quinine daily, and at the end of a week the sight began to return, becoming normal a few days later. Dr. O. Petersen reports in the *Deutsche Medicinal-Zeitung*, No. 77, 1885, a precisely similar case which came under his observation during the Turko-Russian war, in which vision was restored in a few days by means of large doses of quinine.

Vomiting of Pregnancy treated by Artifical Feeding.—Dr. Brünniche reports in the *Hospitals-Tidende*, No. 29, 1885, the case of a pregnant woman who suffered from uncontrollable vomiting. After trying many things without success, the author obtained a cure by feeding his patient through a tube introduced into the œsophagus, but not into the stomach. Milk, broth, powdered beef, and other materials were introduced in this way and retained on the stomach, but as soon as the patient attempted to swallow the vomiting began again. At the end of three weeks, however, the vomiting was permanently controlled and the patient was able to take food in the ordinary way.

Syphilis, Ataxy, Cardiopathy.—The clinical and pathological labors of many authors attest the not infrequent association of heart disease with locomotor ataxy. Charcot and Vulpian some years ago pointed out the association; but Berger and Rosenbach. in 1879, gave more precise information on the subject. In seven cases of ataxy observed by them an insufficiency of the aortic valves was observed. MM. Grasset, Jaubert, Teissier, Weber, and others have written on the significance of this combination of diseases. A *résumé* of the subject is published in the *Lyon Médical*, in an article contributed by M. Bouveret. The chief question that occupies his attention is the relation of syphilis to locomotor ataxy and to cardiopathy. In some cases the cardiac disease can only be regarded as the result of rheumatism or atheroma, and its coexistence with locomotor ataxy must be looked upon as a coincidence. On the other hand, disturbances in the nervous system may originate derangement of the heart. Lastly, there is the possibility of the dependence of the aortic disease on syphilitic processes, which have also been operative in the causation of tabes dorsalis.

General Softening and Facial Ecchymosis.—Dr. Klippel describes an interesting combination of cerebral disease with facial extravasations of blood. The patient was a woman sixty seven years of age, whose previous history was very imperfect, owing to her abnormal mental condition as well as to her lack of friends. Although there was no actual paralysis, and no rigidity of the legs, yet walking was impossible for her. All the limbs were wasted, and the fronts of the legs exhibited a pigmentary marking. The knee-jerks were absent, and there was incontinence both of urine and fæces. The arteries of the limbs were markedly atheromatous, and though the heart-sounds were altered from the normal there was nothing pointing to gross valvular lesion. While the patient was in this condition of dementia, and at the end of two months after her admission to the hospital, ecchymosis of the face supervened. It was certain that she had sustained neither a fall out of bed nor any sort of injury. The sanguineous extravasation began at the inner canthus of the left eye, and gradually spread thence. Some hours later a like condition came on in the inner canthus of the right eye. At the end of two days the whole of the upper half of the face became infiltrated with blood; very slowly this ecchymosis passed through the various stages of a fading bruise, and finally disappeared, with the exception of two symmetrical ecchymotic spots on the anterior part of each thigh. There were no other signs of purpura, either cutaneous or mucous. Signs of scurvy were wanting, and there was no fever. The reporter discusses the possibility of the ecchymosis being due to the influence of the nervous system, but inclines to the view that the causes were several, though chiefly vascular and nervous. Many cases are now on record of blood-extravasations occurring in the course of diseases of the nervous system, and this clinical experience, together with the facts of experimental pathology, seems to place beyond doubt the potency of the nervous system to rupture vessels.—*The Lancet*, October 31, 1885.

Scarlatinal Rheumatism.—The nature of the so-called scarlatinal rheumatism has long been a matter upon which there has been a considerable variance of opinion. On the one hand, it has been contended that the poison of scarlet fever, working in a subject prone to rheumatism, may be the exciting cause of an attack; in other words, that scarlatinal synovitis only occurs in the rheumatic. On the other hand, it is affirmed that this so-called rheumatism is only a manifestation of the scarlet-fever poison localized in the joints, or that it is in reality a form of mild septicæmia. Different writers have advocated various views; thus, Trousseau, Betz, and Huttenbrenner speak of this affection as indistinguishable from acute rheumatism, and most of the English text-books, including Bristowe, take the same view. There is, however, much to be said in favor of the opposite side, for it must be admitted that scarlatinal synovitis presents a picture which differs in many ways from acute rheumatism. One of the difficulties in settling the question arises from our want of knowledge of the pathology and etiology of the rheumatic state. The term is applied in an exceedingly comprehensive way, and covers an extensive ground. Thus, we have a "fibrous," a "muscular," a "gonorrhœal," a "gouty," as well as "scarlatinal rheumatism," all more or less differing in their chief symptoms, and perhaps also in their pathology, from acute or chronic rheumatism. In typical attacks of the scarlatinal variety, the joint pain is first complained of at the end of the first week, when the rash has nearly disappeared and desquamation commenced. The temperature, which has perhaps nearly reached normal, again rises when the joint-pain is complained of. The synovitis is especially apt to affect the finger-joints and wrists, then perhaps the knees and shoulders. It is not uncommon for the joints of the cervical vertebræ to be attacked, and also the synovial membranes lining the extensor and flexor tendons of the fingers, the palms or backs of the hands being swollen and tender. There is pain on movement, the joints are often red, swollen, less often distended with fluid. As a rule, the pain and tenderness quickly disappear in the affected joints, other joints becoming attacked, but the attack is fugitive, and in three or four days the attack is over and the patient free from pain, which rarely returns. As Trousseau has well reminded us in his lectures, "It is a singular eccentricity of scarlatinal rheumatism that it rarely assumes a formidable character; it is more localized, but less likely to return than ordinary rheumatism. When it has once left a joint it seldom comes back to it—generally it goes away quickly and spontaneously, without requiring any treatment." Another important point must be borne in mind, that while pericarditis occasionally occurs, endocarditis is very rare. It is, then, to this disease that Henoch, Jaccoud, Bokai, and many, especially German writers, refuse the name of rheumatism and prefer that of scarlatinal synovitis. There are unquestionably some facts which strongly support their objections. In the first place, this complication is far more common in some epidemics than in others, a fact which would point to the synovitis as being connected with the scarlatinal poison, rather than to the rheumatic diathesis of the patient. Then the attacks are fugitive and are rarely followed by a relapse, while in true rheumatism, as is well known, relapses are very common. Further, affections of the heart are rare, occurring very much less frequently than in acute rheumatism, at least when it affects children. Suppuration occasionally occurs in or about the joints, and purulent pericarditis is sometimes present in the fatal cases. In considering the question it is important to remember that synovitis occurs in other diseases, more especially those where some inflammation of a mucous membrane or a purulent discharge exists—such, for instance, as in puerperal fever, diphtheria, gonorrhœa, and also in ulcerative endocarditis. There is but little doubt, however, that true rheumatism does sometimes occur during convalescence from scarlet fever or diphtheria. These attacks supervene at various periods after the fever, are often severe, are accompanied by cardiac complications, effusion into the joints, acid sweats, and a tendency to relapse. Whether these attacks are simply coincidents, or the result of the accumulation in the system of waste products during scarlet fever, it is not easy to say. It seems very probable that some, at least, of those who have written on this question have been, in reality, observing different kinds of attacks, the one observing the synovitis, which complicates the fever the other, true rheumatism, supervening during convalescence. The whole series of joint-affections, complicating other diseases, deserve the most attentive study on the part of every practitioner, inasmuch as out of such study light might be thrown on the etiology of acute

rheumatism, which, in spite of many investigations and hypotheses, still forms a dark corner of clinical medicine. With regard to the suppurations which occur in or about the joints during the course of scarlatina, there can be little doubt that they form part of a general pyæmia, and on the post-mortem table abscesses may be found in the lungs and kidneys, due, doubtless, to septic embolia, derived from suppurating cervical glands or a sloughing throat. Some, however, of these cases which seem to suffer from a milder form of septicæmia recover after the evacuation of pus from the joints.—The *Provincial Medical Journal*, November 2, 1885.

The Treatment of Burns.—Dr. Meurisse speaks very highly of goldbeaters' skin as an application to burns. He says that it never becomes adherent to the skin as other forms of dressing do, the pain and inflammation are much less marked, and the wounds heal much more rapidly. The goldbeaters' skin may be washed with cold water at each dressing and can be used again and again. The liniment or other applications may be made directly to the skin and covered with the tissue. The same substance may be used in dressing blisters after the application of a vesicatory.—*Revue Médicale*, October 3, 1885.

Pathogeny of Pulmonary Emphysema.—Most diseases and degenerations have at one time or another been attributed to trophic changes, the result of disturbed innervation. Dr. Brown-Séquard believes that nervous disturbances in the pneumogastric play a part in the production of pulmonary emphysema (*The Lancet*, October 17, 1885). He does not deny the agency of mechanical forces, but he thinks they have been overrated. Neither forced inspiration nor energetic expiration during closure of the glottis has a preponderating influence in the genesis of emphysema. On the contrary, it is sufficient to excite the vagi as soon after death as possible in order to produce emphysema. The same result is obtained whether the post-mortem excitation be made at the medulla oblongata, at the cervical pneumogastric, or along its terminal branches. In opposition to Serres, it is asserted that stimulation and disease of the pons Varolii only exceptionally induce emphysema, though they are much more effective as causes of pulmonary apoplexy. The nearer the excited area of the pneumogastric is to the lung, the more marked is the emphysema. As of clinical bearing on the experimental question, Dr. Brown-Séquard refers to the development of emphysema with the first attack of genuine nervous asthma. It is impossible, he argues, that a few short hours of dyspnœa could develop so much emphysema. M. Laborde remarked, in the discussion on Brown-Séquard's paper, that among the decapitated emphysema was frequent. This circumstance is regarded as confirmatory of the opinions held by Brown-Séquard.

Fatal Cystitis Apparently Due to Phimosis.—Dr. Sadler, in *The Lancet*, October 17, 1885, reports the following case: A man aged seventy-seven was admitted to a hospital, suffering from partial retention of urine. His story was that he had had a very long prepuce all his life, but it had given him no inconvenience. Though for some years subject to frequent micturition by day and night, he had never been aware of any difficulty in expelling urine. He had been in failing health some months, and for several weeks his foreskin had been swollen and he had been unable to pass more than a few drops of urine at a time. He was a very feeble old man, and was very much collapsed on admission. On his hands and feet were numerous small, dry, brown fissures, as if from commencing dry gangrene. The prepuce was very long, œdematous, hard, and inflamed. It barely admitted a small probe. Bladder much distended. A fine curette was passed into the prepuce, and it was divided to its base. Then a No. 12 English silver catheter was passed without any obstruction into the bladder, and several pints of intensely fetid purulent urine withdrawn, with some decomposed clots. The bladder was washed out. The washing was repeated several times during the next twenty-four hours, but he never rallied from his collapse, and died quietly next day. No autopsy was permitted. There were no calculi in the perpuce, nor could any be felt with a sound in the bladder.

The Cause of the First Sound of the Heart.—An interesting note on the cause of the first cardiac sound, by Dr. Gerald Yeo, and Dr. J. W. Barrett, has appeared in the *Journal of Physiology*. Opinions, as is well known, have varied considerably on this point. Some observers, as Halford and Billing, looking at the relative size of the auriculo-ventricular and semilunar valves, have held that the sudden tension of the former is sufficient to produce the first sound of the heart. These observers point to the fact that just as the act of hooking back one semilunar valve abolishes the second sound, so the same act of hooking back one auricular valve, or the incompetence of the valve as a whole, impairs or abolishes the first sound; and they also point to the fact that the tracing of a cardiac contraction is a single contraction, and not a tetanus of the muscular tissue. Many careful experimenters, however, maintain that the muscular sound must be regarded as an element in its causation, and insist on the greatly increased volume of the sound in cases of cardiac hypertrophy. Drs. Yeo and Barrett's experiments originated in a difference of opinion between them on this point, each being desirous of persuading the other of the soundness of his views. To determine the question, a large cat and an active mongrel bull-terrier were chloroformed and subjected to artificial aspiration, and the cardiac sounds were then carefully listened for by each disputant, as well as by some independent observers, after the thorax had been opened by an extensive medial incision without injury to the pericardium. The veins were then compressed, and all noted that the sound became gradually slightly diminished, but did not become inaudible, the tone remaining distinct as long as the heart continued to beat. In the case of the dog, the same phenomenon was observed even after the heart was removed from the body, and the same was noted in the ventricle when removed below the valves. The authors therefore arrived at the conclusion that a definite aud characteristic tone, similar in quality to the first sound, is produced by the heart-muscle, under circumstances that render it impossible for any tension of the valves to contribute to its production.—*The Lancet*, October 31, 1885.

Obstruction of the Right Auricle by a Hydatid Cyst.—A curious case has been recorded by M. Ignatieff. He operated on a young peasant for hydatid of the liver. An incision six centimetres long was made in the linea alba. The peritoneum was divided and stitched to the integuments by points of suture. The operator was drawing the cyst forward to the abdominal wall before puncturing, when the heart of the patient suddenly ceased to beat; this was followed by stoppage of respiration, leading to asphyxia and death, despite tracheotomy and faradization about the diaphragm. At the autopsy an echinococcus, doubled up on itself, was found to obstruct the last part of the vena cava inferior; it projected into the right auricle. The bladder, when unrolled, measured ten centimetres across, and had a thickness of from three to four centimetres. Neither the auricle nor the ventricle contained any blood. The vena cava near the liver was perforated with a round opening about one centimetre in diameter; this aperture had obviously been caused by the erosion of the wall from the neighboring hydatid cyst. According to M. Ignatieff, the rupture was effected at the operation, and a hydatid vesicle, becoming engaged in the torn vessel, was carried upward, and so caused arrest of the heart.—*The Lancet*, October 17, 1885.

ADONIS VERNALIS.—Dr. Gaetano Traversa has made a most exhaustive study, both clinical and experimental, of the physiological and therapeutical action af adonis vernalis, the results of which he has published in detail in the *Giornale Internazionale delle Scienze Mediche*, Nos. 8, 9, and 10, 1885. He says that he has been led by these trials to regard the drug as one of the greatest value, and he does not hesitate to call it the best cardiac tonic which we possess, and one which may render the greatest service in the treatment of chronic heart disease. He thinks it more certain in its action than digitalis, and preferable to the latter drug also from the fact that it is rapidly eliminated from the system and never exhibits a cumulative action, and, furthermore, does not disturb the cardiac function when given in large doses. Adonis unites to rapidity of action and certainty of effect the most excellent and desirable quality of innocuousness. It possesses, also, marked diuretic properties.

ACUTE NEPHRITIS COMPLICATING PULMONARY TUBERCULOSIS.—Dr. E. Marchiafava describes a case of acute nephritis, occurring in a young man affected with phthisis, with a cavity in the lung, which appeared two weeks before death without any apparent cause. The kidneys were found to be increased in volume, softened, with subcapsular hemorrhages and dilated glomeruli. Microscopical examination showed similar lesions to those present in the graver forms of post-scarlatinal nephritis. Numerous sections of the kidneys were made in the search for micro-organisms, but although various kinds of staining were employed, neither tubercle bacilli nor other forms of microbes were found. This case would add weight to the belief that grave forms of acute nephritis may occur in the course of pulmonary tuberculosis which are not due to the presence of the tubercle bacillus or of any other species of micro organisms. It is simply a toxic nephritis, caused by certain products elaborated in the pulmonary cavity and carried by the circulation to the kidneys, setting up there inflammatory action.—*Gazetta Medica di Roma*, October 15, 1885.

FRAGILITAS OSSIUM IN SYPHILIS.—Many writers have referred to brittleness of the bones as of peculiar frequency in syphilis, but the cause of this change in their structure has not been satisfactorily explained. With a view of elucidating the subject M. Charpy has recently made a careful examination of the bones of several cadavers which presented evidences of syphilitic disease. He found that he was able, with a very slight degree of force, to snap the fibulæ, although to outward appearances their structure was unchanged. The bones were of normal thickness, and microscopical examination gave no evidence of change. Chemical analysis showed the normal relation between the organic and inorganic constituents, but of the latter there was a diminished percentage of fluoride of calcium (1.99 instead of 2.43 per cent.). Dr. Charpy regarded it, therefore, as possible that the abnormal fragility might depend upon a deficiency in the bones of fluoride of calcium.—*Deutsche Medicinal Zeitung*, November 2, 1885.

THE TREATMENT OF CHOLERA INFANTUM.—In an interesting paper upon "The Disproportion between the Calibre and Contents of the Vessels in its Relation to Etiology and Therapeutics," read at the Fourth Congress of German Physicians, Dr. E. Meinert, of Dresden, endeavors to show that the great danger to life in cholera infantum and other similar affections is in paralysis of the heart. A reduction in the contents of the blood-vessels, and a consequent disturbance of relation between the calibre of the vessels and the amount of blood contained in them is brought about, he says, not only by hæmorrhage but also by a rapid and extreme loss of watery fluids, such as occurs in several diseases. To these affections belong sunstroke, Asiatic cholera, cholera nostras, and cholera infantum, all of which are accompanied by a more or less rapid excretion of fluids. Death in these diseases, Dr. Meinert states, is due to cardiac paralysis induced by incomplete filling of the vascular system. His treatment, therefore, consists in the exhibition of as much water as the patient is able to swallow. He opposes strenuously the teachings of those who advocate withholding all food and drink for a period of six to ten hours, and says he can regard the recovery of a child with cholera infantum so treated as nothing short of a miracle. But fortunately the mothers of these little patients seldom have the heart to refuse their plaintive prayers for drink, and it is because they disobey the physician's orders, he thinks, that the children do sometimes recover. He gives clear water, tea, or very diluted milk, in repeated doses, and if the child throw it up he gives him some more to swallow, maintaining that in this way the tissues get a little water, and the stomach seems to acquire a tolerance. In a very short time, he affirms, this mode of treatment brings about recovery. The vessels become filled again, the vomiting and diarrhœa cease, and the life of the infant is saved.

KAVA IN GONORRHŒA.—This drug is recommended by Dupony and Gubler as almost a specific in the treatment of gonorrhœa and leucorrhœa. The active principles of the plant are a resin and a crystalline substance called by Gubler kavaïne. The administration of kava in gonorrhœa increases the urinary secretion, reduces inflammation, and quiets pain. It has the advantage over balsam of copaiba in that it has a pleasant taste, and does not affect the stomach unpleasantly. The plant, as is known, is a native of the islands of the Pacific.—*Deutsche Medicinal Zeitung*, November 2, 1885.

ALBUMINURIA IN ACUTE ARTICULAR RHEUMATISM.—In a recent thesis Dr. Chéron details the results of certain investigations which he has been making concerning the condition of the kidneys in acute articular rheumatism. He found albumin in the urine in about forty per cent. of the cases examined. Its presence is due, he thinks, to a passing renal congestion, an ordinary mild form of nephritis, or, occasionally, to renal embolism. The existence of albuminuria, he says, offers no contra-indication to the continued exhibition of sodium salicylate.—*Archives Générales de Médecine*, November, 1885.

OVARIAN HERNIA.—Professor Andrea Ceccherelli relates the case of a woman, thirty-eight years of age, who entered the hospital on account of a swelling which had appeared the evening before in the right inguinal region at the same time that the menses appeared. Examination showed a small tumor, a little larger than a walnut, movable, and but slightly painful on pressure. Herniotomy being performed, the body was found to be an ovary. The organ was returned with some difficulty, but the patient made a good recovery, and was discharged at the expiration of a fortnight. Boinet has collected the statistics of nine cases of this sort in which ablation of the ovary was practised, with the result of a cure in eight of them. But Dr. Ceccherelli advises oöphorectomy only in those cases of ovarian hernia in which there are plain indications of disease in the organ at the time of the operation. And such evidence of pathological changes is present, he says, only in exceptional cases, so that, as a rule, an endeavor should be made to return the ovary intact into the abdominal cavity.—*L'Union Médicale*, October 20, 1885.

THE DANGER OF SUBMUCOUS INJECTIONS OF CHLOROFORM.—Dop and Guillot have advised the injection of five or six drops of chloroform beneath the mucous membrane of the gums for the relief of toothache. But Blocq asserts that this procedure is not free from danger, and relates a case in which it was followed by extensive and painful swelling of the face, with necrosis of the mucous membrane of the upper lip and gum, resulting in prolonged suppuration and superficial necrosis of the jaw.—*Centralblatt für Chirurgie*, October 31, 1885.

The Foveola Coccygea.—This is the name given by Eckert to a depression in the skin sometimes found in the region of the coccyx. In an article in the *Centralblatt für Chirurgie* for October 31, 1885, Dr. O. Madelung says that his attention was first called to the existence of such a depression in the case of a boy with a pelvic abscess, in whom the foveola at first suggested the cicatrix of an old sinus. He learned, however, that there had never been any suppuration from this part, and further investigations showed that such depressions were by no means of great rarity. This depression indicates the position of the *glabella coccygea*, a small spot on the skin, near the junction of the last sacral and first coccygeal vertebræ, which becomes visible about the middle of fœtal life. The spot is uncovered with hair, and the skin is thinner than that of the neighboring parts. It is difficult to distinguish the glabella in the infant, but in the new-born it is often very distinct, as it is hairless, while the surrounding parts may be thickly covered with lanugo. This part is not infrequently also found as a crescentic or funnel-shaped dimple, and in such cases the depression or foveola remains after the glabella is no longer distinguishable. A knowledge of the possible existence of this anomaly may be of practical value. The author mentions the case of a man who had noticed pus-stains on his linen, and whose physician, on examination, discovered what seemed to be a sinus in the region of the coccyx. A probe failed to detect dead bone, but nevertheless this was supposed to be the cause of the discharge, and an operation was proposed. Madelung found, however, that the supposed fistula was merely a deep foveola, and the formation of pus was occasioned by an eczematous inflammation of the skin. Appropriate treatment was followed by a cure of the eczema. In a case of breech presentation the accoucheur felt a foveola and supposed it was the anus, while the anus he mistook for the vulva, and accordingly prophesied the birth of a female infant. He was somewhat chagrined to find a boy.

Quadruple Pregnancy.—Dr. Castañeda y Campos reports in the *Gazette de Gynécologie* for November, 1885, the case of a woman, twenty-eight years of age, who was delivered at the sixth month of four children. Three were males and one female; one was still-born, while the others lived from one to thirteen hours after birth. There were three distinct placentas, one being common to two fœtuses, and these were the most feeble and shortest-lived of the four, although they were the largest. The children died in the order in which they were born, the first being still born, while the fourth lived for thirteen hours. It would thus seem as though the few extra minutes of intra-uterine life had given the later ones a greater degree of vitality, enabling them to survive by several hours the first-comers. The mother suffered from phlegmasia alba dolens, but recovered promptly under appropriate treatment.

The Kidney in Diabetes.—In a recent work upon "The Kidney in its Relations to Diabetes," Dr. Inglessis states that functional hypertrophy of this organ is the most common lesion found associated with glycosuria. The kidney is increased in volume, and the cells of the convoluted tubules are markedly hypertrophied. True inflammation supervenes only after the disease has existed for a considerable period, and when present it usually assumes the form of parenchymatous nephritis. *Le Progrès Médical*, October 3, 1885.

Cocaine in Sea sickness.—Dr. W. Otto, surgeon of the steamship Ems, of the New York and Bremen Line, publishes in the *Berliner Klinische Wochenschrift*, of October 20, 1885, the results of his experience with cocaine hydrochlorate in the treatment of sea-sickness for the five months, from May to September, inclusive. The drug was given by the mouth in aqueous solution in doses of $\frac{1}{4}$ to $\frac{1}{3}$ grain, not oftener than three times a day. It was given only to adults and never hypodermatically. By means of this the vomiting was controlled, and nausea quieted; usually, also, a quiet and refreshing sleep followed, so that some of the patients supposed that they had taken morphine. In some cases, however, the drug failed to give relief, and the patients remained sea-sick until the end of the voyage.

The Number of Bacilli in the Sputa of Phthisical Patients.—Dr. Zenkevich, of Kieff, formulates the following conclusions from the study of a large number of observations: 1. The quantity and quality of the expectorated matters have no influence upon the number of bacilli therein contained. 2. The assertions of Balmer and Fraentzel and of Pfeiffer that the bacilli are most numerous during the last days of the patient's life are far from being correct. 3. The quantity of bacilli in the sputa is not proportional to the extent of pulmonary tissue involved. 4. It bears a direct relation to the degree of fever, and this depends upon the destructive rapidity of the disease. 5. The bacilli do not grow primarily in the purulent secretion and penetrate thence into the lung tissue, but the opposite is the case. The assertion which has been made that they develop better in the sputum than in the pulmonary parenchyma is, to say the least, very doubtful.—*Journal de Médicine de Paris*, November 1, 1885.

The Action of Nitroglycerine in Nephritis.—Dr. Burginski formulates the following conclusions from a series of investigations which he has made concerning the treatment especially of parenchymatous nephritis (*Brach*, No. 21, 1885). 1. Nitroglycerine in small doses reduces the amount of albumin in the urine. 2. It increases the total quantity of urine excreted, and this effect is observed for some time after the administration of the drug has been discontinued. 3. The amount of albumin is still further reduced when the drug is given in gradually increasing doses. 4. Nitroglycerine appears to have no influence upon the specific gravity of the urine, nor upon the weight of the individual. 5. The only unpleasant effect of the drug, when given in Bright's disease, is a slight and transitory headache, observed sometimes at the commencement of treatment.

Chicken-pox and Small-pox.—M. d'Heilly, of Paris, during an epidemic in his wards of chicken-pox, made several inoculations, which succeeded three times in ten. Trousseau attempted, but was always unsuccessful; Steiner succeeded in eighty per cent. After successful inoculations, chicken-pox is not preceded by prodromata. The period of incubation is from three to seventeen days, an average of from fourteen to seventeen. Chicken-pox always resulted, and never small-pox. One of the children had been previously attacked by small-pox; the subsequent attack of chicken-pox ran its usual course. In children previously vaccinated and then inoculated with small-pox, the vaccination-pustule dried on the eighth day; chicken-pox appeared on the twelfth, and followed its ordinary evolutions. In one case, a small-pox eruption appeared two days after the chicken-pox eruption, and went on through all the stages. M. d'Heilly considers that these facts demonstrate that chicken-pox and small-pox are two distinct diseases. The period of incubation can be co-existent or follow closely one after the other. Chicken-pox vaccination did not leave any marks, and the eruption was not near the area of vaccination. M. d'Heilly vaccinated from chicken-pox vesicles on the second day. M. Dumontpallier observed that M. d'Heilly's experiments were not conclusive, because the children vaccinated for small-pox remained in the ward among the children suffering from this disease. The experiments of the same kind he had made with Trousseau all failed, the children were removed from contact with chicken-pox patients.—*Brit. Med. Journal.*

Not a "Complication of Diseases."—Medical Examiner: What did your father die of? Applicant: Oh, just *plain* death.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 12, 1885.

THE FINAL REPORT ON THE CHOLERA BACILLUS.

THE full text of the report made by Drs. E. Klein and Heneage Gibbs, on the subject of the relations of the comma-bacillus of Koch to cholera, has been published. With it is a report of a Committee appointed by the Secretary of State for India to pass upon the report of the Cholera Commission. This Committee was composed of Dr. Burdon-Sanderson, Sir J. Fayrer, Sir William Gull, Sir W. Guy Hunter, Sir W. Jenner, Dr. Timothy Lewis, and several others.

The full report of the Commission contains in effect no new facts, but only a more elaborate discussion of results of the investigations of Klein and Gibbs. These gentlemen reiterate their statements: 1. That the comma-bacilli, though occurring ordinarily in cholera, do also occur in other diseases. 2. That these bacilli do not always occur (as claimed by Koch) in vast numbers in the intestine, and that they are not always found in the intestinal tissue, but only in the mucous flakes. 3. That the comma-bacilli, when cultivated and injected into the system of lower animals, do not produce genuine Asiatic cholera; and, finally, that the comma-bacilli were not always found in water-tanks in the vicinity of places infected with cholera, while they were found in some tanks in neighborhoods not infected.

The conclusions of the Committee are summed up as follows:

"1. Comma-shaped organisms are ordinarily present in the dejections of persons suffering from cholera, but not in the blood, the intestinal mucous membrane, or any other tissue. 2. Comma-shaped organisms of closely allied morphological appearances are ordinarily present in different parts of the alimentary canal in health, and are developed to an unusual extent in certain diseases in which there is copious intestinal secretion; the predominant form in any given case depending in a great measure on the nature of such secretion. 3. The comma-shaped bacilli ordinarily found in cholera do not induce that disease in the lower animals, and there are no real grounds for assuming that they do so in man. 4. The committee expressed its 'conviction that sanitary measures in their true sense, and sanitary measures alone, are the only trustworthy means to prevent outbreaks of the disease, and to restrain its spread and mitigate its severity when it is prevalent.'"

The conclusion of the whole matter is that the causal relation of Koch's comma-bacillus to Asiatic cholera is "not proven."

Of the scientific value of the English Commission's report we have already expressed an opinion. While exhibiting much technical skill and labor it was not a thorough piece of work, and showed both a bias against Koch, and a lack of appreciation of some of the most essential points made by Koch. Though the report has been "tinkered" considerably since its substance was first communicated there is no reason to change the above expressed opinion of it.

As for the conclusions of the Committee they are utterly inane and valueless. A number of the members were gentlemen already committed irrevocably to special views of cholera, while others were gentlemen distinguished mainly as general consultants, and having not the slightest expert knowledge of bacteriology.

Since Klein and Gibbs made their investigations several most careful experimenters have corroborated Koch by studies much more exhaustive and exact. While the comma-bacillus may yet be regarded as of doubtful specific character, its claims for such character are much stronger than would be supposed from the conclusions of the English Commission and the English Committee.

THE PRACTICAL WORKING OF LAWS REGULATING MEDICAL PRACTICE IN THE UNITED STATES.

UNDER the above title Dr. Richard J. Dunglison makes a report to the American Academy of Medicine of the results of an inquiry into the working of the various medical laws in the United States.

The report is valuable as giving the opinions of prominent physicians who reside in the different States, and who have some direct and personal knowledge of the question at issue. It has to be confessed that a perusal of Dr. Dunglison's paper does not leave one in a particularly encouraged state of mind. It is true that nearly all the correspondents write hopefully, and nearly all believe that in time some medical legislation will be accomplished which will benefit both the public and the profession. The main complaint everywhere is, that it is difficult to obtain a law, and still more difficult to execute it, because the people or their legislators believe that it is "class legislation," and intended for the benefit of the doctor.

A few of Dr. Dunglison's correspondents express the view that all attempts at regulating medical education and practice by law are unwise and not in harmony with the spirit of our institutions. The matter has been often argued, and we do not propose to revive it again now. We believe that the opinion of most of those who have thought seriously upon the matter is in favor of some form of State regulation of medical practice. Unlike the clergyman, or lawyer, the doctor is, in his professional capacity, an officer of the State. He renders his services to it in his reports of deaths, births, and contagious diseases, and as a medical witness in courts. The State has a right, therefore, to see that its officers are competent. Beyond all this, the physician who is uneducated and incompetent is a source of danger to the public health, and here again the State has a right to protect itself.

With the greater maturity of our country we believe that public sentiment will sustain efficient laws to these ends. Nor does it seem possible that it can take a very long time for the public to learn and admit that a community supplied with well-trained medical men will be in a safer and healthier condition than if supplied simply on the supply and demand principle.

THE BLOT UPON THE BRAIN.[1]

Psychological studies are among the most fascinating in literature. There is implanted within the human breast a liking for oddities, and when these concern that most mysterious of human organs, the brain, there comes to each individual who reads a sort of personal appeal unlike anything else in *belles-lettres* or scientific writing. The possibility of your gray cells or your neighbor's gray cells escaping their task-master, and performing freaks which, since they occur in others, is manifestly inherent within them, adds a curiosity half pleasurable, half painful, a piquant mingling which one would not forego.

Dr. Ireland has brought together a baker's dozen of such papers, under the sensational title of "The Blot upon the Brain." In his book he makes a bid for a wider circle of readers than those interested in medical psychology alone. To prepare these, he presents in his opening paper, on "Hallucinations especially of Sight and Hearing," a cursory glance at the nervous system; at the same time he desires to place all his readers in a proper frame of mind to receive his historical sketches, which follow. These form the most interesting and entertaining portions of his book. Exceedingly well written and carefully worked up, they focus an intellectual light upon the individuals who for many centuries have been, because of their strange and unaccountable acts, colossal statues in history, which have dwarfed all others and have made their names adjectives, by which is condensed in one word their distinguishing peculiarities. Among such are Joan of Arc, Mohammed, Nero, and others of royal blood.

The author justly remarks: "In psychology speculation has long done its best, and it is to observation that we must look for more light; but let us not run away with the notion that we understand the nature of hallucinations when we have indicated their anatomical seat. There is a mystery about the relations of sensation and perception of nerve tissues which cannot be explained."

With this idea paramount, the writer turns his attention to the historical personages just spoken of. The hallucinations of Mohammed, Luther, and Swedenborg are considered, which are familiar to readers of history; but the interest in these papers and those following resides in the fact that the author has brought them together and shown their relation to concurrent events. For delicacy of handling, and nicety of portrayal, the paper on "The Character and Hallucinations of Joan of Arc" takes the precedence. The portraiture of the inspired peasant girl, drawn in its psychological aspect, is so finely done that it is like some picture painted by an artist who has had a fresh inspiration with reference to an oft-considered subject, which far removes his creation from the every-day hackneyed conception.

The third historical study is entitled "The Insanity of Power." With this may be included "The History of the Hereditary Neurosis of the Royal Family of Spain." In all of these is shown the descent, from one generation to another, of the functional nervous disturbance which appeared as epilepsy in some, as flagrant insanity in others, giving to the world such monsters of iniquity as Nero and Caligula, of Rome; Mohammed Toghlak, the Sultan of India, whose cruelties are too horrible to be mentioned; the atrocities of Ivan the Terrible and his descendants. About the throne of Spain, for three hundred and fifty years, lurked an hereditary neurosis, which, to quote our author, "passing over a generation, and appearing in various forms and intensities as epilepsy, hypochondria, melancholia, mania, and imbecility, at length extinguished the direct royal line of Spain. The baneful tendency in the blood was re-enforced by close intermarriages with families of the same stock." In concluding his paper, the writer answers the question, "Who is well born?" and, in answering, points the moral of his tale:

"Whoever attends closely to history must know that there is a great deal in birth, but not birth as fixed by laws and traced by heralds. A man who is well made, strong, mentally gifted, and able to do much work and stand much strain must be well born; and a race sodden with epilepsy, insanity, and scrofula, whatever its fictitious rank, is necessarily low born, and in reality not worth preserving. The royal families of Europe have shown a tendency to segregate themselves, as if the possession of political power conferred some peculiar virtues on the stock, and this leads them to seek alliances which sound notions would teach them to avoid, and to brand as morganatic, or left-handed, marriages which would purify the blood. If the people they rule over had any voice in such matters, as they have so deep an interest, they would forbid two royal families, each tainted with insanity, from intermarrying with one another, as fraught with great dangers, not only to the family, but to the nation placed under its rule, and which must suffer for the extravagance of its members."

The concluding papers, "Fixed Ideas," "*Folie à Deux*," "Unconscious Cerebration," "Relation of Words to Thought," "Left-Handedness," "Mirror Writing," and "The Dual Functions of the Brain," are often very suggestive and interesting; at other times there is superficiality in the treatment and a lack of breadth in striking contrast to what one is led to expect from the consideration of some of the other subjects.

Space does not now permit us to enter into a detailed exposition of these statements, nor can we dwell longer on much that is worthy of the attention.

A marked detraction from the scientific aspect of the book are the sensational headings of the pages, drawn from some incident related. To illustrate, one page is entitled "Is She Pretty, or Not?" another, "Suspicious of Shrewd People;" still another, "Our Idea of a Solid Body," etc. When he considers some of the deep problems of psycho-philosophy his style is somewhat rambling and ambiguous, and the reader trying to follow the argument is further distracted by these captions which head the page, which, if not as sensational as those quoted,

[1] The Blot upon the Brain: Studies in History and Psychology. By William W. Ireland, M.D., Edinburgh. Published by G. P. Putnam's Sons. New York: 1886.

are often wide of the mark. These defects, however, are pardonable, since in the main the book is readable, entertaining, and instructive far beyond the average.

ALLEGED HYDROPHOBIA AND ITS ALLEGED METHOD OF PREVENTION.

The history of hydrophobia in Newark, N. J., during the past two weeks, is full of dramatic and scientific interest. An alleged mad dog ran through the streets of the city and bit a large number of other dogs, as well as six previously healthy children. The quantitative development of the hydrophobic virus (and this furnishes the first point of interest) was certainly very large, for, besides six children and six dogs known to have been bitten, a number of other dogs were believed to have suffered, and were in consequence promptly shot by the intelligent police. The spinal cord of the original alleged mad dog has been preserved for experiment, the six bitten dogs have been corralled by the Board of Health for the purpose of observation, and four of the bitten children have been sent to Paris for purposes of "Pasteurization."

At date of writing it is still uncertain whether the dog was mad, and it is rather more than certain that Pasteur's preventive inoculations are of no value whatever, except to relieve mental distress. Therefore, we are as yet unable to say whether the hydrophobia fright in Newark is to turn out a comedy or tragedy.

It is gratifying, however, to see the ready sympathy so practically displayed toward the bitten children, and the prompt appreciation by our community of the possibilities of a novel preventive measure.

WISHING TO BE LET ALONE.

By an extraordinary process of reasoning, the *Journal of the American Medical Association* attempts to show that there is now no longer any reason for criticism, protest, or discussion regarding the management of the International Medical Congress. Having turned a masterly somersault in defending as parliamentary a procedure that it at one time was at extraordinary pains to condemn, it now believes that every one should cease complaining, and let its affronts and inconsistencies alone. We are strikingly reminded of a once popular poem concerning an "old cove" who sat at an advantageous spot and shied stones at the passers-by. He, too, only wished "to be let alone."

It is, however, not reasonable to expect that a policy which excludes so many leading men from all honorable connection with the Congress, shall not continue to be criticised.

OCCUPATION AND MORTALITY.

In an introduction to the supplement to the Forty-fifth Annual Report of the Registrar-General, Dr. William Ogle has given some instructive facts regarding the mortality-rate of different occupations. His figures are based on the British census for 1881 and the recorded deaths in the Registrar-General's office for the years 1880, 1881, and 1882. They cover only deaths occurring in males above the age of fifteen (of whom there are 8,000,000 in England and Wales) and indicate the comparative mortality-rate in seventy-three different industries.

Dr. Ogle shows, first of all, that the mortality-rate for persons between the ages of twenty-five and forty-five has decreased, while that for persons between forty-five and sixty-five has increased.

In order to indicate the comparative mortality of different occupations, he takes as an average mortality figure for all males in England, 1,000. He then finds that to every 1,000 deaths among male adults of all classes, there are only 556 among clergymen and priests. Next to this class, in healthfulness, come the gardener and nurseryman with 599 deaths, the farmer and grazier with 631, and the farm laborer with 701

The figures for the other occupations, or groups of occupations, increase rapidly, and at the bottom of the list appear the following: Plumber, painter, and glazier, 1,202; cutler and scissors-maker, 1,309; musician and music-master, 1,314; hairdresser, 1,327; cab and omnibus service, 1,482; chimney-sweep, 1,519; innkeeper and publican, and wine and spirit dealer, 1,521; messenger, porter, and watchman, 1,565; file-maker, 1,667; earthenware manufacturer, 1,742; Cornish miner, 1,839; costermonger, hawker, and street-seller, 1,879; general laborer in London, 2,020; and inn and hotel servants, 2,205. Compared with the clerical, the legal and medical professions appear in a far less favorable light: the mortality figures for barristers and solicitors is 842, and for physicians, surgeons, and general practitioners, so high as 1,122, against 556 only in the clerical profession.

It thus appears that in England two doctors die for every clergyman.

Some light is thrown upon the causes of the excessive death-rate in some occupations. Thus among inn-keepers and saloon-keepers, who have the high comparative figure, 1,521, the deaths from alcoholism and liver-disease are five times greater than the average among males. Among file-makers, plumbers, and painters there is an excessive death-rate from diseases of the urinary system. The mortality-rate for phthisis is very low among farmers, fishermen, and gardeners, while it is very high among file-makers, printers, earthenware manufacturers, and is highest of all among Cornish miners. On the other hand, it is very low among coal-miners.

Dr. Ogle's statistics are interesting, but they are vitiated in a measure, as he himself, we believe, admits, by the fact that it is not alone occupation, but the home and domestic environment that have to do with mortality. In this country, also, the element of climate would have to be considered.

THE HEALTHFULNESS OF HEATED STREET-CARS.

Considerable discussion has been going on as to whether it is better, from a hygienic point of view, to have street-cars heated. It requires but little observation to see that, as some cars are heated, it is undoubtedly unhealthful and unsafe. Ill-tended fires in hot and dirty stoves simply develop smells, intensify contagion, and render travelling unsafe by reason of the sudden changes from pure cool air to that which is hot and foul. It is, we believe, conceded that the conductors on these cars

suffer more frequently from colds and bronchial disorders than those on the unheated cars.

It is perfectly safe, however, and much more comfortable to have cars moderately heated, provided they are also kept clean, and, provided also, that some attention is paid to ventilation, so that the car is not an almost air-tight box, except when the doors are opened.

SNEAK-THIEVES AND DOCTORS' OFFICES.

It is quite time that our police authorities showed some capacity for dealing with sneak-thieves. In this city the class in question have been making constant depredations upon doctors especially, until matters have reached such a pitch that it is more than simply a question of overcoats and mantel-clocks that is involved. We are hardly aware of a single physician in this city who has not had some disagreeable experience with sneak-thieves, and the result now is that many medical men refuse to go to any new address when summoned professionally by strangers. Over and over again we hear the story of a man calling and saying that medical help is needed at a certain address. If the doctor is out, "he thinks he will wait;" and if the servant is unwary, he absconds with whatever he can lay his hands upon.

The results of all this, as we have said, are now reaching beyond those of petty loss of personal property. It is sometimes difficult for a sick man to get a reputable physician in an emergency. His own medical attendant may be away, and another is hurriedly summoned; but, warned by experience, the doctor refuses to go without some assurance of good faith.

We can readily understand that serious harm may happen through this state of affairs.

When physicians call upon the police for protection, some stupid political detective saunters around and listens politely to the story. He thinks it over, and that ends it. Can we not have something more done than this?

THE PRESENT ASPECT OF THE TREATMENT OF TYPHOID FEVER.

In *Schmidt's Jahrbücher* for October last Dr. Arthur Geissler reviews the contributions to the literature of typhoid fever made in the past three years. In the direction of therapeutics these contributions have been quite numerous. A study of them shows in a striking manner the two main tendencies in which efforts to find helps in the treatment of typhoid have been directed, viz., toward antipyretics and antizymotics. On the one hand is a numerous school which advocates the use of cold baths, or of quinine, salicin, antipyrin, and its allies; on the other, an almost equally large constituency which commends carbolic acid, or carbolic acid and iodine, calomel, naphthaline, and similar drugs. It is difficult to say as yet which has the preponderance of support.

It is certain, however, that the cold-water treatment has received a decided set-back both in Germany and in France. The discussions which took place in 1883–84 at the Académie de Médécine on typhoid fever, elicited opinions which, on the whole, were decidedly unfavorable to the systematic use of hydrotherapy. A recent discussion at the Berlin Medical Society, in which Senator introduced the subject of the treatment of typhoid fever, brought out also a large amount of evidence against the systematic use of this measure. Very significant are the statistics of Dr. Gläsel who, in two divisions of the Hamburg hospital, treated one set of patients with antipyresis, the other with antizymotics. In both wards there was a mortality of about seven per cent.

Of antipyretic drugs, quinine still holds a firm place. Herard, Gee, and Jaccoud are among those who still express their preference for it. On the other hand, Unverricht, Legouest, Blot, Hardy, and Dujardin-Beaumetz either dislike its effects or prefer some other antipyretic. Desplats, Dujardin-Beaumetz, and Vulpian decidedly favor the use of salicylic acid, or one of the salicylates; but Dr. James Fergusson has expressed the opinion that they increase the tendency to intestinal hemorrhage. As regards the pure antithermics, such as antipyrin and thallin, Professor Jaccoud has recently asserted, in a paper read before the Académie de Médécine, that they have absolutely no effect upon the course of the febrile disease, and are no real acquisitions to therapeutics. In this opinion he is beginning to find many supporters.

The use of disinfectants or germicides in typhoid fever is not a new one, but it has of late had some very enthusiastic advocates.

Among these are Remonet, who began the treatment in 1880, and who advocates the use of large doses of phenol (gr. xv., once to thrice daily given in enemata). Other believers in this drug are Dr. Amet, Professor Cantani, who claims that it will abort the fever in many cases, and Pécholier. On the other hand, many prominent therapeutists have expressed themselves decidedly against it, and certainly the use of large doses has not gained any foothold with the profession. The administration of carbolic acid and iodine in moderate doses, however, has numerous advocates in Germany and elsewhere. The formula of Rothe, which was published in The Medical Record a few years ago, has become popular. In this country, Drs. Bartholow and James Wilson recommend the use of the two drugs, and Geissler mentions reports in its favor by Klammann, Raymond, Kurz, and Sansom.

The latest addition to drugs of this class is naphthaline, which has been reintroduced into therapeutics by Professor Rossbach. This cautious observer believes that it will have the effect of shortening or even aborting attacks of typhoid fever in some cases. Dr. Götze, of Jena, gives some facts in corroboration of such a view.

One cannot but be struck with the large amount of evidence that has gradually been collected in favor of such germicidal drugs as phenol, phenol and iodine, naphthaline, and perhaps we might put in this category salicylic acid and calomel. For three of them, viz., salicylic acid, phenol, and naphthaline, effects abortive to the fever have been claimed. It is safe to conclude, at any rate, that only agents of this disinfectant class affect the course of typhoid, and that all forms of antipyretics seem only to lessen the severity of the symptoms. From the present evidence it would appear that fresh air, careful employment of nourishment and stimulants, the rational occasional use of antipyresis, and the *systematic* use of some disinfectant constitute the best treatment now known for typhoid fever.

THE LADIES' TIPPLE.

That popular abomination known as "Beef, Iron, and Wine," which is now sold so extensively, not only by druggists, but by tradesmen of various kinds, deserves a little special attention from the medical profession. It is an agreeable mixture to the sight and taste; its name is a triple combination of seductive mononyms; while, taken into the stomach, it acts as a gentle "pick-up" to the worn and over-sensitive nerves of the ladies. It has in consequence become a popular, if not a fashionable, tipple, and is indiscriminately used to an extent that is, we believe, not entirely free from danger. Every medical man knows that the amount of actual beef or food in these various preparations is insignificant, and that it is the wine, after all, that makes them liked, and that leads so many persons to purchase their second bottle.

There is no good reason why this mixture is allowed to be sold by those unlicensed to sell wines, and if the law supports the practice it is the duty of physicians at least to try and lessen it. Inebriety can result from these tipples.

A STORY WITH A MORAL.

The wicked do not always prosper, and it is not always safe to visit a patient whom you have never seen before, and criticise the treatment of the family physician. The following tale, which we find related in the *Journal de Médecine de Paris*, is illustrative of this fact.

A young cavalry officer had sustained a severe compound comminuted fracture of the leg some years ago, and although he was able to attend to his duties, suffered at times from the passage of little spiculæ of bone from the wound. One evening he was taken with fever and sore throat, and Dr. Danet, the family physician, saw him and prescribed for an acute pharyngitis. The following day the patient felt well, but in the evening had a fresh attack of fever, the pain, however, being at the seat of the old fracture and not in the throat. The part was red and hot, and the patient complained bitterly of the pain. A surgeon was now called, without the knowledge of the family physician, and gave as his opinion that the trouble was due to the presence of a loose splinter of bone, and ordered poultices. Dr. Danet was now summoned, and knowing the patient well, and being aware that he was of a rheumatic diathesis, was reserved in his diagnosis, and prescribed anti-rheumatic remedies.

As the man did not recover at once, the family became somewhat anxious, and called a well-known professor, who saw the patient in the absence of Dr. Danet. He said at once that there was nothing to do but to cut down and resect a portion of the tibia. The family physician called, as usual, soon after, and was not pleased when he heard of what had happened. He removed the poultices, told the patient to continue his quinine and salicylate, and assured him that the trouble was rheumatic. In two days the young officer mounted his saddle as well as ever.

Moral: Don't be unkind to the general practitioner.

The Physicians of Philadelphia number 2,500. New York has about 2,900.

News of the Week.

The Club System of Medical Attendance in Berlin.—The statement is made in an exchange that a club of 4,800 members, in Berlin, recently advertised for six medical officers to attend them at a salary of $375 per annum each. This would make the contribution from each member of the club about seventy-five cents a year for medical attendance. More than four hundred doctors applied for the places.

The Late Dr. Carpenter died by accident in connection with the use of a hot-air bath at home. The safety-lamp of his bath being out of order, he extemporized a lamp with common spirit in a gallipot.

One of Pasteur's Patients Dies.—A cablegram of the 6th inst., from Paris, says: A girl who was bitten by a mad dog, and subsequently inoculated by Dr. Pasteur, has died of rabies. Dr. Pasteur explains that thirty-six days having elapsed before she was inoculated, the period of incubation had expired, and the treatment was therefore too late.

Hydrophobic Inoculation.—The daily papers telegraph the criticisms upon Pasteur's preventive inoculations for rabies made by female writers of fiction, like Ouida, and female writers of anti-vivisection nonsense, like Dr. Anna Kingsbury, whoever she may be. All the points, and more, made by these critics were made with scientific precision by Dr. Jules Guérin at the time Pasteur first announced his discovery; and they have also been made in the columns of The Record. The Associated Press bows somewhat too profoundly to lovely woman.

The Late William H. Vanderbilt.—The medical profession will remember with gratitude that the late Mr. Vanderbilt's largest known gift, half a million of dollars, was to a medical institution—the New York College of Physicians and Surgeons.

The New Crematory near this city was first used last week for the incineration of a human body. It did not work perfectly, but it is expected to do so.

Intubation of the Larynx in Membranous Croup.—Dr. F. E. Waxham, of Chicago, reports six cases of croup in which intubation of the larynx was practised according to the method suggested by Dr. O'Dwyer. Two of the patients recovered.

Medical and Surgical History of the War.—The manuscript of the third medical volume of the "Medical and Surgical History of the War," and the last of the series, is now well advanced toward completion; its earlier chapters are in the hands of the printer. The work will probably be ready for issue during the coming winter.

The Cleveland Medical Gazette is the title of a new medical monthly edited by Drs. A. R. Baker and S. W. Kelley, and published in Cleveland, O. There are, we are told, four hundred physicians in Cleveland, and the *Gazette* intends to be a "live local journal."

The next Series of Cartwright Lectures will be delivered by Dr. William Osler, of Philadelphia. So far no practising New York physician has delivered this course.

The U. S. Army Medical Library now contains 72,219 bound volumes and 95,923 theses and pamphlets.

The First Session of the American Public Health Association.—The American Public Health Association met in its Thirteenth Annual Convention in Washington, D. C., December 8, 1885, with Dr. James E. Reeves, of Wheeling, W. Va., President of the Association, in the chair. When the Convention had been called to order by the President, Dr. Townshend stated briefly the arrangement made by the local committee for the meeting and for the entertainment of members. About one hundred and twenty-five new members were then elected. The first paper read was on "Sanitary and Statistical Nomenclature," by Dr. E. M. Hunt, Secretary of the State Board of Health, Trenton, N. J. It contained suggestions as to restrictions to be placed upon the meaning of various terms used in sanitary reports. The next paper presented was by Dr. J. S. Billings, U.S.A., in which he suggested changes and improvements in, forms of tables for vital statistics. Dr. Henry B. Baker, Secretary of the State Board of Health of Lansing Mich., read a paper on "The Relations of Rainfall and Water-supply to Cholera." Dr. Baker's paper was illustrated by several statistical tables and diagrams based upon the statistics of cholera in Calcutta from 1865 to 1884, inclusive, and the meteorological reports for the same period. These tables showed that cholera and rainfall bore a statistical relation, the mortality being greater in seasons of little rain and *vice versa*. The tables showed also that the mortality was greatly reduced upon the introduction in late years of a good water-supply. Dr. D. E. Salmon then read a paper on "The Virus of Hog Cholera," in which were given in detail the experiments made by the Bureau of Animal Industry. The Hon. Erastus Brooks, of New York, said this was a commercial as well as a sanitary question. He referred to the action of the French and German authorities in prohibiting the importation of American pork. He heartily urged that the subject should be further discussed. Dr. T. S. Verdi, of Washington, a homœopath, said the assumption that our animals arrived in Europe in a diseased condition was only an excuse to keep out the American cattle. Mr. Brooks said that while this was probably true, it was not the whole truth. The alleged improper packing of pork, rendering it unfit for use when it arrived in France, was the avowed cause of the prohibition in France. He referred to the tariff duties imposed here as tending naturally to retaliatory measures. He thought it was our duty to see that food sent abroad was properly packed. Dr. Reed, of New York, offered a resolution recommending legislation, national, State, and municipal, to provide protection for the people against the sale of diseased meat.

The Question of Quackery in England.—We read in the *Medical Press and Circular* the following from a correspondent of that journal: "Sir—I am not aware of any subject of such vital importance to qualified and registered practitioners as the large and ever-increasing number of quacks in the United Kingdom, but particularly in England." Yet we are told by an Anglo-Californian that quackery is almost unknown in England, and that the *Medical Register* settles the status of every one at once. Concerning this, the correspondent adds later: "Few lay persons, of whatever social position, are aware of the existence of that legal publication, the *Medical Register*, nor does the General Council apparently care whether they are or not."

A Collective Investigation of Yellow Fever in Peru has been set on foot by the Lima Academy of Medicine.

Death in a Dentist's Chair from Nitrous Oxide.—A French dentist, named Duchesne, has got into serious trouble owing to the death of a patient while under the influence of laughing-gas.

Lady Medicals and the Drama.—The Parisians, says the *Hospital Gazette*, have been enjoying a good laugh lately at the expense of the ladies, or rather at the medical portion of the gentler sex. The occasion for the mirth is a most humorous comedy which has been produced recently at the Gymnase Theatre, entitled, "The Female Doctor," and which deals with this modern excrescence of social life in a most amusing and ridiculous manner.

A New Hypnotic.—M. Dujardin-Beaumetz having tried it in only nine cases comes forward with the announcement that phenyl-methyl-acetone is an excellent hypnotic, and in alcoholism superior to chloral. It is given in doses of five to fifteen centigrammes.

The Cause of the Poison of the Cholera Bacilli.—MM. Nicati and Rietsch have discovered toxic ptomaines to result from the growth and activity of the cholera bacilla when cultivated in broths and peptones. These toxic products when injected into mice killed them. Nicati and Rietsch support Koch in his views of the specific character of these bacilli.

About the Truth of It.—Client (to Lawyer)—I am afraid the physician's testimony will convict me. Lawyer (reassuringly)—Don't be alarmed about that. I'll read up a little about poison in the stomach, and in ten minutes I'll have that doctor in a cold sweat, and make the judge and jury think he is a hired perjurer.—*New York Sun.*

A Much-bitten Anti-vivisectionist.—The lady secretary of the Anti-vivisection League of England argues, in a letter to M. Pasteur, that cauterization removes all danger of hydrophobia. Her son once, and she herself five or six times, have thus escaped the malady, and both offer to be bitten by any mad animal in M. Pasteur's laboratory on condition of being allowed to treat the wounds themselves.

The Amenities of the Profession in Texas.—This professional item appears in the Texas *Courier-Record of Medicine:* "Dr. Palmer, who, in a fight with Dr. Calloway at Blooming Grove, had the end of his finger bitten off by the latter, is in a critical condition owing to blood-poisoning having set in. The finger was amputated, but it is thought this will not save his life."

Defence of an Anti-vaccinator.—Dr. M. M. Mitivier, of Montreal, sends us a long communication defending the character and scientific attainments of Dr. Emery Coderre, who has acquired some notoriety in the anti-vaccination cause. Our correspondent informs us

that Professor Coderre is a gentleman of profound and extensive knowledge, and of an admirable personal character. All of which we are pleased to learn and record. None the less can we doubt that he has not a judicious mind, and that, if reports are true, he has been a source of discord and mischief in Montreal.

Protests from Anti-vaccinationists.—We have received several communications from indignant anti-vaccinationists protesting against our position in assuming that the utility of vaccination is established and need not now be discussed. One esteemed correspondent writes: "I am a reader and a hearty admirer of The Record, but I must say if there is anything contemptible and high-handed treason in this world, it is the way in which you treat the subject of vaccination. You 'hold the fort' to suit yourself, at the head of a popular journal, and do not allow both sides to be fairly presented." To this we can only say that, to all persons who are capable of weighing evidence the utility of vaccination is perfectly demonstrated, and it is a waste of time and space to open our columns to its discussion.

A German View of the International Medical Congress.—The German medical profession is much exercised about the International Medical Congress to be held in 1887 in America. The original Central Committee had for its president Professor Austin Flint, and for its secretary Dr. Billings, and numbered the best-known names in America. Unfortunately, the difference between the Old Code and the New Code of medical ethics have made themselves felt anew. The chief difference lies in the relationship of the profession to homœopaths and irregular practitioners. Besides, a desire was expressed to have separate representatives of each State—a geographical representation. Thus, although the original Committee was nominated by the American Medical Association, a new Committee has been formed, with Dr. Shoemaker at its head. Every one of importance on the older Committee has declined to belong to the new one. Germany has been appealed to to support the old Committee, which it does unhesitatingly. The *Berliner Klinische Wochenschrift*, No. 43, pleads that there is yet time to mend matters, for the American Medical Association meets again next spring.—*Brit. Med. Journal.*

A Country with Few Doctors.—The number of legally qualified practitioners in Finland is, at the present time, 187. From 1640 to 1750 there was only one legally qualified man, a medical professor at Abo (without counting naturalized military surgeons). In 1750 the number increased to three or four, but at the close of the last century there were about twenty practitioners.

Cocaine in Sea-sickness.—A good deal of evidence is coming in as to the value of cocaine in sea-sickness. It is given in doses of gr. ¼ to gr. ¾ in solution, or in capsules.

Virchow on Specialties.—In his recent address at the anniversary of the Berlin Medical Society, Professor Virchow said: "Since that time [twenty-five years ago], the great host of specialties has developed in Germany, and it would be in vain, anyhow fruitless, to oppose this tendency; but I think I ought to mention it here, and hope I shall be certain of the approval of all of those present, when I say that no specialty can flourish which separates itself entirely from the common source of science; that no specialty can develop fruitfully and beneficially, if it do not ever and anon draw from the common fountain, if it do not take the other specialties into account, and if all the specialties do not mutually assist one another; thereby, a fact which is perhaps not always considered necessary for practice, receiving knowledge through that unity on which our position internally, and I can also say externally, rests. For, gentlemen, it would be the most foolish and most dangerous development, if the system of specialties should ever come to such a pitch that special schools were founded in which special branches were taught without any knowledge of other things offered us by the science of medicine."

The International Medical Congress of 1887.—A meeting of members of the medical profession interested in the International Medical Congress in 1887, to which prominent medical men from a number of cities were invited, was held at the Hall of the College of Physicians, Philadelphia, December 4, 1885, Dr. D. Hayes Agnew in the Chair. It was stated that official notice had been given of the election, as members of the present Executive Committee of the Congress, of Drs. J. S. Billings and J. M. Browne, of Washington, D. C.; Christopher Johnston, of Baltimore; George J. Englemann, of St. Louis; and J. M. Da Costa and William Pepper, of Philadelphia. Sincere regret was expressed that hasty action on the part of the Association, and the introduction of false issues, had imperilled the success of the Congress. It was made entirely evident, however, that the acceptances of the above elections would not be regarded as affording any adequate guarantee for the future scientific conduct of the Congress, and consequently would not be followed by any co-operation on the part of the leading members of the profession now unwilling to join in that work. As to the reorganization of the Congress, it was the sense of the meeting, unanimously expressed, that if the present Executive Committee should unite with them the Original Enlarged General Committee, and recommence the organization *de novo*, this course would insure the desired result. This is little better than a forlorn hope.

The Use of Carbonate of Ammonia in Cerebral Hemorrhage, Embolism, and Thrombosis.—Dr. R. C. Van Wyck, of Hopewell Junction, N. Y., writes: "In your journal of Nov. 21, page 568, on the 'Use of Carbonate of Ammonia in Cerebral Hemorrhage, Thrombosis, and Embolism,' the dose used by me is given as five grs. in ʒ ss. (half drachm) of solution liquor ammoniæ acetatis; it should be ℥ ss. (half an ounce) of liquor ammoniæ acetatis. In passing, permit me to say that since this article has appeared in *Gaillard's Medical Monthly*, I have treated successively two other cases in persons of advanced years, both females, aged eighty-two and ninety-three years respectively. Both of these cases are now able to dress themselves and go up and down stairs and around the house by the aid of canes—the older, using two canes, is quite lame; the younger one using only one, and then sometimes omits that. She has been to her son's house visiting, a distance of three miles over very rough mountain roads."

Reviews and Notices.

Transactions of the Medical Society of the State of New York for the Year 1885. 4to, pp. 400.

The usual arrangement of matter is followed in this volume. Of particular interest to New York City physicians are the memorial addresses on the late Drs. Willard Parker, James R. Wood, John Glover Adams, and Joel Foster. Among the papers published there is the usual variety of subjects. Dr. Vanderveer's paper on "Personal Observations on the Work of Mr. Lawson Tait," is very interesting reading. The discussion which followed this paper showed that many of the Society members were not ready to follow Mr. Tait in discarding antiseptics altogether, and relying on mere surgical cleanliness. Dr. Howe's paper on the "Effect of Cocaine upon the Healing of Wounds" states at its conclusion, that "in lesions of the conjunctiva perfect solutions of hydrochlorate of cocaine have no appreciable effect, beneficial or otherwise, in the healing process." In corneal lesions it is an inferior mydriatic to atropine. Its inferiority in wounds of the iris is also noticeable. The volume closes with a copy of the Laws of the State of interest to the medical profession enacted by the Legislature of 1885.

Manual of the Diseases of Women. Being a Concise and Systematic Exposition of the Theory and Practice of Gynecology. By Charles H. May, M.D. Pp. 349. Philadelphia: Lea Brothers & Co. 1885.

To judge from the number of condensations of the various branches pursued in medicine, the demand for this kind of literature, that is, "the concise and systematic," is very great. The present volume, viewed in the light in which it presents itself for consideration, is successful, and will commend itself to students cramming for examination, or preparing for quiz classes.

That it will win for itself a place among practitioners can scarcely be hoped, since the questions that arise among them are generally such as are not answered in text-books, or those volumes which take only a cursory view of the subject.

Diabetes Mellitus: A Synopsis of its Pathology, Physiology, Etiology, Incipient and Progressive Symptoms, Causes of Death, Sugar Tests, and Treatment. By Harvey J. Philpot. Pp. 112. London: Sampson Low, Marston, Searle & Rivington. 1884.

The title explains the contents of the monograph under consideration. It adds little that is new to the subject of which it treats. A careful perusal of its pages leads the reviewer to question why the author, who states that he does "not pretend to propound new theories of his own, nor herald any infallible remedy for this perplexing and harassing disease," ventures upon a work which has been so well done in the many books of general medicine.

Clinical Therapeutics — Lectures in Practical Medicine. Delivered in the Hospital St. Antoine, Paris, France, by Professor Dujardin-Beaumetz. Translated by E. P. Hurd, M.D. Pp. 491. Detroit, Mich.: George S. Davis. 1885.

This volume includes the clinical therapeutics of nervous diseases, of general diseases, and of fevers. It is introduced by an author's preface, in which he alludes with satisfaction to the success of the work, it having already run through four editions in France, and been successively translated into Spanish, Italian, and Greek, as well as into Russian. He thanks the translator, Dr. Hurd, for "the assiduity, painstaking, and accuracy" with which he has done his work. This is not an idle compliment, as those who put to it the severer test of a knowledge of the mother-tongue will say. The work of translating has evidently been done with an enthusiasm which can only be felt when the translator is in perfect *rapport* with the author.

In the translator's preface is a very pleasant and comprehensive *résumé* of the various publications of Dr. Dujardin Beaumetz, which number thirty-two. Among them are many important monographs embracing a wide range of subjects.

The "Leçons de Clinique Thérapeutique," published in Paris from 1879–85, is the most important of his works. The first volume treats of the therapeutics of the diseases of the heart and digestive tube; the second, of the diseases of the liver, kidneys, and lungs. The work under consideration is the third volume of the series.

The author has been extremely happy in the manner in which he has correlated physics, anatomy, histology, physiology, and pathology with the therapeutical aspect of the subject with which he is for the time dealing. He sketches these accessories with a bold and masterly hand, in order to throw into a greater prominence the treatment of the disease, which never loses its central place in the foreground.

These can be considered models of what therapeutical lectures should be, namely, a clear, succinct, and careful exposition of the remedies and measures found useful in the relief of the various diseases to which a physician is called to minister, with a sufficient consideration of the physiological facts to show that these remedies and measures are used in consonance with theories dictated by reason and intelligence.

Applied Medical Chemistry. A Manual for Students and Practitioners of Medicine. By Lawrence Wolff, M.D., Demonstrator of Chemistry, Jefferson Medical College; Member of the German Chemical Society, the Philadelphia County Medical Society, the Philadelphia College of Pharmacy, etc. Philadelphia: P. Blakiston, Son & Co. 1885.

The aim of this book is to set forth in a simple and concise manner the methods of chemical analysis, and to instruct the student in the practical application of the chemical principles set forth in the ordinary text-books. Only those subjects are treated of which have to do with medical chemistry, the object being to furnish to the student, in one small volume, the practical instruction suited to his wants, and which he would otherwise have to search for in voluminous treatises on general chemistry. The work is divided into five parts, dealing with Apparatus and Manipulations, the Chemistry of Poisons, Physiological Chemistry, Excretions and Concretions, and Sanitary Chemistry; there is also an Appendix containing a number of useful and labor-saving tables. The book is intended primarily for students, but it is one which the general practioner, who possesses only an average acquaintance with practical chemistry, cannot well afford to be without. The country practitioner, especially, who may at any time be called upon to analyze the tissues in cases of suspected poisoning, will find much to help him in the chapter on the chemistry of poisons. The fourth chapter, containing instructions on the analysis of the urine and fæces, is also one that will often be consulted with advantage.

Massage in Headache.—Nordström says that certain forms of hemicrania, accompanied by points of induration and tenderness on pressure, are of muscular origin, and are due to chronic inflammation. In such cases he recommends massage, asserting that it never fails to give relief.—*Rivista Clinica*, No. 9, 1885.

Subcutaneous Emphysema in Croup.—Dr. Franz Torday, reports in the *Orvosi Hetilass*, No. 35, 1885, a case of a child, three years old, who was suffering from laryngeal diphtheria. One morning, after the patient had had a number of very severe suffocative attacks, the writer noticed an elastic crackling tumor, the size of a hen's egg, between the scapula and the spinal column, on the right side. This gradually extended until the entire head, trunk, and upper extremities were involved in an emphysematous swelling. This gradually disappeared after the dyspnœa had subsided.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 11, 1885.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

DR. WALDSTEIN, from the Committee on Microscopy, reported that he had examined the liver and mesenteric glands presented in behalf of a candidate at the last stated meeting, and that they were the seat of small, *round-celled sarcoma.*

THE PRESIDENT presented, in behalf of a candidate, a uterus removed from the body of a woman having *typhoid fever during the puerperal state.*

AN ENORMOUS DOUBLE HERNIA.

The President also presented a sac and a part of the genito-urinary apparatus, together with ten feet of the large and small intestine, which was in a double hernia measuring forty inches in its greatest diameter and weighing about five pounds. The patient was in the hospital two days. He was fifty-three years of age, German, married, and a cooper, and was admitted to Mount Sinai Hospital October 28, 1885. The patient stated that he had been ruptured on the left side for the last seven years, wore a truss for some time, and experienced no trouble from the hernia. During the last three years his scrotum had become distended and enlarged, and during the last six months he had experienced difficulty in passing urine. He said that he had been ruptured in the right side for three or four weeks. He had been unable to return the hernia on the left side during the last three years, and it had gradually increased in size. All operative interference was precluded on account of the general condition of the patient. The history was one of inflammation of the sac and rupture of the cæcum. Puncture of the sac and escape of gas gave considerable relief, and the patient was then kept under the influence of morphine to such an extent as to render him as comfortable as might be. The specimen was of interest anatomically on account of its enormous size, it being the largest which he had ever seen.

Dr. Wyeth had seen another case within a year, and in which the patient died in the same way with inflammation of the sac, death occurring from shock and sepsis due to rupture of the gut and extravasation of fæces into the sac. That patient was eighty-five years of age, and was a physician in active practice up to the beginning of his last sickness.

CHRONIC INTERSTITIAL MYOCARDITIS—CHRONIC INTERSTITIAL NEPHRITIS.

DR. JOHN C. PETERS presented microscopical slides and the history of a case which occurred in a man sixty-seven years of age, a bachelor, of slight figure, but who had always been in good health, was exceedingly careful of his clothing so as to protect himself against changes of weather, abstemious in his habits, but who always had a coated tongue and a great tendency to constipation. In early years he had suffered from fever and ague, and fancied that he had occasional returns of the difficulty.

About the 10th of May last he called to see Dr. Peters, who saw that he looked so sick that he forbade him going farther, as he had intended to do to transact some business, and sent him home. At that time the patient complained of distress, apparently in the stomach, which probably was due to the heart, and which he attributed to eating some salad that was slightly tainted. The patient soon had great difficulty in breathing, marked orthopnœa, but the temperature remained only slightly elevated, never rising higher than 102.5 F. Dr. Peters' first diagnosis was capillary bronchitis, with œdema of the lungs, more especially of the left lung. The patient quickly developed feebleness of the heart, which determined him to call counsel at once, and the conclusion was that the attack of bronchitis and œdema of the lungs had produced so much pressure upon the heart that dilatation of the right side had been produced suddenly. The consultants were Drs. Flint, Loomis, and Leaming. The urine was passed in large quantity, and it contained a few casts. Although his urine had been repeatedly examined every year, and examined a few months before the attack, nothing abnormal had been found. The patient slowly recovered, albumin entirely disappeared from the urine, breathing remained slightly impeded, always a little short of breath, and he was left with dulness on percussion and feebleness of respiration over the left side; and examining him from time to time, Dr. Peters thought he detected a friction murmur over the heart, and also over one pleural cavity, but these symptoms were not detected by either of the three consultants. In Saratoga, during the summer, he had another attack, from which he recovered and came home, and was able to walk about somewhat for a month or more. His urine was examined every day, but no trace of albumin could be detected. He then had another relapse, with great difficulty of breathing, with albumin in the urine, and died at the end of ten days.

At the autopsy the heart was found somewhat enlarged, with the pericardium adherent. From sixteen to twenty ounces of fluid were found in one pleural cavity, and a very small quantity in the other. There were no valvular lesions of the heart. There were some old pleuritic adhesions at the apex of the lung opposite the pleural cavity containing the largest quantity of fluid. Microscopical examination demonstrated the existence of chronic interstitial myocarditis, and also of chronic interstitial nephritis.

DR. PRUDDEN thought the fact that a person in this walk of life should have pleurisy and pericarditis without having given rise to symptoms was worthy of note, because such persons would be very likely to know whether or not they had been sick. Evidence of old and severe inflammations affecting the pericardium and the pleura, without any clinical history whatever, were very frequently found at autopsies on the bodies of persons from the lower classes of society, who were too poor to be able to stop work, and who went on without knowing that they were sick.

DR. VAN SANTVOORD asked concerning the specific gravity and the quantity of the urine.

DR. PETERS replied that the specific gravity of the urine was on an average about 1.020, and that at times the quantity was large. During the acute portion of some of his attacks the quantity was quite small.

DR. VAN SANTVOORD said he asked the question because not long since he made an autopsy in which he found pure fibroid change in the kidneys in a case in which the quantity of urine sank as low as ten ounces daily, and the amount of albumin was said to be merely a trace, thus showing how slight changes might exist in the urine even when the kidney lesions were exceedingly grave. There were also pleuritic adhesions, and the left ventricle of the heart was dilated and somewhat fatty. Death took place evidently from a large accumulation of fluid in the pleural cavity.

DR. WALDSTEIN said that those who had occasion to make many autopsies frequently found the condition of the kidneys described by Dr. Peters, without the clinical history of the disease. On the other hand, he would recall the discussion which occurred in the Society last year with regard to the quantity of albumin in the urine, and how often we had occasion to examine the urine of people who had not complained of feeling ill, and with negative results, and some day we are surprised to find an appreciable quantity of albumin in the urine. It would appear from that discussion, and from what was well known, that it was very important to examine the urine frequently before reaching any conclusion concerning the soundness of the kidneys.

The President said that in the discussion to which Dr. Waldstein referred, Dr. Janeway reported a case which came under his observation, one in which there was the most remarkable manifestation of albuminuria which he had ever witnessed. Dr. Janeway finally found that it depended upon mental effort of any kind, and so susceptible was the patient to the influence of mental work that albumin appeared in the urine after reading a page or two of something which engaged his attention.

Dr. Wesley M. Carpenter said he had had occasion to examine microscopical sections similar to those which Dr. Peters had presented, and had found that the fibroid degeneration of the heart extended from the endocardial surface, with the muscular tissue in a normal condition close up to the pericardium, which was thickened and adherent. The kidneys showed a marked increase of intertubular tissue, but the epithelia were in a remarkably good condition; for the most part the epithelial cells were in position, their nuclei were distinct, and the free borders of the cells had undergone only very slight disintegration. In general there was only a very slight amount of granular matter within the lumina of the tubules, what there was being due probably to the process of hardening.

Dr. Van Santvoord presented a specimen of

HYDROCELE

removed from the body of an infant two months of age and a foundling. It was brought into the asylum at the age of one month, with a hydrocele which extended as far upward as the external ring upon both sides.

Dr. Van Santvoord also presented a specimen of

LUPUS OF THE LARYNX,

taken from the body of a boy, fourteen years of age, who had been an inmate of Randall's Island Hospital for a number of years. He had lupus of the nose, which gradually progressed, and at the time of death it had destroyed entirely the nose, the upper lip, and the alveolar process between the canine teeth, the hard and soft palate, and the nasal septum, and the body of the sphenoid was entirely bare and rough. In the pharynx no lesion could be observed. In the larynx was found a general thickening of the mucous membrane, and that lining the ventricles and their immediate neighborhood was dotted over with a number of small, nipple-like elevations, the summits of which were about the size of a medium-sized pin-head. The immediate cause of death was a marked feature of interest in the case. The boy had lived until about three days of his death in comparative comfort, and then developed intense headache, which passed on to delirium, coma, and death. On removing the calvaria it was found that the base of the brain was coated with a thick, dense layer of lymph, the distribution of which was about the same as that seen in tubercular meningitis, although no tubercular lesions were observed. The dura mater over the cella turcica was dark, sloughy looking, and the body of the sphenoid was necrotic. The lungs were œdematous, and the heart was fatty; the liver, spleen, and kidneys were markedly waxy; the mucous membrane of the small intestine was somewhat thickened, but gave no distinct reaction to iodine, and the large intestine appeared normal.

The case was of some interest with regard to the alleged identity of lupus and tuberculosis. In view of the extent of the lesion and the absence of general tuberculosis, it seemed to Dr. Van Santvoord that the case might be accepted as one pointing toward the non-identity of the two affections.

Dr. Putnam-Jacobi remarked that the absence of general tuberculosis should not justify skepticism concerning the tubercular nature of lupus, for the absence of general tuberculosis was the rule in all cases of external local tuberculosis. Although Hueter had urged the excision of bone rendered carious through tubercle, as an important element of prophylaxis against general tuberculosis, saying that this was to be considered, even if only one case in twenty were really liable to become tuberculous. Yet König, in his monograph on osseous tuberculosis, has shown that out of one hundred and sixty-eight cases observed by himself, generalized infection occurred in only sixteen; and in all these it followed an operation for the relief of the local disease. The proportion of liability in König's statistics doubles that suggested by Hueter—1 to 10 instead of 1 to 20. But in both the proportion of cases is very large where a lesion, unquestionably tubercular, remained throughout limited to the locality at which it first manifested itself. There would be, therefore, nothing extraordinary in lupus, though a tubercular disease, following the same rule.

Dr. Van Santvoord said he did not wish to be skeptical with regard to the identity of the two affections, but he simply spoke of the case, from a clinical standpoint, as one which might throw some doubt on the supposed identity of the two affections. He was not permitted to remove the sphenoid bone, and therefore it could not be examined for bacilli. The other half of the larynx was in the hands of Dr. Biggs for examination.

The President said with reference to the question of propriety of operative interference in tuberculosis of bones, in order to prevent a general dissemination of the disease, it was one which was generally accepted among surgeons in New York, and that a bone suspected of being the seat of tubercular osteitis should be operated upon early for the purpose of removing the infective foci.

Dr. Van Santvoord said that the character of the process in the larynx and in the region of the ventricles was confirmed by the description given by Turck, and certainly was one which did not resemble what he had been accustomed to see in tubercular disease of the larynx. He did not know that that distinction was one which could be borne out by a large number of cases.

Dr. Prudden said the question was one to be decided by microscopical examination. It had been shown that tubercle bacilli were present in a large proportion of cases of lupus, and if it was understood that the tubercular lesion was caused by the presence of the tubercle bacillus it had been established that lupus was tuberculosis.

CANCER OF THE STOMACH—TUBERCULOSIS OF THE RETRO-PERITONEAL GLANDS.

Dr. Waldstein presented two microscopical slides illustrating two different diseases in the person of a man who, when he was sixteen years of age, had chronic pneumonia involving the left apex, and from which he recovered without its leaving any evidence of its existence. He remained well up to two years ago, when he suddenly showed signs of what he thought was intermittent fever, and for the last two years he had this fever appearing every other day, and was treated by all known antipyretics without the least effect on the course of the symptoms.

When he was examined first, two years ago, there was detected a tumor a little to the right of the median line, and the physician reached the conclusion that it was a case of cancer of the stomach without having developed any dyspeptic symptoms. In fact, his digestion was perfect, with the exception of these consecutive derangements which took place from time to time accompanied by fever. Many physicians saw the case in consultation, and the last one, to whom Dr. Waldstein was indebted for the notes of the case, thought he detected an enlargement in the abdomen which seemed to be continuous with the tumor in the epigastrium.

Here, then, was a case considered as one of cancer of the stomach, accompanied by a peculiar form of fever, and also there were tumors found in the abdomen. It was regarded as impossible to reach any positive conclusion concerning the exact character of the case.

At the autopsy a caseous focus was found in the apex

of the left lung, encysted and dry. The bronchial glands were enlarged, and contained many caseous spots. The stomach contained diffuse carcinoma which had no tendency to ulceration, but, on the contrary, the connective-tissue had proliferated more and more, and developed a scirrhous form of affection, and therefore it was easy to understand why the gastric symptoms were not marked.

The retro-peritoneal glands were very much enlarged and degenerated, and contained a great amount of cheesy matter.

This, therefore, was a case where cancer of the stomach existed, which by its nature gave rise to no clinical symptoms; besides, there was caseous degeneration in the retro-peritoneal glands, tubercular in character, without any sign at all of metastasis. It seemed, therefore, that the two diseases had run parallel with each other.

Dr. John C. Peters remarked that it was once regarded that the presence of one excluded the existence of the other.

The President said it had been stated that one retarded the progress of the other.

Dr. Putnam-Jacobi said that Beneke had attributed the predisposition to tuberculosis to the fact that the arteries of the body were all too small; while in the cancerous diathesis they were as much too large. Now it was evidently impossible that any one's arteries should be at once too large and too small, and hence the habitual antagonism of the two diatheses.

Dr. R. W. Wilcox said, therefore the danger in an individual having normal arteries was that he was liable to both diseases.

Dr. T. Mitchell Prudden presented a specimen with the following history:

NECROTIC CYSTITIS.

The specimen was taken from the body of a married woman, aged about thirty, who had a child about two years before her death, and who had been suffering for many months with necrosis of the bones of the left side of the face.

In the last months of life she had paralysis of the right side of the body; complained of pain very low in the back. At one time had difficulty in passing water, so that the catheter was used for some time. Latterly, however, she had urinated without difficulty. Examination of urine showed albumin. Microscopical examination was not made. With the exception of the difficult micturition there were no symptoms referable to the bladder.

At the autopsy were found a tumor involving nearly the entire left side of the pons Varolii, pachymeningitis purulenta over the petrous and posterior portion of the sphenoid bones, purulent meningitis at the base of brain. General peritonitis, with the production of a considerable amount of fibrin and little pus, and the condition of the bladder shown in the specimen, namely, *necrotic cystitis*.

The bladder was dilated and filled with turbid urine. The mucous membrane, in general, was moderately thickened and irregularly mottled with red patches.

Surrounding the urethral orifice was an irregular circular area, entirely denuded of epithelium, about three inches in diameter, which was covered with a delicate œdematous pellicle of connective-tissue, which was irregularly streaked and mottled with a yellowish-white material.

At the edges of this area the intact mucous membrane was thickened and infiltrated with pus, so that the above-described patch had a tolerably distinct, irregular, yellowish-green border.

In places the musculosa near this patch was infiltrated with pus, and beneath it was itself necrotic.

On microscopical examination the above-described patch was seen to consist of a small amount of fibrous tissue, with whose bands were intertwined numerous elastic fibres. Scattered in the meshes of this tissue were numerous crystals of urinary salts, and concentrically striated disks or globules of leucin. It was these latter substances which gave rise to the irregular yellowish streaks and patches described above. It will thus be seen that the abnormal patch of tissue at the neck of the bladder is a portion of œdematous submucous tissue, infiltrated with urinary salts, etc., and bordered with a narrow zone of purulent inflammation.

The specimen is an excellent example of localized necrotic inflammation of the bladder occurring in a paralytic, a form of lesion which is by no means uncommon.

It is of especial interest, however, because it shows the condition of affairs which precedes the casting off of the slough, a state of the lesion which we do not often see. This casting off of the slough, as is well known, may take place piecemeal, or a large patch may separate and come away as a single sheet of necrotic tissue, as was the case in an interesting specimen presented by Dr. Boldt at a recent meeting of the Society.

I present this specimen not only on account of its intrinsic interest, but also because it supplements, in a most instructive manner, Dr. Boldt's specimen, and confirms the truth of the conclusion arrived at by the Microscopical Committee, as reported at the last meeting.

The Society then went into executive session.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE BOWMAN LECTURE—THE DECENNIAL REPORT OF THE REGISTRAR-GENERAL—DR. WILKS ON THERAPEUTICS—COCAINE AND ITS DANGERS.

London, November 21, 1885.

The "Bowman Lecture" for this year at the Ophthalmological Society has just been delivered by Dr. Hughlings Jackson. Dr. Jackson commenced his lecture by referring to the question of the division of labor. Things, he said, became increasingly complex. There was no exception. Our profession was now very complex, and he instanced the various specialties. As to specialists, he said the specialty of each came out of, and was a differentiated part of, a wide general knowledge. Specialists, he remarked, had to justify themselves. According to Spencer, the factors in progressing evolution were (1) increasing differentiation, (2) increasing definiteness, (3) increasing integration, and (4) increasing co-operation. That the ophthalmic surgeon had justified himself in the second factor of evolution needed no proof. Then as to the third factor. Each different definite medical worker was working for the whole body medical. His work led to the greater integration of the knowledge of other workers. Each worker helped all the others. For instance, Argyll Robertson had given to neurologists, not merely a new symptom, but a means of investigation of several important diseases. This debt had been paid back by neurologists (Westphal and Erb) who, working in a different field, had shown the diagnostic value of loss of the knee-jerk. Going on to the fourth factor in evolution (increasing co-operation), Dr. Jackson then said each different worker, knowing one subject best, of necessity could not have the precise knowledge of other subjects which other different workers had. Division of labor rendered co-operation necessary. The whole of one disease was best understood by bringing to bear on its direct investigation and treatment different workers in different fields. To give an illustration—the neurologist ought to be able to suspect hypermetropia as a cause of head-troubles, but only the skilled ophthalmic surgeon could accurately estimate and correct it.

We were apt, said the lecturer, to underrate the complexity of some nervous diseases. As an illustration of this, he selected epileptic paroxysms and their after-conditions, and remarked that the symptomatology of

the paroxysm was probably a universal symptomatology. It might be said that insanity was more complex than epilepsy, but this was not so, since epileptic paroxysms were not unfrequently followed by temporary insanity. The study of epilepsy, therefore, involved the study of some cases of insanity.

The various symptoms of epilepsy were then discussed at some length, with frequent reference to the experimental results obtained by various investigators in the field of practical physiology. Coming back, then, to the point from which he started, Dr. Jackson observed that it was not possible for a neurologist to scientifically study this exceedingly complex disease without availing himself of the work done by different specialists. The neurologist needed the aid of the psychologist, of the physiologist, and of the ophthalmologist. After detailing the various ocular symptoms, Dr. Jackson advanced an hypothesis, as to the organ of mind, at once ingenious and elaborate, but to which I cannot hope to do justice within the compass of a few lines. He submitted that we should adopt the hypothesis of evolution, according to which the whole nervous system was a sensori-motor system, representing all parts of the body, and suggested that all parts of the body were represented in each of three levels of evolution—representative, re-representative, and re-re-representative. We ought strictly to speak of four levels. Representation increased in differentiation (complexity), definiteness (speciality), integration (intricacy), and in number of inter-connections (co-operation) from lowest centres to highest centres ("organ of mind"). The "organ of mind" was nothing else than a series of centres representing or co-ordinating all parts of the body.

Reverting, then, to epilepsy as a disease of the organ of mind, Dr. Jackson showed how every organ of the body might be affected and every department of the nervous system involved.

The Report of the Registrar-General for England for the decennial period, 1871–80, has just been issued. I cull from it a few notes which may be of interest. The mean annual death-rate has fallen to 21.27 per thousand, yet the gain from this has been very unequally distributed. The male death-rate has fallen more than four, and the female death-rate just over six per cent. since the preceding decennium. But the gain has been more in the earlier than in the later periods of life, which indeed show an increase in the death-rate. Dr. Ogle, in a letter accompanying the report, attributes both the lessened death-rate and its inequality at different ages to the various sanitary reforms which have been pushed on of late years.

The death-rate from zymotic diseases has decreased, except that from whooping-cough and small-pox, respectively. The former has remained stationary; the latter shows an increase due to the epidemic of 1871–72.

During the past decennium there has been eight districts in England and Wales (out of 647), in which the mean annual rate was under fifteen per thousand, and ninety-three in which it was between fifteen and seventeen.

Some interesting information is given as to the varying mortality of different occupations. The first place for longevity is given to ministers of religion. I regret to see that the mortality of our profession is much higher (as 11 to 5).

Dr. Wilks has lately been giving an address before the Midland Medical Society, and saying some wholesome truths in his own inimitable way. I am afraid some of his statements were calculated—at any rate when freshly heard—to shock some of our modern therapeutists. For his part, he said, he did not wish for any more drugs. Of what use would they be to us? What was the use of putting edged tools into the hands of children who did not know how to use them? After referring to some of the errors of past generations, Dr. Wilks proceeded to give some modern illustrations. "I see," said he, "a lad with pleuritic effusion which has pushed down his liver; the medical man had overlooked the presence of water in the chest, but had discovered the liver below the ribs. He considered this to be enlarged, and gave the boy mercury to reduce it. Now, is it not fortunate that mercury had not the wished-for power in reducing a healthy liver to half its size? Again, I see people with osteitis deformans, and other cases where the bones are enlarged, and iodide of potassium is almost universally given, but it never does any good. Again, I exclaim, how fortunate is this! Could iodide of potassium absorb bone, what a responsibility would rest on the medical men who prescribe it, and in what a condition would all the skeletons of civilized people be! Another example, the hypertrophied spleen. Nearly all patients with this affection are given quinine and iodide and bromide of potassium, in order to reduce it. How thankful I am that these attempts are ineffectual; for if these drugs could absorb healthy spleen-structure, what a mass of people would now be spleenless!"

After experiencing a long run of success, coupled with unqualified laudation, cocaine is now beginning to have some drawbacks and dangers in its use pointed out. At a recent meeting of the Ophthalmological Society, Mr. Nettleship, ophthalmic surgeon to St. Thomas' Hospital, said his suspicions had been roused by the occurrence of a serious run of cases of panophthalmitis at St. Thomas' Hospital, while, at the same time, his cases at "Moorfields" did well. He attributed it to the use of cocaine. Several other ophthalmic surgeons confirmed Mr. Nettleship's experience. Mr. Story, of Dublin, suggested that solutions of cocaine might be made up with saturated solutions of boracic acid. It subsequently transpired, in the course of the discussion, that the solutions of cocaine are actually thus made at "Moorfields" Hospital.

PAPAL AND TALMUDICAL OPINIONS ON CRANIOTOMY.

To the Editor of The Medical Record.

Sir: A few days ago the daily papers reported from New York that the Roman Catholic physicians in that city were in receipt of a circular containing a declaration by the Pope that the killing of an unborn infant is never right, even when the life of a mother can be saved in no other way.

It may be of interest to learn the rabbinical view on this question which bears upon the surgical operation known as craniotomy, that is generally practised by the profession in cases where a choice is forced between losing two lives, and saving one by hastening the end of the other.

The *Mishna*, which is the name of the earliest collection of rabbinical opinions and decisions, compiled by Rabbi Jehuda Hanasi in the second century C.E., contains in tract *Oholoth* VII., 6, the undisputed decisions that, "in case of a dangerous parturition it is justifiable to kill the unborn infant in order to save the mother, as her life precedes its life." Such operation is, however, not permitted after the infant has already been partially born, as in the latter case the maxim applies: "One human life must not be set aside on account of another."

Rashi, the commentator of the Talmud, explains in Sanhedrin, folio 72*b*, the reason of the distinction between these two cases in the following way: "The unborn infant is not yet a *distinct personality* with an *independent* life (*Nepheth*), hence the regard of saving the mother's life is to prevail; while in the second case its individuality is established, hence the legal principle must apply that one life must not be destroyed to save another." The authoritative Rabbinical Codes of Maimonides (twelfth century) and of R. Joseph Caro (sixteenth century) adopted the decisions of the Mishna as the rule of Jewish law.

It must be conceded that the rabbinical view on this subject is in full accordance with common sense and with the highest regard for the sanctity of human life.

Dr. M. Mielziner,
Professor in the Hebrew Union College.

Cincinnati, November 25, 1885.

A NEW FIELD FOR YOUNG DOCTORS.

To the Editor of The Medical Record.

Sir: In a recent number of The Medical Record I noticed an article under the above heading, having especial reference to the new Congo Free State. I wish to say a few things concerning the field in the East.

There are a few ports out here where a young man could build up a good paying practice. I know of two such, while there are three others which would now furnish a living, with the prospect of a good increase; but it would hardly do to count on these places, as they might be occupied before any person who reads this might reach them. The work for foreigners in these parts is mostly in the hands of British practitioners, who have done very well financially, and usually dispose of their places to others of their own people before retiring to live on their accumulated wealth.

Another branch of the Eastern work is, however, quite open. A small handful of physicians are at present ministering to the 350,000,000 Chinese. A few are engaged also in Siam and Burmah, and recently Corea has been occupied by three of our profession. These persons are connected with some one of the missionary societies, and are doing a more extended practice than they could ever hope to do at home.

To any who may be moved by a missionary spirit, coupled with a love for their profession and a desire to be foremost in imparting its blessings to those who have it not, my remarks will well apply. None without such motives need consider the work. The question as to proper spiritual qualifications must be decided by the individual to whom the especial rewards of such a life-work will present themselves. I wish especially to mention some of the more temporal inducements of such a work.

In the first place the need is very great, and the missionary doctor has the consciousness of filling a long-felt want, which is more than he would probably be conscious of in work at home. His opportunity for gaining a wide medical and surgical experience is unparalleled. He has unlimited opportunities for continuing his scientific studies in interesting and unexplored fields, and of becoming an authority in various lines of research.

Socially, he may occupy a higher position than in practice at home, for while it is true that foreigners and often natives in the East look down upon the missionary when he comes as a preacher, they receive the doctor quite warmly. Should he chance to reside in a capital he will, doubtless, be called upon to visit the palace and treat its royal occupants. He will be on friendly, and probably intimate, terms with the consular and diplomatic service, together with the naval and military representatives of his own and other lands, thus gaining a polish and breadth of understanding that he might fail to get even in extensive travels. Away from the ports and capitals, he would still have the association of missionaries of various nationalities, and as these persons are usually "gentlefolk" in every sense of the word, the effect of association with them would be much the same as in the other case, while the medical and scientific inducements would be even greater.

It might be an inducement to know that the missionary physician is expected to live as a gentleman. It would never do to have him badly housed, as he is too expensive an article to be lost after going to the expense of sending him abroad and supporting him while he gets the language. For the same reason he must not be badly fed or clothed. His position demands intelligence, therefore he must take papers and other publications and read them. Servants are so cheap and good, and his time is so precious, that it would be folly for him to waste it in menial service; his position among both foreigners and natives would not allow of this either.

It must also be borne in mind that the East is not out of the world as it once was. India is as much like England as they can make it, further around we find many select little communities as at Singapore, Amoy, Foochow, Ningpo, Tientsin, Nagasaki, Kahe, and others, with their stores, telegraph, and newspapers, while at Hong Kong, Yokohama, and Shanghai we find genuine foreign cities with a great deal of oriental elegance thrown in, and with their very complete stores of all kinds, extensive shipping, telegraph lines, daily papers, cathedrals and churches, beautiful drives, and all manner of places of amusement, the foreign residents come to feel so contented with their new homes as to often prefer them to those they have left. These places form depôts from which missionaries in the interior are continuously supplied with fresh news and stores.

The qualifications necessary for the medical missionary work are health of body and mind, a cheerful spirit, good common sense and judgment, a thorough education and considerable practical experience, together with earnest sympathy with the work and consecration to it. It is very unwise for a young man to come to the East, direct from school, without any real practical knowledge. He may be at once called to treat some important personage, where he will feel his defects most keenly and may do something rashly that will greatly injure himself and his associates. If this be not the case he will, in all probability, be crowded with patients of a lower order, and what can a young man, with no experience and a head full of confused ideas, do with twenty to one hundred patients a day? He will profit by it in time, but it is a hard experience both for himself and his patients. For this work a man should have at least a year's experience in a first-class hospital, or its equivalent of outside practice. To such the way is clear and the East will accommodate all who may come.

H. N. Allen, B.S., M.D.,
H. C. M. Customs Surgeon.

Seoul, Corea, October 8, 1885.

Aviarian Surgery. — Dr. Walter F. Morgan, of Leavenworth, Kan., writes: "*Apropos* of the interesting article in your issue of the 7th ult., allow me to add another instance, which may be called aviarian surgery, related to the writer, in 1876, by the late Joseph O'Brien, Esq., of Cleveland, O. On going into his barn Mr. O'Brien discovered a swallow's nest, and being a natural observer and lover of animals, he climbed to the nest and found in it two young swallows, one being smaller and less vigorous than the other, and having a slighter covering of feathers. Upon taking the young bird in his hand, he was astonished to find one of its legs very thoroughly bandaged with *horse-hairs*. Having carefully removed the hairs one by one, he was still more astonished to find that the nestling's leg was broken. Mr. O'Brien carefully replaced the bird in its nest, and resolved to await further developments. Upon visiting the 'patient' the next day, the leg was again found bandaged as before. The bird-surgeon was not again interfered with, and the case being kept under observation, in about two weeks it was found that the hairs were being cautiously removed, only a few each day, and finally, when all were taken off, the callus was distinctly felt, and the union of bone evidently perfect, as the bird was able to fly off with its mates. Such instances may seem incredible to those not yet prepared to fully accept the axiom of the scientists, viz., 'that the intelligence of animals differs from that of man only in degree, and not in kind'"

New Instruments.

A NEW PHARYNGEAL CURETTE.

By WILLIAM A. DAYTON, M.D.,

SURGEON TO THE EYE, EAR, AND THROAT DEPARTMENT, HARLEM DISPENSARY, ETC., NEW YORK.

No perfectly satisfactory instrument, so far as the writer is aware, has been devised for the removal of vegetations and adenoma of the pharyngeal vault.

The curette illustrated above has proved so useful an instrument in my practice that I am pleased to make it known.

The original instrument has been used by myself and friends for more than six months, and, in over thirty cases, it has effected all that could reasonably be expected.

The instrument is free from the objections to curettes, forceps, galvano-cautery, etc., used for the same purpose, in that *there is no danger of injuring the adjacent normal tissues.*

In contour the tip of this curette corresponds with the tip of a uterine curette, save that the former is more flattened on its convexity. It has one lateral (right) cutting edge, and is attached to a *flexible* shank, admitting of alterations in the curve to suit individual cases.

The shank should be so bent as to allow the tip to pass well up behind the soft palate; then the manipulation, which scarcely requires explanation, consists in rotating the instrument from left to right.

Upon withdrawing the curette, the diseased tissue removed will be held in the fenestra, and will not drop into the pharynx or larynx.

Except in the cases of nervous children, the operation can be performed without an anæsthetic. There is no pain whatever attending it. Again, the employment of a retractor is not necessary, as there is no danger of injury to the soft palate, etc.

The simplicity of the instrument forbids further description, and I commend it to the profession in the belief that it will meet the purpose for which it was designed.

As indicated in the drawing, Meyrowitz Bros., of this city, have made all of these curettes now in use.

121 WEST 125TH STREET.

THE GAIT OF NERVOUS PEOPLE.—MM. Gilles de la Tourette and A. Loude, in order to determine the difference between the manner of walking characteristic of healthy people and that of those suffering from nervous diseases, have adopted the following method: A large sheet of wall-paper is laid on the floor, and a longitudinal line is marked in the middle. The feet of the person experimented on are rubbed with rouge. After the necessary calculations the impressions are reduced in size and photographed. Before studying locomotion in its pathological aspect, the experimenters ascertained the character of progression in a normal state. In each case the length of the foot was taken, and the impression left by it. The width between the feet during the act of walking was also taken; the measurement of the angle formed by the opening of the feet, and its relation to the axial line, traced on the paper. The following conclusions were drawn from the study of patients with bilateral and unilateral lesions, from the onset of the affection until the end: The pathological step is more regular than that of a subject in a normal condition, both in length and the lateral separation of the feet; also the angle formed by the opening out of the feet.—*British Medical Journal.*

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 29, 1885, to December 5, 1885.

VICKERY, R. S., Major and Surgeon. Relieved from the assignment as Acting Medical Director, Department of Colorado, to date the 16th inst. S. O. 200, Department of Colorado, November 23, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending December 5, 1885.

AULICK, HAMPTON, Surgeon. Ordered to Alliance as relief of Surgeon G. P. Bradley.

BRADLEY, GEO. P., Surgeon. Ordered to Naval Hospital, Philadelphia.

SHAFER, JOSEPH, Assistant Surgeon. Detached from Naval Hospital, Philadelphia, and ordered to the Minnesota.

GAINES, J. H., Passed Assistant Surgeon. Detached from Naval Hospital, Washington, and ordered to the Dolphin.

GONORRHŒA IN THE YOUNG.—Dr. B. H. Phelps, of Corry, Pa., sends us the following item: "In the issue of THE MEDICAL RECORD of November 14th is an article on 'Gonorrhœa in the Young.' I was not aware that such cases were so unique. I had three such cases this fall in one family, the patients ranging from between three and four to between five and six years of age. The two older were girls, the younger a boy. The little boy and one of the girls were brother and sister; the other little girl was a cousin visiting in the family. The sister was the first attacked, and I cautioned the mother about letting the other children play and sleep with the diseased child, but the precautions were not carried out. I directed the mother to question the little girl, and learn, if she could, the source of the disease. This she told me she did, and satisfied herself where it came from, but she did not tell me."

REGARDING FRESH PAINT AS AN ABORTIVE AGENT.—Dr. James L. Gardner, of Voluntown, Conn., sends the following: "I notice that several of your correspondents are inquiring regarding the above matter. I am a strong believer in the affirmative, *i.e.*, that fresh paint, mixed with spirits or the oil of turpentine, will cause a pregnant woman, if the odor is inhaled, to abort. In January, 1883, I was called to see E. G——, aged thirty-eight, married, in New London, and an honest, intelligent lady. She had miscarried shortly before at four months. Had borne two living children; no other miscarriages. Dr. N—— had seen her at the time of her abortion, and, after administering to her needs, left, assuring her 'she would be all right.' I found the patient had been 'painting a

little, just to suit her fancy, with 'turpentine paint,' and no other cause could be ascribed for her aborting. She had ovaritis, pelvic peritonitis, and a great amount of pain in the uterus and along the right Fallopian tube. The uterus remained enlarged, although the fœtal contents were discharged, and there was a state of great inertia of the organ. I prescribed opiates, tincture of iodine externally, and hot carbolized vaginal douches twice daily, with an occasional aperient to move the bowels. The case recovered after a protracted siege of several months. The second case I refer to is of Mrs. G. H——, aged twenty-eight, married, but living alone. She became pregnant, and at about two months took, as she informed me, a good dose of oil of terebinth. I found the uterus in a state of inertia, considerably inflamed and swollen, with some pelvic peritonitis. It resulted favorably, but took nearly double the time of 'spontaneous' abortion. I consider the poisonous element in new paint to be *the turpentine it contains*. Should like very much to hear further on this subject from the profession. Old women are full of 'traditions' relating to this subject."

Thomas Latham, of this city, also writes on the same subject: "Respecting 'Fresh Paint and Abortion,' in your last 'Medical Items,' a little reflection upon the chemical nature of paint will perhaps elucidate the question. The odor which we commonly know as that of fresh paint is that due to the volatilizing oil of turpentine contained in the paint, and in some degree to the boiled linseed oil. I think Dr. Eliot in error when he speaks of 'colica pictonum' produced by this. Painters never suffer from the 'fresh paint,' but from direct absorption of lead, from getting it upon the skin, underneath the finger-nails, etc., and also directly into the stomach by eating their lunches with unwashed hands. Their 'colica pictonum,' I take it, is Nature's effort to get rid of intestinal obstruction due to cessation of peristaltic action. I need not remind medical gentlemen of the well-known abortefacient powers of the volatile oils. Many women are also aware of them. Oleum juniperis sabinæ is the favorite, and is frequently demanded in drug-stores. May it not be reasonable to infer that the inhalation of the vapors of these volatile oils has the same effect as taking them into the stomach. I last week produced an excellent 'fresh-paint' odor by making a decoction of the fresh tops of Thuja occidentalis, sent from Canada by a friend to a rheumatic customer."

Abnormal Mobility of the Tongue, with Ability to Project it into the Naso-Pharynx.—Dr. Phelps, of Corry, Pa., writes: "A man who lives about a mile from this city, who is about forty-five years of age, came to me about one year ago for the removal of a polypus from the nose. I saw him several times pass his tongue into the naso-pharynx with perfect ease. The tongue is slightly pointed, and the frænum linguæ is apparently absent for some distance under the tongue. There is nothing abnormal in the formation of his mouth. He says he has possessed this ability for twenty years."

Arrest of a Threatened Abortion.—Dr. R. C. MacDonald, of Chelsea, Mass., writes that in the summer of 1884 he was called upon to treat a lady for prolapse and anteversion of the uterus. Under suitable treatment the trouble was nearly removed. He was called again to see her in December, on account of a profuse hemorrhage. Although the patient had not nursed her last child since May, she had not menstruated, and as this was about her time Dr. MacDonald supposed at first that the menses had returned. But on examination he found the os open and an ovum so low down that it could be grasped by the two fingers. He inserted a light tampon of cotton wool, gave opium, and ordered absolute rest. He writes: "To my surprise the hemorrhage ceased in a short time and the ovum was retained. I watched the case with interest. The patient went on from that time with all the usual signs of pregnancy to full term, and, on the 10th of July, 1885, I delivered her of a healthy full-sized boy, who was, I feel certain, the very ovum I had held between my fingers."

A Fine Opening for Young Physicians.—It is stated that there are but five physicians in Belgrade at the present time, all the others having been sent off with the Servian army. Of these five one does not practise, and another is the court physician and does not attend ordinary mortals, so that the available force is reduced to three. The population of Belgrade is in the neighborhood of 30,000. There will hardly be a very extensive emigration from this country to Servia, however, for the language is one of the most difficult to learn in all Europe; but one would suppose that Vienna would gladly unload some of her surplus doctors on the Serbs. Physicians are also wanted for the Servian army. The pay averages about $650 per annum.

Vaccination.—Dr. Samuel W. Francis says that the only thing to fear from excessive vaccination with bovine virus is Cattlepsy!

Adjustable Forceps.—Dr. Henri Haman has devised a form of obstetrical forceps in which the extremity of the spoon is provided with a double joint, so that the bars may be approximated, thus reducing very considerably the width of the blades. After the instrument is introduced and the blades locked the bars may be separated by means of an attachment in the handle so as to restore the spoons to their usual shape. When closed the blades are but a little over an inch in thickness at their widest part.

"Yellow Fever and the Efficacy of Quarantine."—Dr. A. N. Bell, editor of *The Sanitarian*, writes: "Under this title, in The Record for November 21st, Dr. S. T. Armstrong sends you an excerpt from *The Sanitarian* for September last, with remarks wrongfully attributing to me an animus toward the Marine Hospital Service. I have no animus whatever against it or any one belonging to it, and it is both a subject of surprise and regret to me that any one, in either private or public life, but especially in the latter, should ever construe my remarks and criticisms upon subjects and practices which appear to me to be in conflict with health as having any other personal bearings than personal and public health. In the particular case referred to by Dr. Armstrong he attributes my remarks, when applied to the quarantine under the auspices of the Marine Hospital Service, as compared with remarks previously made when I was ignorant of the fact that the subject at issue had any relation whatever to the Marine Hospital Service, to an unfriendly bias. The case was, briefly: When I supposed the health officer of the Port of New York wholly responsible for admitting the infected vessel to *pratique* without disinfection, I pointedly inquired, 'Why, in the interest of life, the public health, and of commerce was not the ship disinfected within twenty-four hours from the time of her arrival, . . . instead of being detained nine days and then sent on her way *via* New York bearing disease and death?' To this animadversion on his service Health Officer Smith took exception, addressing me a note which I published in *The Sanitarian* for September, stating that the vessel in question arrived at the New York Quarantine with a *clean* bill of health from Dr. Wm. P. Orr, the quarantine officer of the Marine Hospital Service at the Delaware Breakwater, with written addition—'This bark, John Gibson, has been cleaned and fumigated.' My published remarks, after receiving this note, were, in part, as quoted by Dr. Armstrong, and in addition, 'It has at least demonstrated to the Health Officer of New York that such cleansing and fumigation should not again pass his scrutiny.' My opinion of the utter worthlessness—ay, more—the danger to the public of all such service is so well and so long known by frequent repetition as to leave no room whatever for any one to construe it as personal.

. The fault of Dr. Smith, as apparently recognized by himself, according to his note, was that he accepted the averment of Dr. Orr, that the vessel was *clean*. He did not take the same exception to such authority as he has learned the necessity of taking to 'clean' bills of health from abroad, and the result was as stated. But to the worthlessness of the kind of service rendered at the Delaware Breakwater, Dr. Armstrong furnishes additional evidence, for he states that, notwithstanding 'Health Officer Smith decided it would be safe to honor the bill of health, he took the precaution to fumigate the vessel again.' If, in the light of such evidence of their utter worthlessness and danger, such mere perfunctory 'fumigations' as those practised in the case of the John Gibson, no matter by whom, are persisted in, instead of disinfection and cleansing, it is sincerely to be hoped that the time is not far distant when those who practise them will be indicted for criminal incompetency."

Quinine in High Altitudes.—Dr. S. D. Bowker, of Kansas City, Mo., writes: "In a recent number of The Medical Record, Dr. Ralph M. Cole, of Idaho Springs, Col., in a report of a case in which quinine was used, says, 'it is necessary to observe great care in the use of this drug in high altitudes.' For the benefit of parties with a short experience in high altitudes I will say, that ten years in Colorado, four of which were spent in Central City, only four miles from Idaho Springs, taught me that Dr. Cole's conclusions will not do as a guide to practice. I went there in 1871 with a similar impression to his, without knowing just how I got the information. What was called 'mountain fever' was then raging with a heavy death-rate, and I found to my regret that small doses of quinine would not meet the emergency. I was informed by Dr. L. C. Tolles, who has practised in Central City nearly twenty-five years, that his first years there were spent under the false impression of Dr. Cole. He somehow got the notion that high altitudes contra-indicated the use of quinine, so that he almost discarded it, even in small doses. But, greatly to the benefit of his patients, he discovered that no climate in this country would tolerate, and even demand, as large doses as the high altitudes of Colorado. Ten grains every four or six hours, in a typical case of mountain fever, was not unusual in my practice, and Dr. D. W. King, who was in practice there, tells me he often gave a full ounce during twenty-four hours with the best results. Of course, this was in extreme cases, but, taken with facts known to the older men in practice in the mountains, proves that quinine is generally required in large doses in high altitudes, in any disease accompanied with fever, not only for its anti-periodic effect, but for its sedative action, so often needed to control nervous excitability caused by the unusual electrical conditions in all high altitudes."

Maggots in the Head.—Dr. R. H. White, of Angel Island, Cal., writes that he has found sulphate of quinine a most reliable agent for the expulsion of larvæ from the nasal and other sinuses of the head. Prompt relief to the patient was obtained by the exhibition of quinine in five-grain doses. The writer does not state whether the drug was also used externally in solution.

Giving Urine to a New-born Child and What Came of It.—Dr. E. J. Brown, of Minneapolis, Minn., communicates the following: "In the 'Dutch Account of Hottentot Pathology,' published in The Record of September 5th, mention is made of the custom among midwives of giving the new-born child some of its father's freshly drawn urine. Probably most practitioners are aware that this barbarity still prevails to some extent in parts of our own country. In this connection my father, Dr. I. Brown, recalls a reminiscence which he permits me to send you. Some thirty years since, he had under his care a brother physician who was a slave to the morphine habit. This gentleman related that a few years previous his wife had delighted him with the present of a son (his other offspring being all girls). The old women present demanded some of the father's urine for the babe. The demand was complied with, the infant was dosed, and was soon dead from morphia. The moral is obvious."

To Secure Primary Union after Amputation of the Breast.—In women who have much subcutaneous adipose tissue, Dr. B. Riedel advises the removal of the fat before closing the wound. The presence of much adipose tissue, he says, interferes seriously with union by first intention.

An Instrument for Measuring Albumin.—Esbach has devised an apparatus for the quantitative determination of albumin in the urine, which he calls an albumimeter. It consists of a small graduated tube, which is filled up to a certain mark with urine, to which is added a definite quantity of a solution of 10 grammes of picric acid and 20 grammes of citric acid in a litre of water. The test-tube is then closed with a rubber stopper, shaken so as to cause a thorough admixture of the two fluids, and left to stand for twenty-four hours. The amount of precipitated albumin is then read off from the scale, which is graduated so as to indicate the amount of albumin expressed in grammes contained in a litre of urine.

Tweedledum and Tweedledee.—One of the prominent out-of-town delegates to the meeting of Old Code adherents, recently held in this city, was heard to remark that he didn't observe any great difference between Old and New Code men as to their readiness to consult with the "-paths." He himself could not see any reason why a general practitioner should not consult with an irregular if specialists were allowed to do so; and if he were in a tight place he would rather seek the advice of a well-educated homœopath than of an ignorant member of the regular profession. Where is the consistency in fighting for principles on theory if they are not adhered to in practice?

The End of the Cholera—On October 18th a *Te Deum* was sung in the Cathedral of Valencia in thanksgiving that the cholera had subsided and that the city was entirely free from the disease. It was at first proposed to have a public festival as well, but better counsels prevailed, as it was deemed inappropriate to make merry while so many were mourning their losses, and accordingly the religious function was the only official sign of the termination of the epidemic.

Somewhat Behind the Times.—It is reported that Professor Cheine has decided to discontinue the use of the carbolic spray in the wards of the Edinburgh Royal Infirmary for six months, in order to test whether it has any real merit. He will be somewhat consoled to know that the spray has long since been discarded by most of the leading hospital surgeons in the metropolis.—*London Hospital Gazette.*

A Religious Medical Journal.—Once every year, within the octave of the feast of Sts. Cosmas and Damian, *El Sentido Católico en las Ciencias Médicas*, which, by the way, is one of the best of our Spanish exchanges, displays upon its first page the following invocation: "To the holy patrons of the medico-pharmaceutical profession, Cosmas and Damian, the editorship of the journal 'Catholic Thought in the Medical Sciences' renders its homage, and invokes their powerful intercession to obtain from the Giver of all health the necessary light to defend the doctrine of harmony between revelation and science."

To Increase the Adhesive Properties of Plaster.—Dr. H. R. Kelly, of Galion, O., writes that a sponge, saturated with stronger ether, passed lightly over the surface of adhesive plaster, will cause it to stick firmly to the skin. No heat is necessary, and the plaster will adhere closely over its whole extent. Spirits of turpentine will act in the same way.

Original Articles.

THE TREATMENT OF FRACTURES OF THE UPPER EXTREMITIES.[1]

BY SAMUEL W. SMITH, M.D.,

NEW YORK.

IN presenting my paper, entitled "Original Deductions, based on a Study of One Hundred Cases of Fractures of the Upper Extremities, excluding the Hand," I claim no originality in my general plan of treatment of these cases except in the use of splints which I have invented, and which have, to my knowledge, never been used before. If, in the history of each case coming under my care during the past four years, I present any idea that may hereafter prove a new and substantial benefit to even one unfortunate laborer by shortening the term of enforced idleness resulting from accidental injury, and by bringing him or her out of such term with a useful instead of a crippled arm or joint, I shall consider my time well spent in reviewing my experiences in this line.

That fractures of the upper extremities are very common among children, as well as among older persons, is shown by the following tabulated list:

	6 years and under.	6 to 12 years.	12 to 50 years.	Over 50 years.	Total.
Scapula (3)—Acromion			2		2
Coracoid process				1	1
Clavicle (37)	20	5	8	4	37
Humerus (15)—Surgical neck		1			1
Shaft of	2			1	3
Condyles: T-fractures		1	1		2
Internal condyle	1	2			3
External condyle	1	2	1		4
Epicondyle		1	1		2
Ulna (11)—Olecranon			3		3
Shaft			1	1	2
Head of			4		4
Styloid process				2	2
Radius (34)—Neck of		1			1
Shaft of	4		2		6
Lower end of — Transverse or short oblique	1		9	2	12
Lower end of — Colles'			3	12	15
Total	29	13	35	23	100

Hence it becomes us as surgeons to employ our art in assisting nature's physiological laws of repair by placing the fragments in such a position as will most likely result in a complete union without deformity, and that such a position shall allow as much ease and comfort to the sufferer as possible. This has been my constant desire and aim, both in dispensary and private practice. The above table shows that nearly half of these fractures occurred to children under twelve years of age. Of these, twenty-five were fractures of the clavicle; eight were fractures of the condyles of the humerus, and but one a fracture of the lower end of the radius. In the cases over twelve years of age we have an altogether different state of affairs. But twelve were fractures of the clavicle, three fractures of the condyles of the humerus, and twenty-four fractures of the lower end of the radius. It seems to me important to give a minute description of the kind of fracture as well as of the location, otherwise, in recommending any particular splint or plan of treatment, we may easily mislead the more inexperienced of our profession and thus have a valuable aid in the treatment of those injuries deemed unworthy of a second trial; and therefor it is that I ask your indulgence while I refer to some of the peculiar characteristics of the more important fractures.

Fractures of the clavicle.—Of the twenty-five fractures of the clavicle of children under twelve years of age, twenty-two were transverse or short oblique, having the line of fracture near the outer edge of the middle third, with only slight displacement of the fragments. In some, there being no displacement, the periosteum evidently not having been torn through, the only evidence of fracture was a false point of motion and crepitus; while in the other three cases the fractures were near the middle of the bone, and long oblique in character, with considerable displacement and deformity. Of the eight fractures of persons between twelve and fifty years of age, three resulted from great violence to the upper and outer portion of the shoulder, the line of obliquity commencing near the inner edge of the middle third and running from above downward and inward, developing great displacement of the fragments with much deformity; the outer fragment being drawn downward and inward, so that it lay under and crossed the inner fragment like the letter x. [I think, when this particular kind of obliquity occurs, it is due to the clavicle being forced down across the first rib.] The other five fractures resulted either from a fall on the hand with the arm extended from the side, or a fall on the outer portion of the shoulder. Of these, three were long oblique, the line of obliquity running from the outer portion of the middle third backward and inward, having much less deformity and displacement than obtained in the three cases before mentioned. One was transverse or short oblique near the outer edge of the middle third, with very little deformity, the other being transverse outside the coraco-clavicular ligament, with considerable displacement and dropping of the shoulder. The remaining four cases of persons over fifty years of age, resulted from a fall on the hand while the arm was extended from the side, or from a fall on the outer portion of the shoulder; all were in the middle third, running obliquely backward and inward. In all of these cases, just as the fractures occurred within the attachment of the subclavius muscle, it became alike difficult to overcome its tendency to draw the outer fragment inward and forward.

Fractures of the humerus.—At present I will speak only of those at the lower end of this bone. In speaking of these fractures, please understand me as referring to the condyles or separation of the epiphysis. That such are not infrequent, especially between the ages of six and twelve, is shown by the above table. Of eleven fractures of the condyles of the humerus two occurred in children under six years of age, one of the external and one of the internal condyle: six occurred between the ages of six and twelve; of these one was of the epicondyle, two of the external condyle, two of the internal condyle, and one of both condyles, or the so-called T-fracture. Three occurred in persons between the ages of twelve and fifty years; of these, one was of the epicondyle, one of the external condyle, and one of both condyles, or the so-called T-fracture.

[1] Read before the New York Academy of Medicine, December 3, 1885.

Fractures of the lower end of the radius.—I will not occupy your time in reviewing the more simple fractures of the ulna and shaft of the radius, but will confine my remarks to the fracture of the lower end of the radius—the so-called "Colles fracture." And here a word explanatory of my understanding of a "Colles fracture," for I concede a marked difference between a "Colles fracture" and a transverse or short oblique fracture, which latter has not, under my observation, given rise to the characteristic deformity so particularly described by Mr. Colles, except when we have the fracture transverse through the more cancillated structure of the bone, with the lower fragment splintered and impaction of the upper fragment. All the text-books on surgery which I have consulted omit mention of the peculiar obliquity of this fracture. Mr. Colles' own description in the *Edinburgh Medical and Surgical Journal*, vol. x., p. 182, 1814, deals more particularly with its characteristic deformity and cause, without referring to the degree of obliquity. Prof. Alexander Gardner, of Queen's College, Belfast, in his treatise on "Fractures of the Lower End of the Radius and Clavicle," in 1875, says: "In justice to the man who first described this fracture, we should restrict ourselves to the form or variety which Mr. Colles described." He then asks, "Is the fracture transverse?" and says, "Of twenty-seven specimens examined, nineteen were oblique from before backward, and eight directly transverse," and again asks, "If the transverse fractures had been examined immediately after the accident, would they have been considered directly transverse?"

Erichsen, in his work on Surgery, vol. i., p. 420, says: "Colles' fracture is generally oblique from before backward;" and again, page 421, that a patient died in the hospital twelve days after receiving a "Colles fracture," the wrist presenting the characteristic deformity in a marked degree; and that he made a dissection of the limb and found the line of fracture transverse and about an inch above the articular surface, with impaction of the upper fragment, the lower fragment being somewhat comminuted.

Prof. E. M. Moore, of Rochester, in his very able paper read before the New York State Medical Society, and published in THE MEDICAL RECORD, vol. xvii., p. 305, 1880, says "the fracture is usually oblique." But he fails to describe the special character of the obliquity, and recommends the following treatment, viz.: A small roller or compress under the ulna, and over this and around the wrist, tightly drawn, a few turns of adhesive plaster, about two inches wide, and says that the best results are obtained thereby. This may be so in Dr. Moore's hands, but it utterly failed in mine, except in cases of the short oblique or transverse fracture, without impaction, when I obtained as good results as with any other splint. It was during a trial of Dr. Moore's splint in the treatment of these fractures that I recognized a marked distinction between long obliquity and short or transverse fracture. However, when we have a short oblique or transvere fracture within an inch of the carpal articulation, and a comminution of the lower fragment with impaction, then we have a shortening of the radius, the carpal end of the lower fragment with the carpal bones being drawn backward, the hand also drawn outward and presenting the characteristic deformity described by Mr. Colles. The kind of splint used and the after-management of the case should, therefore, depend largely upon the fact whether the obliquity of the fracture be long or short; and for this reason we have the action of the supinator longus with the extensors constantly drawing the lower fragment upward, and its carpal end with the carpal bones backward and the hand outward, which gives rise to the posterior deformity and appearance of dislocation of the ulna. Hence, as the obliquity is great, the difficulty of retaining the fragments in apposition after reduction is correspondingly great, and, by the drawing upward of the lower fragment, we have a shortening of the radius giving rise to the unnatural convexity over the head of the ulna so common after treatment of these fractures. Dr. Moore, however, claims that the inner deformity over the head of the ulna is due to the giving way of the internal lateral ligament and the triangular fibro-cartilage, the styloid process and sometimes the head of the ulna being thrust through the annular ligament. This may or may not be the case, and is difficult of demonstration. Through the kindness of Dr. Dennis, I was shown a remarkable specimen of so-called Colles' fracture, with dislocation of the ulna, the head of the bone tearing through the annular ligament. This specimen was taken from a woman who had thrown herself head foremost from a third-story window, striking upon her hands. The force of the blow was greater than is necessary to produce a Colles fracture, hence the driving of the head of the ulna through the annular ligament and the comminution of the lower fragment of the radius.

In speaking of these fractures I will use the term Colles' fracture only where the fracture was of the long oblique variety, and gave rise to the characteristic deformity as described by Mr. Colles, and use the words short oblique or transverse where the fracture occurred in the same location, with the deformity less marked, and after the fragments had been brought into apposition, were easily held in their natural position.

There are in my list twenty-five fractures of the lower end of the radius. Of these, two occurred to children under twelve years of age, one of which was transverse, and one a separation of the epiphysis with no deformity. Eleven cases were between the ages of twelve and fifty years. Of these, eight were short oblique or transverse with some deformity, and three were Colles' fractures, deformity well marked. Twelve occurred to patients over fifty years of age, and of these two were short oblique or transverse, with considerable of the characteristic deformity of Colles' fracture, but easily reduced and readily held in position. The remaining ten were Colles' fractures, the characteristic deformity being well marked in all of them.

Treatment.—I will not occupy your time in reviewing the various splints and devices for the treatment of these fractures. Professor F. H. Hamilton, in his treatise on "Fractures and Dislocations," page 194, says of the number of splints and devices for the treatment of the fractured clavicle: "A catalogue of the names only of the men who have upon this simple point exercised their ingenuity, would be formidable, nor would it present any mean array of talents and of practical skill." As much may be said relative to the number of splints and devices for the treatment of fractures of the condyles of the humerus and the lower end of the radius.

The main object to be obtained in the treatment of fracture of the clavicle is to lift the shoulder upward, outward, and backward, and to hold the fragments in apposition. The two splints most commonly used for this fracture are, on the Continent, Desault's, with the axillary wedge, and in this country Professor L. A. Sayre's adhesive plaster splint, and, to some extent, Professor E. M. Moore's shawl or elbow figure-of-eight splint. With these I will briefly compare my splint for fractured clavicle. In the use of Desault's splint for oblique fracture near the inner third of the clavicle, I have never been able to throw the shoulder sufficiently outward to overcome the deformity without seriously interfering with the circulation of the arm, though the forearm, from the fingers to the elbow, be bandaged. Cases are reported where paralysis was caused by the pressure of the wedge upon the brachial plexus. Professor Sayre's splint, properly applied, will overcome any of the ordinary results of an oblique fracture in the middle third, where the obliquity is from before backward; but where the bone is fractured in the great convexity and the obliquity is downward and inward, I have found it insufficient to overcome the deformity, and have also found it to interfere with the circulation of the arm. Its greatest objection, however, is the irritation of the skin by the

adhesive plaster, which in some cases, especially those of young children, excoriates and results in superficial ulceration to such a degree, that several times I have felt obliged to remove the splint in less than a week from its application.

Professor Moore's figure-of-eight splint was an advanced step, and answered the purpose only where the fracture

Fig. 1.

was near the outer edge of the middle third, and transverse or short oblique in character; but where the fracture is near the inner third and long oblique it does not answer its intended purpose, but does the very opposite, for, passing the end of the shawl backward over the shoulder, it presses the outer fragment downward, rather than hold it up in apposition with the inner fragment. Nor does it suffice to draw the elbow backward and inward enough to overcome the action of the subclavius muscle, which, in my opinion, is one of the main factors in drawing the outer fragment inward. This led me to carry Dr. Moore's idea a step farther, by making a clove hitch with a scarf around the forearm well up to the bend of the elbow, passing the loose ends across the back and over the uninjured shoulder. This enabled me to draw the elbow of the injured side farther backward, inward, and upward, and make the humerus a lever and the side of the chest a fulcrum by which I could lift the shoulder of the injured side upward, throw it out, and draw it backward. I then could completely overcome the action of the subclavius and other muscles of the shoulder, and also that of the sterno-cleido-mastoid by tension upon the pectoralis major, fixing the scapula and firmly holding the fragments in apposition without at any time interfering with local circulation. This is what is desired from any splint for this fracture.

Case II.—*Transverse or short oblique fracture of the clavicle, near the outer edge of middle third.*—Kate B——, aged eighteen months, on December 10, 1879, was sent to me from the eye class by Dr. Carey, of the Demilt Dispensary. She was suffering from fracture of the clavicle. The patient had fallen from the bed and struck upon the left shoulder. She cried somewhat, but as she had at the time a deep ulcer from vaccination upon the arm of the injured shoulder, the mother had thought nothing of the accident until she had noticed a black and blue spot over the clavicle. On examination I discovered a transverse or short oblique fracture near the outer third of the clavicle, upon the same side of the body as the ulcer from vaccination. To apply either the Sayre adhesive plaster splint or the axillary wedge splint was out of the question. Hence, as was suggested to me by the article of Dr. Moore, of Rochester, in relation to the use of a shawl for holding up the shoulder, I improvised a splint. I used a scarf of unbleached cotton, six inches wide by four yards long, and made a clove hitch around the forearm, near the elbow, which was well padded. I was enabled, by drawing the elbow backward, upward, and inward, to throw the shoulder outward and upward, and draw it backward. I passed the two ends of the scarf around the uninjured shoulder and fastened it with a safety pin, bringing the loose ends across the uninjured side of the shoulder, to form a hand-sling. I was thus enabled to completely readjust the fracture and keep the broken fragments in apposition. The patient wore the splint for three weeks without complaint or any evidence of injury to the arm. At the end of that time I removed it, and found the fragments firmly united, without deformity.

In some of the following cases I used Sayre's splint, in others my own. The results in every case of using my splint, whether for oblique or transverse fracture, were equally as good as where Professor Sayre's splint was used, and with no discomfort from confining the forearm across the chest, and without the excoriation and superficial ulceration so apt to follow the use of the adhesive plaster splint, to say nothing of its want of cleanliness and danger of slipping due to the perspiration.

After a fair trial of my scarf splint on the more severe fractures of the clavicle, where the obliquity was downward and inward through the great convexity of the bone, I abandoned all other splints and confined myself to the use of my scarf splint, until I had made one more satisfactory in obtaining a fixation of the fragments with the elbow in the same position.

Fig. 2.

It is for this fracture, oblique, downward, and inward, and through the great convexity of the bone, that I claim for my new splint for fracture of the clavicle all the advantages of any other, as well as some advantages that no other splints have.

This splint is very simple, easily made, and not expensive. It is a padded gauntlet-shaped piece of leather, laced to fit the forearm, running on either side back of the

bend of the elbow. To this part is attached a strap and buckle. A padded collar with strap, buckle, and ring is fitted to the uninjured shoulder. Through this ring the strap from the elbow piece passes, and by tightly drawing this strap the arm of the injured shoulder is under sufficient control to bring the fragments into perfect apposition. A sling is made to pass from the ring of the collar on the uninjured side of the neck for the hand of the injured side.

CASE LIX.—*Long oblique fracture of middle third of clavicle; treated by backward position of elbow, and cured without deformity.*—John M——, aged seven years, in April, 1884, was brought to the dispensary by his mother, who informed me that her little boy, while climbing over a fence the day before, fell eight or ten feet headlong to the ground. Since then he had been unable to use his left arm. It hung like a dead weight by his side, the shoulder having dropped downward, forward, and inward to a very remarkable degree. The arm rotated, as it were, around in front of the chest. Examination showed a long oblique fracture near the inner edge of the middle third of clavicle, the obliquity running from above downward, inward, and backward. The patient was thin in flesh, and the line of obliquity was readily mapped out. The application of my scarf bandage splint did not seem quite satisfactory for holding the fragments in perfect apposition, as the adjustment is not so easily made as with my gauntlet and collar splint. By the application of this splint the broken fragments were held in apposition for three weeks, when I removed the splint. I found the broken bone firmly united, without any deformity or perceptible shortening of the clavicle.

CASE LXXXIII.—*Long oblique fracture of clavicle at inner edge of the middle third; obliquity running from above downward and inward.*—John F——, aged thirty-nine years, in January, 1884, came to the dispensary for advice in relation to a fracture of his right collar-bone, received three or four days before. He informed me that, while at work in a lumber yard, he and another workman were carrying a long, heavy piece of lumber; that the other man, who was in front of him, fell, dropping his end to the ground. The force of the plank's fall was communicated to Mr. F.'s shoulder, upon which rested the other end of the plank. The arm of the injured shoulder dropped by his side, and his end of the plank fell to the ground. Two days after he went to a college clinic, where a Sayre adhesive plaster splint was applied, and over this was placed a Velpeau bandage. When he presented himself at the dispensary he also complained of numbness in his hand and arm, as well as pain. I removed the bandage and found the splint in proper position for fracture of the clavicle. On examining the injury I found it to be a long, oblique fracture of the middle of the clavicle, the obliquity running from above downward and inward. The fragments were over-riding each other, and their long axes crossing like the letter X. They presented sharp points to the skin at two different places, so that the fragments were far from being apposed in their natural position. I removed the Sayre splint and applied my splint, drawing the elbow backward and inward, as in Case LIX. With the elbow in this position I was able to entirely overcome the deformity of the fragments, bringing them into apposition and holding them there. At the end of three weeks firm union had taken place. The splint was worn for a week longer, and I removed it and discharged the patient cured, with little or no deformity.

CASE C.—*Long oblique fracture of the middle of the clavicle cured without deformity.*—Jesse F——, aged ten years, was brought to the Demilt Dispensary in September, 1885, by his mother, for treatment of an injury to the right shoulder. The patient informed me that while playing on the sidewalk, the day before, a boy pushed him down, the outer edge of his shoulder striking against a stone step, since which time he was unable to use his arm. The arm hung helpless by his side with the hand and forearm in a state of pronation in front, the shoulder considerably lower, and a shortening of the clavicular line as compared with the uninjured side. Examination showed that the injury sustained was that of a long oblique fracture near the inner edge of the middle third of the clavicle. The second day following the injury I applied my splint for fracture of the clavicle. With it I was enabled to bring the fragments in apposition and hold them firmly until consolidation took place. The splint was worn with little or no discomfort for three weeks. The result, a cure without deformity.

Fractures of the condyles of the humerus.—It is admitted that injury to, or fracture of, the elbow is a serious matter, and the result thereof is largely dependent upon appropriate local treatment and care. But when the line of fracture of either condyle of the humerus runs into the joint it is doubly serious, and has thoroughly tested the ingenuity and skill of our profession, not a few of whom have been prosecuted because of a resultant stiffened joint or the so-called gunstock deformity remaining after treatment was discontinued. This fracture is generally caused by direct violence with much injury to the soft parts; hence, it is of special importance in treating it to use means that will most effectually promote the absorption of the resulting inflammatory products in and around the joint, as well as the speedy coaptation of the fragments and the holding of them firmly in apposition.

My experience in treating injuries of the elbow-joint, whether fracture obtained or not, has taught me that prompt and vigorous treatment, to combat local inflammation with effusion in and around the joint, and appropriate treatment for its reabsorption, is our only safety from false anchylosis or stiffened joint, so commonly resulting from these injuries, and so annoying to the surgeon as well as painful to the patient.

The splints generally used are the posterior, anterior, and the internal lateral angular, with or without movable joints, and each one is recommended by equally good authorities. Each has advantages and disadvantages, but, as Dr. Alis, of Philadelphia, states, none can be firmly enough applied to fix the joint without interfering with the perfect coaptation of the fragments; hence the loss of the so-called carrying point, besides the interference with local applications, which are so important in the early as well as the later treatment of these injuries.

Dr. Alis recommends semi-extension of the arm with a simple splint of flour paste or strips of adhesive plaster. Here, again, local treatment is obstructed, and I consider flour paste or adhesive plaster insufficient to hold the fragments in apposition, especially where the line of fracture is through the external condyle into the joint. At least it has proved so in my hands.

In fractures of the external condyle I have preferred the internal lateral splint, with the forearm in a state of semi-extension and the hand in a state of supination.

In cases of separation of the epiphysis I have given preference to the long anterior leather splint, extending from the shoulder to the hand and applied with the forearm in extension, then flexed to a right angle. With all of these fractures, and especially the so-called T-fracture, none of the splints in common use gave me entire satisfaction in preserving the lateral angle of the arm, so essential in retaining the carrying point and preventing the gunstock deformity—a deformity that seriously lessens the ability to use the limb for any work, especially carrying a weight by the side, to say nothing of the special distress the deformity causes to women.

CASE XII.—*Fracture of the external condyle of the humerus; treated with the internal lateral angular splint, resulting in loss of the "carrying point" with gunstock deformity.*—Geo. H——, aged twenty-three years, in June, 1880, came to the dispensary complaining of a painful injury to his right elbow. Two days before he had been knocked down by a rapidly moving express wagon. He thought the horse had stepped on his arm. Examination showed that much injury had

been done to the soft parts. Swelling was very great, and the skin was blackened from extravasation of blood on the outside of the lower end of humerus. The fragment of the condyle was drawn down, so that the lateral angle of the arm was reversed. By flexing the forearm and restoring the external lateral angle crepitation was readily obtained. The patient was confined to his bed for the next two days, and evaporating lotions, alternated with hot poultices, continually applied. It was impossible to keep the patient in bed longer, the swelling having greatly subsided. The natural contour of the arm was restored, and the broken fragments were nicely coaptated. The forearm was flexed to nearly a right angle, causing but little pain, and dressed with an internal lateral splint, with an opening for internal condyle. The patient was seen every second day at the dispensary for the next ten days, when the splint was removed and re-applied, and passive motion commenced on the tenth day. Although but little movement of the forearm could be made without causing severe pain, by the daily application of hot poultices to the elbow, at the end of four weeks from the first removal of the splint, sufficient extension of the forearm could be made to show that the external later angle of the arm, as well as the "carrying point," was lost. Patient continued to visit the dispensary, irregularly, for five or six months, but was never able to fully extend the forearm.

Case XIII.—*Fracture of internal epicondyle; treated by position without a splint, and cured at the end of four weeks without any stiffness of the joint.*—John E——, aged fourteen years, in June, 1880, came to the dispensary for advice in relation to a severe injury he had received to his left elbow. He informed me that while leaving the school-room a few hours before, he was shoved by another boy and fell, striking his elbow against the edge of a stone step. Examination showed a swelling on the inside of the elbow-joint, with a slight abrasion under the epicondyle. By extension and supination of the forearm, with my fingers pressed against the condyle, crepitus was readily felt. A further examination showed that the epicondyle was broken off and slightly drawn downward; there was no other deformity, comparing the injured with the uninjured arm, and my diagnosis was a simple fracture of the epicondyle. I sent the patient home and had him confined to bed, the arm resting upon a pillow, flexed and pronated in the most comfortable position to him, and ordered cold applications to be kept to the elbow for forty-eight hours. On the third day following I called at the house of the patient, and although cold applications had been faithfully applied, I found the elbow and forearm enormously swollen, and a large spot over the internal condyle, red and hot to the touch. The patient complained of a good deal of pain whenever the arm was moved. Tongue furred; temperature in the axilla, 101.5 degrees. I prescribed a mild cathartic, to be followed by a few doses of liquor ammonia acetatis, and locally a lotion of lead and opium, over which hot poultices of flaxseed-meal to be changed every two hours. On the second day following I called to see the patient, and found him much improved. The swelling had noticeably subsided, and the redness had quite disappeared. I now ordered an evaporating lotion to be applied to the swollen joint, and alternated with hot poultices, the patient to be kept in bed.

This plan of treatment was followed up for ten days, when I commenced passive motion, moving the joint but little at first, and increasing the degree of flexion and extension each day, and continuing the local treatment as well, until, at the end of four weeks, I discharged the patient cured, with perfect use of the joint. There was no deformity, no swelling around the joint, and full extension and flexion existed without pain or stiffness of the joint.

Case LVI.—*Fracture of lower end of humerus; treated with a long anterior leather splint.*—Edward G——, aged six years, was brought by his mother to the dispensary, in March, 1882, for advice. She informed me that while the children were out playing upon a pile of boards the day before, her little boy was thrown off, some boards falling upon him. He was carried into the house, and when his left arm was moved he cried out with pain. The arm, at the elbow, was very much swollen and black and blue to a considerable extent. It hung by the side, with the forearm extended, and midway between pronation and supination. There was very little pain, except when attempt was made to flex or rotate the forearm, and then it was very great. I put the little patient under ether, and carefully made an examination. On manipulation of the elbow, crepitus was readily obtained. The fracture was through both condyles, extending into the joint. The lower fragments were pulled backward; otherwise the position of the arm appeared normal. I had the little sufferer confined to bed,

Fig. 3.

with the arm resting upon a pillow, and treated with evaporating lotions, alternated with hot applications, for the next three days. Four days after the injury, the swelling having very much subsided, the fragments were more easily made out, confirming my former diagnosis. I now applied a long anterior leather splint, extending from the shoulder to the wrist, and held in place by adhesive plaster; then gently flexing the forearm, I was able to bring the broken fragments into natural position. A roller bandage was now applied over the splint from hand to shoulder. The splint was worn for four weeks, but was removed every three or four days to permit examination of the position of the broken fragments. At the end of three weeks passive motion was commenced. The splint was left off, permanently, at the end of four weeks. Passive motion continued daily until the end of two months, when I discharged the patient cured, with full extension and flexion of the forearm, but with some gunstock deformity, the external fragment having been pulled downward by the application of the roller bandage, holding the splint in place with the forearm flexed.

A varied experience, full of disappointments, in the use of the known splints for the more severe fractures of

the condyles, set me to work to make a splint with the following requisites :

1st. To hold the fragments in apposition.

2d. To allow the forearm to be flexed or extended, pronated or supinated, with fixation at any point.

3d. To lengthen or lessen the external lateral angle of the arm with fixation.

4th. To leave the entire elbow-joint exposed for local treatment, during the whole time of wearing the splint, without disturbing it.

The result of this work was a splint that my practice has proved to most happily meet every requisite mentioned.

Fig. 4.

Case LXXI.—T-*fracture of both condyles of lower end of humerus ; treated by my elbow splint, and cured without deformity and with perfect use of elbow-joint.*—William M——, aged eight years, in January, 1883, was brought to the dispensary by his mother. He was suffering intense pain from an injury to his right elbow-joint received the day before. His mother informed me that he had been knocked down by a horse and express wagon, falling forward on his face. The wheel of the wagon passed over his elbow. When I first saw the patient at the dispensary there was very much swelling about the joint, and the pain was so great that it was impossible to make out the extent of the injury without administering ether, which I did. The examination showed that both condyles were broken through into the joint, and could be moved upon themselves as well as upon the shaft of the humerus. The deformity was not great, except in the reversing of the outer lateral angle of the arm. The elbow was drawn somewhat backward, with the fragments tilted forward, resembling a partial dislocation of the forearm backward. I applied my elbow splint, bringing the arm into semi-extension and restoring the natural lateral angle of the arm, with the hand midway between pronation and supination. By passing a roller bandage around the rods of my splint and under the lower part of the arm and elbow, I was enabled to form a cradle for resting this part of the arm and for holding the fragments more firmly in position. I now sent the patient home and had him confined to bed with his arm resting upon a pillow. Made local applications of hot poultices, alternating with evaporating lotions. There was a considerable elevation of temperature, with coated tongue, etc. Gave a mild calomel and jalap purge, and ordered a milk diet. On the second day following I visited the patient at his home and found him in a much improved condition. The swelling around the elbow-joint had greatly subsided, and the pain was much lessened. I could now ascertain the extent of the injury, which confirmed my former diagnosis. The same treatment was continued for three or four days longer, when I commenced flexion of the forearm. At the end of ten days I flexed the forearm to nearly a right angle with the arm, not, however, without causing some pain. With the forearm flexed and midway between pronation and supination, I fixed my splint, which was held with a sling from the neck, and allowed the patient to leave the bed and take exercise out of doors. At the end of two weeks passive motion was commenced and kept up daily. The arm was held alternately by my splint at the fullest point of extension and of flexion, as seemed most adapted to overcome the stiffness of the joint. Thus the splint was of much value in preserving the natural contour of the arm, as well as in holding the forearm fixed at the farthest point gained in either flexion or extension, until I again saw the patient. At the end of two months I removed the splint altogether. The forearm could be flexed and extended to a degree almost equal with the uninjured arm. Hot poultices were applied to the elbow at intervals of two or three days during this period, and I consider their application a great factor in the restoration of the mobility of the injured joint. I saw the patient for the last time at the dispensary three months after the injury. He had the power of full extension and flexion of the forearm, with no loss of the so-called "carrying point," and with no "gun-stock" deformity.

My splint is made with two rods of untempered steel, extending from the upper part of the arm to the wrist, with a ball and socket joint at the elbow, and screws for fixation ; the lower ends pass into a sheath-screw on either side of the wrist ; the upper ends pass through two iron posts set in tin and made fast to the arm by plaster-of-Paris bandages, the rods being made firm in the posts by thumb-screws. On each side of the wrist is a post through which the sheath-screw passes, and made fast to the wrist in the same manner as the upper parts, and fastened with fixation-screws. By moving the sheath-screws the lateral angle of the arm may be contracted or widened as needed, thus overcoming any tendency to loss of the carrying point (or gunstock deformity). A turn of the fixation-screws at the elbow and wrist will allow the forearm to be flexed, extended, pronated, supinated, and fixed at any desired point without other interference with the splint.

Passive Motion.—Recognized authorities, of like high standing, differ materially as to the time when passive motion should be commenced.

While some advise commencing passive motion within a week of the injury, others say that under no circumstances should it be commenced before three to five weeks. My opinion is that passive motion should be commenced in each case according to the extent of injury to the soft parts, and our ability to hold in check and reduce the inflammation following the injury. Thus, while passive motion might be wisely commenced within a week of the injury in one case, in another it would be better surgery not to commence for three or four weeks.

Colles' Fracture.—Not having as yet treated a sufficient number of Colles' fractures by my new extension splint to draw conclusions satisfactory to myself, I will leave the discussion of its application to these fractures for a future paper.

I will briefly say, however, that whether the fracture be transverse near the carpal articulation, with splintering of the lower fragment, or a long oblique higher up, the treatment is necessarily the same ; that is, we make extension of the hand, drawing it well toward the ulnar side, and the deformity is reduced. The application of any splint in common use is to retain the fragments in their natural position by forcible compression, and the daily removal of the splint to renew extension if we would secure repair of the fracture without deformity. I have undertaken to do this by making the hand and forearm the points of resistance to overcome the natural tendency to a shortening of the radius, which tendency is, in my opinion, so powerful, so constant and vigorous in action, that it is the cause, more than any other, of the unsightly convexity over the head of the ulna. I cannot close this paper without protesting against allowing any splint whatever being kept without removal on a Colles fracture for two or three weeks at a time, or even three days. My plan has been to remove the dressing for examination of the injury every second day, until consolida-

tion of the fragments is obtained. To support this protest I will read you Case XCIX.

CASE XCIX. "*Colles' fracture;" treated by permanent splint; deformity and a crippled hand resulting therefrom.*—Mrs. G——, aged sixty-nine years, called at my office in October, 1884, to consult me in relation to a stiffness of her left hand and wrist accompanied by extreme pain. Patient gave me the following history: Three months previous, while descending the stairs, and when within three or four steps of the bottom, her heel caught on the edge of the step, throwing her forward to the floor. She fell on her left hand outstretched in front of her. A physician was called in to attend her within an hour after the injury. He said it was a "Colles' fracture," applied temporary dressing, and called the following day in company with a surgeon. After examining the fracture together a splint was applied, and left in position for two weeks, then removed and a plaster-of-Paris splint was put on, leaving it in position for six weeks longer. The result of this treatment, in this case, is a deformed wrist and crippled hand.

But, after all, this cast (cast shown) not only makes a stronger and more eloquent protest than can any words of mine, but also makes an appeal to every surgeon faithful to his human work.

OF THE LIABILITY OF PHYSICIANS FOR REPORTING, OR FAILING TO REPORT, TO THE BOARD OF HEALTH CASES OF INFECTIOUS OR CONTAGIOUS DISEASE.

BY W. A. PURRINGTON, ESQ.,

NEW YORK.

ALL liability of a physician, in legal contemplation, must arise from a breach of duty owing either to the patient, toward whom he stands in a private contractual relation, or to the general public, which requires certain offices at his hands. Where the duty is founded in contract no cause of action will accrue from its breach in favor of any one not in some way connected with the contractual relation. But if the breach be of a duty existing independently of contract, then any one injured by it may have his action for damages.

No physician is under compulsion to establish this private relation by accepting any particular person as his patient; but, having established it, he owes to that patient the duty of treating his case with ordinary skill, knowledge, and care, even though the services be rendered gratuitously. What ordinary skill and knowledge are in any particular case is a question of fact for the jury. The rule of law seems fairly settled that, generally speaking, by ordinary skill, etc., is to be understood that degree of professional attainment possessed by the average practitioner in such communities as that in which defendant practises. A specialist is held to greater skill in his specialty than a general practitioner would be, the degree of experience, the facilities for study, and the pretensions of the physician are all factors determining what in his case is ordinary skill.

The first rule governing the liability of a physician to his patient for negligence being that he is expected to exercise ordinary skill and knowledge in the case, it is limited by a second principle, which is that there is no liability for any damages except those resulting probably and proximately from the breach of duty. Negligence alone will not create a cause of action, nor will an injury which is only remotely due to the negligence. "It were infinite," said Lord Bacon, "for the law to judge the cause of causes and their impulsion one of another, therefore it contenteth itself with the immediate cause and judgeth of acts by that without looking to any further degree." But simple as this rule may seem at first glance, it often becomes a question of "Scotch metapheesics" to tell whether or not the damages complained of are due directly to the breach of duty, or have been brought on or augmented by acts of the patient or other causes. In such cases, the evidence as to facts being conflicting, the question is left to the jury. But where there is no evidence going to show that the damages resulted from the negligence, the question is one of law for the court. In a late decision of the Supreme Court of the United States, since followed by our Court of Appeals, a more scientific test of legal causation was given than is usually found in the cases. It was there said:

"The question always is, Was there an unbroken connection between the wrongful act and the injury, a continuous operation? Did the facts constitute a continuous succession of events, so linked together as to make a natural whole, or was there some new and independent cause intervening between the wrong and the injury?" If any break occurs in the continuity of events, and a new factor, especially if it be an intelligent cause, comes in to determine the result, the first ceases to be the proximate cause of the event. Thus if A set B's leg negligently, yet direct him to keep his bed and not move the limb, and B, disobediently trying to use the leg, injures it so that the damage from the disobedience cannot be distinguished from that due to the negligence, B can have no action against A. So it has been held, that if I throw a lighted squib at A, who instinctively throws it toward B, I am liable to B for any damage from the explosion; for it is as if the squib had rebounded, A not having acted otherwise than mechanically. But if I sell to an infant gunpowder, which he gives his mother to care for, and she subsequently gives him some to play with, her interposition as an independent cause frees me from the liability for damages from an explosion, which I would have incurred had the explosion taken place while the powder was originally in the child's possession. And so in actions for slander, of which the gist is malice: if special damages be claimed, they must be shown to have resulted from the original utterance and not from the repetition by a third person of the slanderous words.

Having thus seen that toward the patient a physician is liable only for the proximate and probable results of his failure to use ordinary skill, knowledge, and care in the case, we come to the question of his liability where he is commanded by a statute to do, or forbear from doing, a particular thing; such, for instance, as the reporting of cases of contagious disease to the health authorities.

Here three principles are to be borne in mind. First, no one can be held liable in damages for strictly obeying the law. Second, the law does not excuse negligence; and, if its mandate be negligently carried out, an action will lie in favor of one suffering by its careless execution. Third, if a public statute be disobeyed, any one suffering injury from such disobedience as a proximate cause shall have his action for damages.

Suppose, now, the case in New York City of a physician, A, called in to see B, whom he suspects to be suffering from a contagious disease, *e.g.*, Asiatic cholera. A has a double duty. First, he owes to B, while under his charge, ordinary care and skill. Second, he owes to the public a statutory duty prescribed in Section 608 of the Consolidation Act, which provides that every practising physician in said city shall "report in writing to said board (*i.e.*, the Board of Health) every patient he shall have laboring under any pestilential, contagious, or infectious disease, and within twenty-four hours after he shall ascertain, or suspect the nature of the disease." He is required to report, not his beliefs, not his final diagnosis only, but his reasonable suspicion. Section 131 of the Sanitary Code, which was in force at the time of enactment, and was made binding by Section 557 of said act, ordains, "That every physician shall report to the Sanitary Bureau, in writing, every person having a contagious disease (and the state of his or her disease, and his or her place of dwelling, and name, if known) which such physician has prescribed for or attended for the first time since having such a contagious disease,

during any part of the preceding twenty-four hours; *but not more than two reports shall be required in one week concerning the same person;* but every attending or practising physician thereat must, at his peril, see that such report is or has been made by some attending physician." This, then, is A's public duty, to report in writing to the health officers cases of contagious diseases within twenty-four hours after he *suspects* their nature, and to see that semi-weekly reports are thereafter made. What is his liability for so doing? Section 559 of said act provides that, "No member, officer or agent of said Board of Health, and no person (but only the board itself) shall be sued or held to liability for any act done or omitted by either person aforesaid (in good faith and with ordinary discretion) on behalf of, or under said board, or pursuant to its regulations, ordinances, or health laws." A, therefore, being a person acting pursuant to the health laws is, by the statute, and even without the statute, by common law, exempt from any liability except such as is due to his own bad faith or lack of ordinary discretion. Let us now assume that through careless diagnosis A reports B, whom he finds suffering pain, to have the Asiatic cholera, whereas he in fact has gout. Here he has failed in ordinary discretion, has been negligent, and the jury are entitled to pass upon that fact. What is the measure of damages which B can recover? Evidently all the injury resulting proximately from A's report, that is to say, injury which has no independent cause other than that report; this proximate result can only be the visit of the health officer and such consequences as may flow from that visit, entirely distinct and apart from the acts of the officer, who is himself an independent cause so far as the results of whatever action he may take are concerned. Thus, if by reason of that visit B suffers inconvenience, and loses the custom of the neighbors who, perceiving the health officer entering his house, shun B's place of business, it would seem that this damage, which must always be nominal and difficult of proof, may be probably considered a proximate result of A's negligent report. But suppose the health officer, on his own examination and diagnosis, causes the removal of B to the hospital, for this act and its results A cannot be held liable, any more than the vendor of gunpowder abovementioned was held liable for the explosion. Such removal is not a proximate or probable result of the report. There is no statute or ordinance commanding that the infecters shall be taken from their homes, nor is it understood to be the custom of the health authorities in all cases to make such removal.

Certain contagious or pestilential diseases, such as Asiatic cholera, yellow fever, and that California bugbear, leprosy—if it be contagious—are so rare that many physicians in general practice may never have seen a case of any one of them; the same is true, to a less extent perhaps, of small-pox. Such practitioners may have the general knowledge of these diseases belonging to educated men of their profession, and yet be as unable to form a true diagnosis of them within twenty-four hours as a lawyer in general practice to give an off-hand opinion on a difficult question of patent law or criminal pleading. Therefore the statute contemplates that physicians may report their suspicions—which of course must be based on reasonable grounds—to the health authorities, who in such matters are—in legal contemplation at all events—experts. Those authorities decide what shall be done with the patient. The section of the Sanitary Code above italicized, and several provisions of the Consolidation Act, contemplate leaving the patient in the physician's charge with provision for semi-weekly reports of the case. To show how illogical is the assumption that A is liable for the health officer's act in removing B, it is only necessary to reverse the hypothesis. Suppose B's malady to be in fact yellow fever, but that the health officer, concluding it to be gout, leaves the patient undisturbed, and that A withdraws from the case, leaving another physician in charge. Is A to be held liable on account of his error in diagnosis for the act of the health officer in leaving a case of contagious disease unguarded, or for any acts of the physician in charge? Certainly not, and yet that is the logical outcome of the theory that he is responsible for the removal in the first hypothesis, which is thus refuted by a *reductio ad absurdum*.

Our argument so far, if its reasoning be cogent and its statements of law sound, demonstrates: First, that no physician who, in good faith and with ordinary discretion, reports in writing to the Sanitary Bureau that he suspects a particular patient to have a contagious disease, can be held to any liability in damages for so reporting. Second, that even if his diagnosis be negligent, or not made with the requisite skill, the measure of the damages for which he can be held liable will be whatever injury *may be proved* to have resulted from his report as a proximate cause; this, it seems, can only be the nominal damage incident to the fact that a visit has been made to the patient by a health officer, but not the damage incident to that officer's acts. It may be concluded safely, therefore, that the risk incurred by so reporting is practically too small to be much considered.

But assume that, rather than take this trifling risk of litigation, A should prefer to conceal the fact that his patient B has a contagious disease rather than to report it. In that event, having violated the statute, A is liable not only to its penalties, but in damages also to every one who may prove himself to have sustained injury directly from A's breach of duty. In short, the liability is increased in a tenfold, or even greater, degree.

No man is insured against vexatious litigation. The most innocent and the wisest may be proceeded against with little color of right. "There be three things," said the wise king, "which are too wonderful for me, yea, four which I know not. The way of an eagle in the air; the way of a serpent upon a rock; the way of a ship in the midst of the sea; and the way of a man with a maid." He would add, if he lived to-day, "the way of a petit jury with a verdict." But it would seem that if there is one man who is insured against litigation on account of his act, or is reasonably certain, if action be commenced, either to win his cause or at worst suffer a verdict for only nominal damages, it is the physician who reports cases of contagious disease according to law. Small verdicts to plaintiffs do not foster a desire to institute such actions. And as a practical illustration of this immunity it is to be remarked that although for fifty-seven years we have had a statute requiring such reports, there is not one case reported in the digests of an action brought for this cause.

THE HYPODERMIC INJECTION OF OIL.—A correspondent of the *British Medical Journal* writes: "It appears that some success has been met with in America, in injecting various oils for different purposes; and, among other applications of the method, it has been used in cases of gastric ulcer, in order to supply nourishment. In a case of this sort under my care, which has made very little progress for many weeks under ordinary treatment, and where emaciation is becoming alarming, I have tried hypodermic injection of oil; but the operation causes much pain, and is followed by very painful cutaneous inflammation, so that I have been forced to give up the attempt. I need not say that every step was taken to insure success, the oil used being the purest cod-liver oil, and the syringe previously cleaned in hot water. The oil was injected into the subcutaneous areolar tissue. I shall be glad to hear something of the experience of those who have tried this method of feeding, as it seems a matter of great importance. My patient is daily losing ground under careful rectal feeding, and her stomach can tolerate nothing but a few drops of milk at long intervals. If subcutaneous feeding can be carried out, her life, like that of many others, may be saved. Would deep injection involve danger of oil-embolism? Would it be likely to cause less pain?"

COINCIDENT FRACTURE AND DISLOCATION OF THE STERNUM BY INDIRECT FORCE.

By J. P. TUTTLE, A.M., M.D.,

NEW YORK.

FRACTURE or dislocation of the sternum by indirect force is an injury of such rare occurrence as to render the following case, in which the two are coincident, almost, if not entirely, unique.

On September 20, 1884, J. B——, aged thirty-four, a stout, compactly-built man, dived from a post about six feet high into the surf, where the water was shallower than he thought. He struck forcibly against the sandy bottom, he says, on his head; but there was no proof of this—not even sand in his hair. He was shocked for the moment, but gained his footing, walked ashore, and to his house, about a hundred yards distant. I saw him shortly afterward, in company with Dr. C. Jay Seltzer, of Philadelphia, when he complained of pain in his "neck, breast, and shoulders." Movement of any kind in the arms or head was very painful, but no lesion of the spinal column could be found. An examination of the chest showed plainly a separation of the manubrium from the gladiolus, the latter overlapping the former.

In attempting to reduce the luxation, by placing a knee between the scapulæ and drawing the shoulders forcibly backward, at the same time pressing upon the upper end of the gladiolus, we observed distinct bony crepitus, and found it to proceed from a fracture of the gladiolus about one and three-quarter inches below the luxation.

Later, the patient was placed on his back with a large, hard pillow underneath the shoulders, with head and pelvis lower. By this means the location was completely reduced, and pressure on the upper end of the gladiolus showed both crepitus and slight deformity at point of fracture below, which Dr. Seltzer, and Dr. Phillips, of New York, both verified.

All that the patient complained of then was pains in the neck and breast. Those in the neck were evidently muscular, as they were not increased by pressure on the head or counter-strokes on the soles of the feet, and were increased by pressure or handling of the muscles of the neck.

The patient progressed with very few disturbances, the temperature rising at one time to 100.5°, and in four weeks was completely recovered, with very slight deformity at the point of dislocation, and a small amount of callus about the point of fracture.

The case is of interest on the following accounts:

First, there was concomitant fracture and dislocation of the two portions of the bone. Bony union had evidently not taken place between the manubrium and gladiolus.

Second, there was no other accompanying injury. The pains in the neck and shoulders were due to muscular strain, and, as will be shown further on, were produced by the same force that caused the main injury.

Dr. Hamilton reports a case, in his admirable work on fractures, in which this dual injury existed, but was accompanied by compound comminuted fracture of right leg, fracture of the necks of the first four ribs on each side, dislocation of sternum from cartilages of both second ribs, dislocation of left third cartilage from its rib, and paralysis of the bladder. The patient lived three days.[1] Dr. Watts, Jr., reports a somewhat similar case, with almost as many accompanying injuries, in which death occurred much sooner, and in which there was strong evidence of spinal concussion, at least.[2] Several cases of fracture of the sternum by indirect force are reported by Truehaart,[3] Levis,[4] Butterham,[5] and Lane,[6] but in none of them was the double injury found.

[5] Lancet, London, March, 1884.
[6] British Medical Journal, March, 1884.

Third, the injury was produced by indirect force, from a headlong fall. This is a point to which I would call special attention, as a satisfactory explanation of the production of such injuries has not yet been given. It is very evident how a patient falling across a bar or other object, on his back, may fracture or separate the bones of the sternum by forcible extension of the abdominal and sterno-cleido-mastoid muscles. Such cases are reported by various observers.[1] But how the force of a fall upon the head can be transmitted to the sternum without fracture, dislocation, or some injury to the cervical vertebræ, is incomprehensible to me.

Dr. Johnson reports a case of fracture of the sternum which the patient says was produced by falling on his head from a hay-cart.[2] In the cases of Hamilton and Watts mentioned above, the force is also supposed to have been exerted first on the head. But in none of these cases is there any injury of the head, not even a contusion, mentioned. It seems impossible for the injury to be thus produced without some such accompanying lesion, and either rupture of the spinous ligaments or, at least, concussion ofthe spinal cord.

The natural and well-known fact that men falling headforemost extend their hands unconsciously in order to catch the force on them, and thus save their heads, and the almost invariableness with which this position is assumed by divers, suggested that my own case, at least, and perhaps some others, might have been produced by falling upon the outstretched hands, and the transmission of the force thence through the clavicles and first ribs to the upper portion of the sternum.

The force thus expended upon the manubrium is a downward (with reference to the body) and backward force, while that exerted upon the gladiolus by the momentum of the body and abdominal viscera, through the diaphragm and lower ribs, is an upward and forward one. These two forces acting at variance, it is not difficult to see how fracture of the sternum may be produced; and if it occur below the juncture of the gladiolus and manubrium, which it does not in most instances, how a consequent dislocation of these two bones is likely to occur; for, after the fracture, the bending backward of the upper fragment furnishes an inclined plane of resistance to the lower end of the manubrium, off of which it easily slips and thus becomes dislocated, the third and fourth ribs still forcing the top fragment of the gladiolus upward and forward. The existence and direction of these forces can be demonstrated by observing the motions of the clavicles and sternum of an acrobat when he first rises to walk on his hands; or the first may also be seen in a well-articulated skeleton.

In view of these facts it is reasonable to suppose that the above case of my own, and perhaps that of Dr. Johnson, fell upon their hands first, and only struck their heads, if they struck them at all, after the force had been expended upon the sternum and it had given way. Of course, such an injury could only occur in this way in a person with large, strong clavicles.

As to the pains in the neck and shoulders, the strain upon the muscles thereabouts, especially the sterno-cleido mastoids, and the tension upon the shoulder-joints, would easily account for these, although I may mention that Dr. Gross considers pain in the back of the neck an almost constant symptom in dislocation or fracture with displacement of the sternum, whether by direct or indirect force.[3]

The fourth point of interest in this case, doubtless the first to the patient, is his recovery: truly, not from any superior treatment, but solely because the injury was uncomplicated by more serious ones, as were the cases of the distinguished observers mentioned. I have seen him frequently a year after the injury, and slight deformity at both points of injury exists.

[1] Hamilton, loc. cit., 181. Malgaigne on Fracture, Arch. de Med., 1827; Gaz. Med., 1842. Gross-System Surgery, 964.
[2] Med. and Chir. Rev., N. S., vol. xvii., 536.
[3] Loc. cit., 962.

It may be argued that the clavicle would give way before a fracture of the sternum could be produced. But Dr. Arbuthnot Lane has shown by experiment on the cadaver that heavy blows on a padded shoulder will produce fracture of the sternum. He claims, however, that the force is transmitted, not from the clavicle to the sternum direct, but "*only* through the first and second ribs." It is easy to see some influence of the first rib, at least, but to admit the "only" is very difficult, seeing that the clavicle and sternum are more closely connected than the clavicle and first rib. Maisonneuve attributes the fracture to force transmitted through the clavicle, as does also Levis, who remarks that the simple fracture is by no means so rare as the standard works on surgery would lead one to believe.

136 West Forty-first Street.

CARDICENTESIS.

By A. H. P. LEUF, M.D.,

PATHOLOGIST TO ST. MARY'S GENERAL HOSPITAL, TO ST. MARY'S FEMALE HOSPITAL, AND TO THE HOSPITAL FOR NERVOUS AND MENTAL DISEASES, AND SECRETARY OF THE BROOKLYN PATHOLOGICAL SOCIETY, ETC.

A paper entitled "As to Cardiac Aspiration" appeared in The Medical Record of November 14, 1885. Dr. W. S. Cheesman is the author. The note calls for a reply. It is gratifying to see that the doctor's interest in the subject is unabated, for he has been in the field before opposed to the procedure. He mentions my paper on "Pulmonary Congestions and Cardiac Aspiration," that appeared in the *American Journal of the Medical Sciences* of January, 1885, and the editorial in The Medical Record of October 31, 1885, on Mr. Dacre's case of aortic aspiration, as the latest contributions to this subject. Another, however, appeared in the editorial columns of the *Journal of the American Medical Association* of April, 1885, in which the advisability of the operation is upheld in unmistakable terms.

Dr. Cheesman next reiterates his objection to cardicentesis on account of the danger of laceration of the auricular wall. To prove this he cites a case that came under his observation while interne at Bellevue. "A hypodermic needle was introduced into the space uncovered by lung" for the purpose of *pericardial* aspiration. "The syringe filled with blood, and was at once withdrawn. While being withdrawn, the needle was distinctly felt to be moved with or against the heart in its contraction." The patient died very gradually six hours after the aspiration. At the autopsy the heart was found enveloped with a blood-clot, and a quarter-inch rent was found on the right ventricular wall "in one spot between the columnæ." The heart was hypertrophied and fatty. Having seen such rents with similar after-effects in the same class of hearts and without any puncture, a doubt naturally arises in my mind whether the hæmopericardium in Dr. Cheesman's case was due to aspiration, or may not have been spontaneous. Nothing is said of a corresponding opening in the parietal pericardium, or of the site of the rent in the right ventricle with reference to the needle opening in the thoracic wall. The probability, however, is that the puncture was the cause.

It is not fair to offer this case in opposition to the operation. Surely neither Dr. Westbrook, Dr. Roberts, or myself would care to aspirate a *fatty* heart. That has never been advocated. Another important point is the fact that a hypodermic needle is a little too short to be used with safety. It should be long enough to sufficiently penetrate the heart cavity, so as to offer a minimum resistance to the cardiac movements at its point of entrance. A short needle is relatively more rigidly held in the thoracic wall, and its point more fixed and unyielding, than a long one. The normal elasticity and contractility of the heart-wall diminishes when it has undergone fatty changes. Even in Dr. Cheesman's case there probably would have been no outpouring of blood if the needle had not just happened to strike such an exceptionally thin part of the heart. Another case of accidental puncture is mentioned as having happened to a member of the visiting staff at Bellevue. No more is said about it, and so there can be no discussion on that.

Dr. Cheesman confesses himself "frightened" at a little hæmopericardium because "they mean leakage, hæmopericardium, which in some other cases may be sufficiently abundant to kill." That such may now and then occur is self-evident. But is there not a certain risk to life in almost any surgical interference? Even so simple and usually harmless a procedure as tooth-pulling has more than once resulted fatally. No one ever denied the danger of cardicentesis in all diseased conditions of the heart in which there was weakening of the walls. For these cases it is not intended, and I believe I am echoing the sentiment of all advocates of the operation in imploring the forbearance of experimenters in this class of cases. If Dr. Cheesman will limit his fears and objections to this unwarrantable, meddlesome interference, there will be unanimity.

In my former paper it is expressly stated that "the operation was designed for the relief of the heart laboring under physical difficulties, and especially without organic disease." Given a case of organic disease without weakening of the heart-walls, and we can only hope for temporary relief by aspiration, because it does not remove the cause. In a case of over-distention, however, of the right side, in an undiseased heart, with empty peripheral veins and a weak systole, permanent relief, cure, may be effected by the timely performance of this operation. I maintain that this operation, if done at all, should be performed as soon as its necessity seems assured.

The operation has recalled to consciousness and maintained in that condition a man, for a number of hours, who had been *in articulo mortis*, and was almost momentarily expected to die. The benefit of such restoration of the mind for so long a time, under innumerable readily-imagined circumstances, would be of incalculable value. The value might relate to the family, business, politics, war, science, art, etc.

I also desire to "actually" reassert that cardicentesis properly performed is simpler and less disheartening to the patient than the ordinary phlebotomy, and would maintain this assertion at length if worth so much space.

The last point in the paper under discussion is one that it would have been better not to raise. It is said, 'One other point has been made much of by Dr. Leuf (in his article above-referred to), viz., that the conception of this operation was original with Dr. Westbrook." Dr. Cheesman is guilty of rather a remarkable error in this instance. He really makes no distinction between mere sight, discovery, and device or invention. One man sees a thing, and may even handle it without putting it to any special use—he sees or experiences; another notices a special use for it—he discovers; still another, by reasoning, finds for it a special use, or, arguing from effect back to cause, detects the existence of the thing or body from the use to which it is to be applied—he devises, he invents, to discover and apply. Two men quarrel, one picks up a knife and introduces the point into the other's heart—he performs cardicentesis. This is being done now, was done centuries ago, and will be done as long hence. This is the man who merely sees or experiences. A number of professional brethren have accidentally penetrated the heart with hollow needles, much to their surprise and alarm. Of these Dr. Cheesman speaks. They are the men who simply discover, and without appreciating the value of what they observe. Dr. Benj. F. Westbrook saw certain conditions of the heart associated with others of the circulation, and reasoning from effect back to cause, devised for, invented for, and applied the unappreciated and undeveloped experience of others to this condition, and is the originator of the operation of cardicentesis. John Hunter devised a surgical method for the treatment of aneurism, and the procedure was ever after called his. So the chancre,

which he was the first to describe so well. Leverrier, of France, and Adams, of England, accomplished a similar end, but higher in degree, in the determination of a planet that must have been seen again and again by competent observers without its character being suspected. To these men justly belongs the credit they receive, and not to some other, who could, perhaps, prove that he happened to see this body before its discovery was announced. And, although Leverrier announced his discovery a couple of weeks before Adams did his, the latter deserves equal credit with the former because his methods were as independent and original. To Bunsen and Kirchoff, of Germany, also belongs the honor of having done the same class of work in painstaking search after the metallic elements rubidium and cæsium, the existence of which had been determined by *a priori* reasoning. Suppose others had handled these metals before them, could these latter dispute with Bunsen and Kirchoff the title of discoverers, when they had to learn from them that it was something hitherto unknown? Certainly not, and that is precisely the position of cardicentesis to-day, but of inferior degree, in reference to the claim I make for Dr. Westbrook, and that Dr. Cheesman makes for the other gentlemen. Dr. Cheesman has just as much right, in principle, to the credit of owning this operation as have either Roger or Hulke, for both the latter performed accidental puncture.

Dr. Westbrook was the first one to deliberately plan and perform cardicentesis. Dr. Cheesman is wrong to say I "made much" of this being "Westbrook's operation." I only desired to give full credit, and this I did. Only once in my whole paper is the expression "Westbrook's operation" to be found. It was put so inadvertently in that instance, as I am not in favor of naming operations after individuals. Cardicentesis, therefore, has been called "Westbrook's operation," because it is.

Concerning M. J. Dacre's case, in the *Bristol Medico-Chirurgical Journal*, it is proper to note that there was considerable fluid in the lungs previous to the operation, and that this was only performed when the patient was without pulse and with hardly a systolic sound. Dr. Westbrook's first case was also one with œdematous lungs. In such cases only transient relief can be hoped for. It is, however, another one added to the cases that prove cardicentesis a safe procedure when judiciously performed.

It also seems, according to Mr. Dacre's experience, that the right fourth intercostal space near the sternum is the proper place of entrance for puncture of the right auricle. This does not agree with numerous very careful and painstaking anatomical observations that were made by Dr. Westbrook, and others by myself for him, as they showed, with but two exceptions, I believe, that the right third intercostal space, close to the sternum, was the safest and most certain. The right auriculo-ventricular groove and the artery it contains usually cross the right fourth intercostal space obliquely downward and outward.

The needle should be long and made to penetrate deeply into the auricular or ventricular cavity. It should also be introduced very rapidly. The best way is for the surgeon to grasp the needle firmly at a point where, when it is in position, it would just be at the surface of the chest, and then it should be quickly plunged directly backward, so as to penetrate the auricular wall at the same time that it perforates the parietal pericardium.

There will soon appear in another journal the account of another case of cardicentesis by Dr. B. F. Westbrook. The criticism I wish to make upon it is that the malady had progressed so far that permanent reaction was hopeless. This leads me to again emphasize the necessity of operating early. Just so soon as we have a very reasonable excuse for supposing that a dangerous dilatation of the heart is inevitable, I believe it to be our duty to aspirate freely and without delay.

Another point worthy of reconsideration is the site of puncture in the chest and heart-wall. On account of the difference in thickness and contractility of the auricular and ventricular walls, it might appear safest to enter the ventricle. The base of the heart, though, is less movable than the apex, and on this account there is least strain upon the cardiac wall at the base. The question as to the relative proportion between the thickness of these walls and the mobility of the corresponding parts of the heart can only be settled by future experience.

In conclusion, I would say to Dr. Cheesman that I fear he misunderstood the tone of my call for a description of the cases he formerly alluded to, and which he tells us were those reported by Dr. Dana. No sarcasm was meant, but the questions were put honestly, and I trust the Doctor will so consider everything said in this paper. Personal feeling should be understood as excluded from all scientific discussions.

Clinical Department.

HYDROGEN PEROXIDE IN THE TREATMENT OF ULCERS AND SINUSES.

Dr. C. G. Roehr, of Milwaukee, Wis., writes that he has used peroxide of hydrogen, with excellent results, as a disinfectant and stimulant to old ulcers and sinuses. When injected into sinuses containing exuberant granulations it destroys these, leaving uninjured the healthy tissues. There is very little pain, and a rapid improvement ensues.

MELANCHOLIA.

Dr. S. A. Defoe, of Washington, N. J., writes that he has found the following to give excellent results in melancholia. ℞. Valerianates of zinc, quinine, and iron, each twenty grains, to be divided into twenty pills. One pill is to be taken three times a day before meals. The drugs should be absolutely pure. Dr. Defoe says he has tried this remedy thoroughly, and finds it a specific for the worry of nervous women and for incipient melancholia.

COCAINE IN SEA-SICKNESS.

Dr. J. B. Bissell, of this city, writes us as follows: "Cocaine has been recently recommended as a remedy in sea-sickness, particularly by a Russian physician, who claims to obtain speedy and certain relief by its use in this affection. In a voyage from New York to Charleston, S. C., made in November of this year, an excellent opportunity was afforded to ascertain the value of the drug in this regard. The time of passage was four days, the weather fair, and no storms, but a head wind lasted all the way. The experiments were made on twenty-seven persons of both sexes, and from four years of age to forty-eight. The hydrochlorate of cocaine, in doses of a twentieth and a twenty-fifth of a grain, in tablets, was given by mouth. In one set of cases the medicine was begun soon after leaving the wharf; in another set at the first symptom of nausea; in a third set not till vomiting had taken place. In the first set the dose was a twentieth of a grain, repeated every hour till two grains had been taken. In the other cases a twenty-fifth every fifteen minutes up to two grains, or, as happened in nearly every case, till the patients became so sick that they refused to continue the drug. This was usually after the fifth or sixth dose. The results from these three sets of cases were almost precisely similar. In twelve cases there was no improvement, if the treatment did not positively make the patients worse. In six cases there was certainly an increase in the severity of the symptoms. In only three of the twenty-seven cases was there apparent benefit, and this improvement was coincident with a temporary improvement of the weather. As the sea became rougher

all three relapsed, and in spite of the cocaine became very sick. The other six of the twenty-seven were at sea for the first time. One of these was not sick at all during the trip. The others, however, did not escape. I did not notice any special influence exerted by the age or sex of the person treated. Such results as the above ought to dispose of cocaine as a remedy in sea-sickness, but as these results don't advertise any one's special method of administering the drug, or any firm's special preparation, it is very likely it will continue to be used till a newer remedy comes into fashion."

WHAT WAS THE CAUSE OF DEATH?

Dr. John H. Sevier, of Brownsville, Tenn., sends us the following: "L. C——, a colored primipara, aged twenty-eight years, was admitted to the lying-in ward of the Medical College Hospital, Nashville, Tenn., in January, 1884, while I was house surgeon. She appeared to be perfectly healthy. Soon after her admission I was sent for, in the absence of the house physician, and found her in the first stage of labor. The case progressed nicely, when suddenly she became comatose, with stertorous breathing, and died in a few minutes. The visiting obstetrician was at once summoned, and he arrived promptly, but too late to save the child by Cæsarean section. There was no evidence of poison, or reason to suspect any, and it was thought that she had died of apoplexy. Post-mortem examination, however, revealed no clot in the brain, nor lesion of any organ whatever."

SCIATICA RELIEVED BY A SINGLE COCAINE INJECTION.

Dr. W. B. Menz, of Vidalia, La., writes that he was called to see a lady, fifty-five years of age, who had been a constant sufferer from sciatica for ten years. The pain was very severe, and extended along the entire length of the nerve. She had run the whole gamut of anti-neuralgic remedies, and had never obtained anything more than very transitory relief. Having with him a vial of a four per cent. solution of cocaine hydrochlorate, Dr. Menz determined to try the efficacy of a subcutaneous injection. The hypodermic needle was inserted deeply over the sciatic foramen, and about twenty drops of the solution were passed into the tissues. The pain ceased almost immediately, and during the six weeks that have since elapsed has not returned, although there has been no further treatment, and one injection only was practised. The relief given by other remedies had never been of more than from two to four hours' duration.

POPLITEAL ANEURISM—LIGATION OF THE FEMORAL ARTERY—RECOVERY.

Dr. J. B. Houston, of Malden, W. Va., reports the following case: A. H——, twenty-eight years of age, a miner, had suffered for a long time from pain in the thigh and popliteal region, most severe while he was at work and standing, and relieved only when lying down at night. After some months he noticed a small tumor in the popliteal space, about the size of a marble, soft and compressible, but does not remember that there was any pulsation perceptible in it at this time. While playing a game of base-ball one day, he felt as though "something had given way under the knee," and the pain was greater after this. The physician whom he had consulted from time to time, noticing the rapid increase in the size of the tumor, at length advised compression, using an instrument devised by himself for this purpose. The pain and œdema caused by the application of this compressor soon compelled its discontinuance. At this time the patient consulted Dr. Houston, who found an aneurism nearly filling the popliteal space and covered by tense skin, which seemed to be upon the point of ulcerating. An immediate operation was advised, and assented to by the patient. "Accordingly, on October 19th, assisted by Drs. Thomas and Tompkins, of Charleston, I proceeded to operate, exposing the artery near the entrance to Hunter's canal. After reaching the vessel without trouble, and direct pressure being found to stop all pulsation in the aneurism, I tied the artery tightly with a silk ligature, leaving one end out of the wound, which was closed by interrupted suture. The wound healed rapidly and pain in the leg ceased. Shortly after the vessel was tied I wrapped the leg in cotton batting and placed it, slightly flexed, on a pillow in the bed, and kept it at about the normal temperature with bottles of hot water under the bed-clothes, but not touching the limb. There was no œdema of the foot or leg, nor were there any symptoms of lowered vitality in the limb. The temperature of the skin was somewhat elevated for the first two days, due, I suppose, to the increased capillary circulation. On November 24th, just five weeks after operation, I pulled out the ligature, the wound having entirely closed except along the track of the ligature. My patient is walking, has no pain, and the aneurism is hard and reduced to half its size, having decreased more rapidly in the last three weeks than in the first two weeks after the operation."

CIRRHOSIS (?) OF THE LIVER IN A YOUNG CHILD.

Dr. E. Frank Marsh, of Oswego Falls, N. Y., writes: "On November 13, 1885, I was called to see a male child, aged two years and eight months. I found him suffering from marked ascites, with elevated temperature, respiration 56, and pulse 150. There was considerable jaundice, urine high colored and scanty, but no œdema of lower lids, or of feet. He took scarcely any nourishment, but drank eagerly. The mother said the child had been failing steadily for several months. Two days later, I introduced a trocar and drew off nearly two quarts of fluid. The opening did not heal for several days, and the serum continued to dribble away. The operation seemed to relieve the child, and after the removal of the effusion I could make out the liver considerably enlarged, and extremely hard. I pronounced it a case of cirrhosis of the liver. The father died of the same disease a little more than a year ago. The child continued failing till the 28th, when he died. There was no post-mortem examination. Upon investigation, I cannot find a case of cirrhosis recorded in so young a child as this, and in this case the abuse of spirituous liquors was certainly not the cause of the disease."

The Doctor's Peculiar Danger.—*The Medical Age* deals with a delicate subject in the following skilful manner: "The physician, especially if he has been favored by nature with physical attractions, is above all men subject to sexual temptations. His relations to his female *clientèle* are of that secret and confidential nature which tends to familiarity. Weak women, who are diffident and shy toward all other males, frequently conceive for their physician a passion which it would require but a slight response to convert into a crime. We apprehend there are few of our readers whom professional experience has not convinced of this frailty (which may, after all, be more or less physiological) on the part of the weaker vessel. In view of this fact it is very complimentary to the profession that there are so few scandals chargeable to it. As compared with even the clergy (the especial conservators of morals) physicians stand well in this respect. Doubtless, too, not a few of the scandals chargeable to medical men have no sufficient foundation, the peculiar relations of the doctor to his female patients laying him especially open to the schemes of the blackmailer."

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 19, 1885.

TRAINING-SCHOOLS FOR ATTENDANTS IN ASYLUMS FOR THE INSANE.

THE Buffalo State Asylum for the Insane has recently taken a most important step in the direction of securing a higher grade of qualification of attendants upon its wards. The plan, prepared by the Superintendent, Dr. Judson B. Andrews, and the First Assistant Physician, Dr. William Granger, contemplates a regular system of training attendants for their duties by a course of special instruction, didactic and clinical. The result will be to improve and elevate the standard of service in the care of the insane, and to give to the institution under their charge the benefit of a corps of attendants skilled in this special work, and who may make it a permanent occupation.

The plan of instruction is the outgrowth of a system begun by the officers of the Asylum in October, 1883, among a limited number of attendants. The benefit derived both by them and the Asylum has been such as to induce the Board to offer to all the attendants, who are found qualified, the advantages of instruction in the care and nursing of the sick and insane. From the rules adopted by the managers we gather the following facts regarding the employment, training, and pay of attendants who avail themselves of the offered facilities for advancement in education. The most desirable age for attendants, both men and women, is from twenty-one to thirty. All applicants for the position of attendants are required to be in sound health, and to furnish testimonials of good moral character and of correct habits, from at least two responsible persons. They must be of pleasant and kindly disposition, and possess such mental and educational qualifications as give promise of fitness for the work. All applicants must pass the Civil Service Examination, as required by the law of the State. After a probationary period of two months, if found capable and satisfactory, they shall, before being permanently employed, sign the agreement required of all employees. All attendants are to be instructed in the rules and regulations of the Asylum, and in the duties of their several positions. The special training of the school will be given by the Assistant Physicians, under the direction of the Superintendent, in such studies and methods as will best fit those who receive the instruction for the special work of attendants upon the insane and for nursing the sick. The course will occupy two years, and will consist of lectures and clinical instruction. The lectures will be given on the fundamental principles of physiology, and of hygiene, including ventilation, clothing, bathing, etc., with the usual directions for the care of the person, the bed, and the room of the sick. Instruction will be given upon the most commonly used remedies and their effects, upon the use of the catheter, the taking of temperatures, the administration of food, the control of hemorrhage, and the application of minor dressings. Special attention will be given to teaching the best methods of caring for the various classes of the insane—the violent, destructive, suicidal, and epileptic, as also the quiet and convalescent—with directions as to exercise, occupation, amusement, and companionship. They will be taught to meet emergencies, how and what to observe, and to make written reports upon the physical and mental condition of patients. All who join the training-school must, at the end of the first year, pass a satisfactory examination before entering on the second year's instruction. At the close of the second year, after passing the required examination, and giving satisfactory service, they will receive a certificate from the institution as well-qualified nurses and attendants upon the insane. Those who take advantage of the instruction of the school will receive, after passing the examination at the end of the first year, the women at the rate of fifteen, and the men at the rate of twenty-five dollars per month, and two weeks' vacation, annually thereafter, without deduction of pay, at a time subject to the convenience of the Asylum. After passing the examination at the close of the second year, and receiving a certificate of qualification as trained nurses and attendants, they will be paid, the women at the rate of eighteen, and the men at the rate of twenty-eight dollars per month, respectively. The trained attendants who are placed in charge of wards will be paid, the women at the rate of twenty, and the men at the rate of thirty dollars per month, respectively. The acceptance of the advanced pay attached to these propositions shall carry with it the obligation to remain in each case at least one year longer in the service of the Asylum, subject to the provisions of the agreement. For long and faithful service an increase in the pay per month may be provided in special cases. In addition to the pay, attendants receive board, lodging, washing, and medical care during temporary illness.

The practicability of a training-school in an asylum has heretofore been in doubt, but the experience of the managers of the Buffalo Asylum has fully demonstrated not only that it is practicable, but that such a school is really necessary to the highest grade of care of the insane. The members of the Resident Medical Staff, who carry out the details of instruction, are united in their expressions of satisfaction with the results of teaching. The attendants enter into their studies with great interest, and find in the school a pleasant diversion from their monotonous duties, a new field for their improvement, and the preparation for a life's occupation. Several illustrations of the value of the instruction given can now be furnished from the records of the institution. A patient was recently found at night by a trained attendant suspended from his bedstead by a handkerchief about his neck. The attendant cut him down, and began to

apply Sylvester's method of resuscitation, while an assistant pulled the tongue forcibly out of the mouth. After a few minutes the patient began to breathe, and when the physician arrived the emergency had passed. In two other cases blood-vessels have been wounded under circumstances involving great risk to life had not the attendants, in both instances, been competent to apply accurate pressure to the proper vessels.

We must conclude that the Buffalo Asylum has set a most praiseworthy example in establishing a Training School for its attendants, and that it has begun a new era in providing thoroughly qualified persons for the immediate and personal care of the insane.

THE RESULTS OF LARYNGEAL SURGERY.

THE operation of excision of the larynx was, we believe, first performed by P. H. Watson in 1866. He was followed by Billroth in 1873, and later by a number of surgeons, including Heine and Gussenbauer, of Prague; Langenbeck, Caselli, of Milan; Schmidt, of Frankfort; Foulis, of Glasgow, and others. In 1884 Hahn (*Arch. f. klin. Chir.*, xxxi., p. 171) collected the statistics of 52 operations for total excision. In 24 of these death followed in consequence of the operation. On the other hand, in 12 operations for partial removal, death followed in only 1 case.

The name of Billroth has been particularly associated with operations upon the larynx, and recently Dr. F. Salzer has collected the histories of the cases occurring in his clinic from 1870 to 1884. These include 11 of laryngeal section, 7 of partial extirpation, and 5 of total extirpation. It appears to one reading these records that nothing could be much more discouraging than Billroth's laryngeal surgery; indeed, a less noted operator would hardly dare publish so unpromising a series of cases.

In his laryngofission cases 10 patients were operated upon 11 times. Of these the wound healed in 8 cases, but in 6 there was subsequently either death or relapse; 3 cases ended fatally within eight days. The result of 8 operations for carcinoma was very unfavorable, since, out of the 8, in only 1 case was there no relapse (two years and nine months after operation).

In 7 cases of partial extirpation death speedily occurred in 3 instances. Of the 6 cases operated upon for carcinoma laryngis, a relapse occurred, and generally very speedily, in all instances but 2. These, however, had, at the time of the report, been operated upon for only two and four months respectively. In 3 cases the functional result was favorable, the patient regaining a certain amount of voice.

The 5 cases of total extirpation of the larynx is an uninterrupted record of death. The patients all had carcinoma, and all died within from one day to seven months after the operation. One patient, to be sure, recovered from the operation, and died later from a relapse; and a second recovered also from the operation, but died in five weeks from purulent pericarditis.

Out of 22 patients operated upon by Billroth, mostly for carcinoma laryngis, 19 are dead, and 2 more are extremely liable to a relapse.

Billroth's cases are much worse than those collected by Foulis. Of 26 cases of total extirpation, 14 died in consequence of the operation. Of the remaining 12, 3 died in relapse.

Still more favorable are the results obtained by Professor Thiersch, of Leipzig, reported by Dr. A. Landerer (*Deutsche-Zeitschr. f. Chir.*, xvi., 1 u. 2, p. 149, 1882). Of 4 cases of total extirpation for carcinoma laryngis, 1 died in consequence of the operation, 1 died of a relapse three months later, and 2 recovered and had no relapse (seventeen to eighteen months).

ONOMATOMANIA.

PERSONS who suffer from agonizing mental distress in their desire to recall certain names are said by MM. Charcot and Magnan to have "onomatomania," or verbal mania. An excellent illustration of this trouble is given: A young man, aged sixteen, of neurotic antecedents was suddenly taken with the following symptoms:

"While walking in the Champs-Elysées he met a gentleman whose acquaintance he had made during a journey to Rome. The young man stopped and conversed with him for some time. After they had separated he tried in vain to recall his name. Not succeeding, he tried to drop the matter, and think of something else. But the inability to recall the stranger's name pressed upon him more and more. He could not rid himself of the effort to remember it; he became depressed in spirits, his face was covered with perspiration, his hands cold, and he reached his rooms in a state of the greatest agony. After this, he frequently became subject to similar attacks of acute mental distress. To obviate it, he carried with him a memorandum book, in which he put the names of all his acquaintances, and to which he could, when in need, refer. This procured him some relief for a time, but his malady soon took a wider range, and he became possessed with an irresistible desire to know the names of all persons who passed in carriages or whom he met in railway trains. The impossibility of learning their names mortified and exasperated him, until, finally, he would go about avoiding the sight of every one, and at last retired to the seclusion of a country house."

Such is a type of an onomatomaniac. The mental and physical distress may be brought on by a failure to recall the names of persons or of things. The crisis of anxiety and pain ceases when the name is found.

MM. Charcot and Magnan state that this peculiar mental symptom occurs only in persons who have a distinct hereditary psychopathic taint. Every one can see that the symptom is only a morbid exaggeration of the very slight mental discomfort which many persons feel when they cannot recall a name which is tolerably familiar.

The disorder belongs undoubtedly among the milder types of the degenerative psychoses, and is closely allied with the disturbances known as agoraphobia, mysophobia, and *folie du doute*.

URÆMIC PARALYSIS IN THE AGED.

M. MAURICE RAYMOND in his service at the Ivry Asylum, has observed and studied a peculiar class of paralytic accidents occurring in the aged. These consist of more or less sudden attacks of hemiplegia, which may

involve the face and extremities, or only the extremities, and in which the paralysis is sometimes flaccid, sometimes accompanied with contractures. In those cases which end in death autopsy reveals no lesion in the brain, but the kidneys are uniformly found to be markedly diseased. M. Raymond divides the cases into three groups. In the first the patients are suddenly, without prodromal symptoms, attacked with hemiplegia, they become comatose, and die either immediately or after a lingering illness. Autopsy reveals neither clot nor softening. In a second class of cases the patients are suddenly taken with a hemiplegia more or less complete. If death ensues, the brain shows only evidences of œdema and some ventricular effusion.

The third class includes patients who have previously had a cerebral hemorrhage and hemiplegia. Upon this supervenes a new attack of hemiplegia, which, however, does not indicate a new hemorrhage, but rather a partial cerebral œdema and anæmia.

M. Raymond believes that these paralytic attacks in the aged are due primarily to renal disease and uræmia. Œdema and "anoxæmia," are produced by the uræmic poisoning, and M. Raymond quotes an experiment upon a dog to show that the production of partial cerebral œdema and anæmia will cause paralysis.

THE MAN WITH INTERESTING CASES.

THE young medical man who launches his (largely Peruvian) bark upon the unhealthful seas of medical practice has many discomforts, obstacles, and dangers to encounter. Not the least among the minor ills—to drop our meritorious but ancient simile—is that of the man who always has a case to describe.

Some distinguished medical philosopher has remarked that he would rather be knocked on the head at once, than be stopped on the street and told about a case. This gentleman evidently had had some painful experiences, which perhaps warped his judgment a little; for, after all, to be knocked on the head is not only disagreeable but serious, while the man with the case is a depressive force rather than a destructive one.

Every one knows him, however, this man of many cases; he meets one at the street corner, at societies, he drops in at the office. He greets his victims with a pleasant "Good-day-how-is-practice-last-night-I-was-called-to-see-a-" etc., manner, and in a moment he is in the midst of bedside details of anguishing minuteness. One listens in a dazed way, catching now and then something about "injections," "temperature," "bowels," "bladder," and similar expressions; while perhaps the speaker ends temporarily with an explanation of why he called some other gentleman in consultation.

The case-fiend penetrates every stratum of society. To tell the story of his experiences with unhealthiness, is to him a kind of erotic joy. His cook, his wife, his druggist, the poor, the rich, the sick, the well, all get a share of his case-book. He drops into a case-recital as easily as Joseffy into a sonata, or a *première danseuse* into a pirouette; his intellectual life is in the verbal revival of his pathological experiences; of these he is a word-painter, pre-Raphaelitic in detail, persistent in purpose, and exhaustless in resources.

He is seen at societies, and here he acts as a dispersive force of singular potency upon members; and respectable gentlemen of our medical profession of high standing and large practice will steal on tip-toe out of side-doors, like thieves in the night.

But it is, after all, in his private relations that the man of cases is at his best; and the question of what shall be done with him is a medico-social problem of deep interest.

For our part, we urge upon these gentlemen a prompt reform. We would assure them that in many departments of medical knowledge clinical recitals can add nothing, and that in some directions the end of clinical research has been nearly reached. This should make these more than Roman viaducts of bed-side studies very careful. They should reserve these exercises of their memories, and cultivate somewhat more their logical faculty and the powers of interpreting the meanings of things. This bedside tattle of "cases" is too often the same kind of stuff as the gossip of a ladies' dressing-room.

A DISPENSARY THAT IS NOT WANTED.

AT the recent anniversary meeting of the Presbyterian Hospital, it was announced that an Out-patient Department was contemplated "to meet the wants of the rapidly increasing population of the neighborhood."

The immediate "neighborhood" in question is mostly built up with brown-stone private residences. Farther east, in the tenement-house district, is the North-Eastern Dispensary, which treats 24,000 patients annually; and only six blocks away from the Presbyterian Hospital is the Mt. Sinai Dispensary, which gives 40,000 consultations annually. Besides these, is the Harlem Dispensary at 126th Street, and two special dispensaries on 59th and 125th Streets. There is already a total of eleven dispensaries in the Ward.

No new dispensaries are needed in this neighborhood, and, considering the present deplorable state of our medical charities, it is to be hoped that the project will be abandoned. We have already heard protests against it by physicians practising in the neighborhood.

THE NEW YORK ASSOCIATION FOR IMPROVING THE CONDITION OF THE POOR.

SOME of the objects of this Association, as set forth in its Annual Report, are: To aid in carrying out the laws relating to the health and cleanliness of the city, to elevate the health and home-life of the poor, and to secure for the tenement-house population improved conditions of living.

In carrying out these objects we find that the Society has been very active in seeing that the Board of Health exercise its powers in abating the nuisances and sanitary dangers to which the poorer classes are especially liable. During ten months 956 complaints regarding these nuisances were received. Of these seventy-five per cent. were found to be well-fonnded, and action upon them was urged. A good work is thus being done here by the Association, since in many cases no relief would have been obtained without its interference.

We would suggest for the consideration of the Society a study of the question of the best methods of dealing

with the acutely sick or bed-ridden poor. There are thousands of poor families whose members dread the hospitals, and suffer great privations rather than go to these institutions. Methods of furnishing nurses, food, and medical aid to these persons might be devised. It is certainly better to cultivate among the poor a spirit of independence of charitable institutions of all kinds. When the poorer classes learn to think that they can send to a hospital any relation or dependent who becomes a little ill, it will be an unfortunate evidence of lack of independence as well as of sympathy and of the strength of domestic affection.

A LIFE THROWN AWAY.

Under the name of verruga, a peculiar eruptive disease, endemic in Peru, has been long known, but it would appear to have only recently excited the curiosity of the medical profession in that country. After an indefinite period of incubation, extending in certain cases during an entire twelvemonth, a peculiar warty or papular eruption makes its appearance, and is accompanied by severe and long-continued muscular and articular pains. The disease has never been much studied until within a few years past, and its nature and mode of origin are even yet involved in mystery.

Last August, Dr. Daniel Carrion, a resident of Lima, inoculated himself with the blood of a patient suffering from verruga, in order if possible to communicate the disease to himself, so that he might study its evolution. He was only too successful. After a period of incubation lasting twenty-two days he was seized with a grave fever, and despite energetic treatment, died seventeen days later. The symptoms of his disease were precisely those of another affection which had puzzled the physicians of Peru. This was a fever, differing in its symptoms from any recognized form of pyrexia, which had appeared among the laborers engaged in building a railroad in Oroya. It was called Oroya fever, and also anæmic fever, from the fact that excessive anæmia was one of the most prominent symptoms of the affection. It was supposed by some to be a form of malarial infection, while others, noting the fact that it was in Oroya that verruga was most prevalent, believed that there was an intimate relation between the latter disease and anæmic fever. The result of Carrion's costly experiment would seem to add weight to this latter theory. It is, however, not easy to discover any intimate relation between the two diseases, one an acute pyrexia, accompanied with profound changes in the blood, the other a chronic disease, requiring months for its development and characterized by a cutaneous eruption. But the descriptions of the diseases which we have seen are so meagre in details that it is impossible to form any intelligent opinion as yet concerning their supposed relationship. It is proposed to erect a monument to the memory of Dr. Carrion, and *El Monitor Médico* of Lima, has headed a subscription list for this purpose. While we think it right to honor the memory of one who has sacrificed himself in the cause of medical science, we cannot but hope that Dr. Carrion will have few imitators. Human life is too precious to be thrown away in mere experimentation, and the man who inoculates himself with the virus of an unknown disease, or who doses himself with a new drug in order to observe its toxic effects, without having previously ascertained its strength, is a fool, albeit a noble one. We have the lower animals to experiment upon, and we have no right to trifle with human life, whether it be our own or that of our neighbor.

MEASURE FOR RECONCILIATION.

It is beginning to be felt on all sides that, unless some immediate steps be taken to change the present aspect of matters, the Ninth International Medical Congress must fail, to the serious and lasting discredit of American medicine. The present Executive Committee, realizing this, recently made a slight effort at conciliation by tendering appointments on the Committee to several prominent gentlemen who had previously openly withdrawn from the organization of the Congress. These appointments, we are informed, have been declined; and matters are thus left in a worse state than before. *The Medical News*, in its last issue, makes an earnest and in some respects effective plea for mutual concession and reconciliation; and it suggests, finally, that harmony can yet be restored by the present Executive Committee adding to its membership the Original Enlarged Committee on Organization, and then beginning the work of organization *de novo*. Our contemporary's efforts are well meant. It is unfortunate that they should be marred by an exploiting of Philadelphia's services to the American Medical Association and its principles, which, to say the least, is irrelevant and not in the best taste. There is also a little of an anti-climax in presenting, as its scheme for securing harmony, a plea that restores its esteemed and able editor to office.

For all this, we feel safe in saying that the plan proposed will receive the support of The Medical Record, if it at the same time means that New York will receive recognition in the organization on a basis purely of the scientific attainments and honorable standing of its medical men. No more than this has been desired at any time, and for its self-respect the profession of this city and State can hardly ask less.

So far, indeed, as The Medical Record, voicing the feeling of the great body of its readers, is concerned, it asks no more than a just measure of recognition for New York physicians. It may be expedient to reappoint the Original Enlarged Committee. The profession at large, however, is indifferent to this point, since it feels that this Committee would have no right or inclination to oppose the Congress simply on account of personal disappointment. But the question of equitable representation, on a basis that introduces no side issues, involves a principle and is vital.

If the present Executive Committee will now officer its sections on this basis, it will have the full and enthusiastic support of the great mass of the profession and of the medical press.

Vaseline as a Food.—Dr. R. Dubois, of Paris, contends that vaseline is not a toxic substance, but, on the contrary, is digested in considerable amount, and acts as a food. Dubois' views are mainly based on experiments with dogs.

News of the Week.

Blisters do not draw well in warm weather, in this respect resembling some of our city churches. The reason in the case of the blister is that the skin is too moist, and water prevents the action of the cantharides.

Coca Leaves cost about fifty cents a pound, and contain from 0.4 to 0.6 per cent. of cocaine.

The Charity Organization Society of New York.—The Third Annual Report of this most useful Society has just been published. We are told that out of 55,000 dependent cases recorded it is safe to say that sixty-five per cent. have an able-bodied bread-winner, that is to say, 35,750 persons should be self-supporting, although now a burden on the community. As to medical charities, we are told that the applicants for relief at two leading hospitals and dispensaries are being investigated.

The International Congress of 1887.—The action of the Committee of the American Medical Association in its relation to the International Medical Congress of 1887 has already been sufficiently condemned in these columns. On all sides it appears that the prospect of a successful meeting under the auspices of the existing committee are *nil*, and we once more repeat our prophecy that the Congress of 1887, meeting in America, must be totally given up.—*Medical Press and Circular*, November 4th.

Childbirth Under Mesmerism. — Dr. Edward Pritzel, of Vienna, reports the case (*Wiener Medizin Woch.*) of a young woman, aged twenty-six years, who entered the maternity hospital of Professor Braun. It was found that she was very susceptible to hypnotic influence, and when her labor came on, as it was slow and painful, she was hypnotized. While in this state of artificial anæsthesia the child was born, with no pain and with but slight loss of blood.

The Support of Quackery.—"Charlatanism," says Dr. Holmes, "always hobbles on two crutches—the tattle of women and the certificates of clergymen."

Hospital Sunday.—The time is near at hand when the annual contributions for the hospitals will be solicited. Each private sectarian institution will be ready with its claim, and will strive to show how much it has done for the deserving poor. Offsetting this, it would be well on the part of prospective benefactors to ask for something beyond general statements. It would be worth while to inquire how economically these institutions are managed, how many of the deserving poor are treated, how many endowed beds there are, and how much medical charity is abused. Some of these institutions, which are too poor to attend to those patients they already have, are asking for increased accommodations.

The American Journal of Obstetrics and Diseases of Women and Children.—With the beginning of the next year this journal discontinues the Department of Diseases of Children as a distinct feature of the *Journal*. Dr. George B. Fowler, who has edited this department with marked ability and success, ceases his connection with the *Journal*.

Another Resignation from the International Medical Congress.—Another of the Vice-Presidents of the Congress, Dr. R. Palmer Howard, Dean of the McGill Medical Faculty, has resigned.

Some Good Advice.—"We looked hopefully to the action of the committee that met in Washington early in September for a harmonious and satisfactory solution of the honest differences between parties, but that committee was guilty of the most injudicious act that we would have supposed a body of intelligent gentlemen, intent on peace-making, could have planned. In its resolution to permit no change of a plan which was known to be unsatisfactory in its working, the committee exhibited a judgment that was "childish weak." The proper course to pursue—now that there seems to be so little reasonable hope of a successful settlement of differences between existing parties in time to inaugurate proper measures for the assembling of the Congress—seems to us to be the calling of a meeting of the American Medical Association in extraordinary session, rescind all resolutions relating to the Congress, except the one of invitation to meet in the United States in 1887, dismiss all committees that have been appointed, and declare as null and void all of their acts having reference to the Congress and then proceed *de novo*."—*Virginia Medical Traveller*

The Two-Thousand-Dollar Prize for a Cure for Epilepsy.—The prize of eight thousand francs offered by the Belgian Academy of Medicine for an elucidation by clinical facts of the "pathogenesis and treatment of diseases of the nervous centres, and principally of epilepsy," has not been awarded; but a sum of five hundred francs is offered by way of encouragement to the author of the essay bearing the motto, "Traditionem pondero, doctrinam respicio, sequor veritatem," on condition that he allow his essay to be printed in an abridged form with the criticisms of the Commission.

Monument in Bulgaria to Russian Medical Officers.—The last number of the *Ruskaya Meditsina*, says the *Lancet*, gives an engraving of a handsome monument recently erected in Sofia, Bulgaria, to the memory of 531 medical officers who fell in the Russo-Turkish War, 1877-78. It was planned by an Italian architect, and consists of a pyramid of rough blocks, on each of which are engraved the names of three or four of the deceased. The whole is surmounted by a capital of hewn stone, on the four sides of which are engraved the names of the chief battles in the campaign. A similar monument is to be erected in the Caucasus.

Medical Missionaries.—There was a medical students' missionary conference in the hall of the Young Men's Christian Association Building last Sunday, under the auspices of the Medical Students' Committee of the Association. Mr. L. D. Wishard, the American College Secretary, presided. Its object was to exhibit the field of labor for medical missionaries, as distinct from that for clerical missionaries, in heathen lands, especially China, India, and Western Asia. The Rev. Dr. Hopper, of Canton, China, said that the scheme was not a new one, as there are now eighteen hospitals and twenty-four dispensaries in China, which have been founded by medical missionaries, the oldest of which was established in

Canton in 1835. He gave instances of excellent work done by missionary physicians which had opened the way for the labors of their clerical associates. A number of addresses were made by other clergymen, and by Drs. C. R. Agnew and Wm. H. Thomson, and by Dr. E. A. Sturges, a medical missionary of Siam.

The Medical Age is one of the best exponents of American medical journalism, and we read its columns with interest and profit. Something, however, has of late gone wrong with its Latin editor. Perhaps the overstudy of medical cases has made him careless of his genitives; at any rate, we would respectfully correct his statement that "*Salus populus* may be *suprema lax*," and would suggest the dropping of a vowel in his announcement that college rivalry in Buffalo is a "*causus belli*" Our esteemed contemporary writes capital English, and after all it may be only the spirit of evil at the printing-office that spoils its Latin.

The Shady Side of Medical Education in California.—"A medical graduate" writes to a contemporary complaining of an article which recently appeared in the *News Letter* in regard to the methods of manufacturing medicos which prevails in this State. We pointed out that there were "five so-called medical colleges in San Francisco and Oakland that we knew of, besides others that work in the dark that we were not acquainted with, that sell diplomas for coin." It was a monstrous system of quack-manufacturing which the *News Letter* hammered away at for two years before it could get the righteousness of its criticisms admitted. We insisted that students should evidence, by a matriculation examination, that they possessed sufficient scholastic education to read the language of medical science understandingly. We furthermore pointed out that the period of study should be at least doubled. Four years is the least time in which a medical student can be expected to attain to even mediocrity in the knowledge of his profession. California lacks hospital facilities necessary to the thorough education of skilful physicians; it also lacks experienced teachers with spare time to enable them to do full justice to their classes. A Californian medical diploma is not at present an evidence of professional attainments that inspires confidence in the public, or causes its holder to feel proud of its possession. We regret to say these things, but it is our respect for the noble art of healing which makes us say them. We regard the medical profession as the grandest on earth, and it is our sincere desire to exalt it which impels us to protest against local methods of manufacturing quacks. —*San Francisco News Letter.*

As it looks at St. Petersburg.—Some complaints have been made that the real condition of the affairs of the next International Medical Congress has not been correctly apprehended abroad. The following editorial note from the *St. Petersburg Medicinische Wochenschrift* of November 21st shows that matters are a little mixed in Russia, in this respect comparing favorably with Chicago. "The prospects of the next (Ninth) International Medical Congress, which was to meet in 1887 at Washington, have lately, in an unusual manner, been put in jeopardy. The original Organizing Committee, of which, as announced by us in previous communications, the well-known Surgeon-General of the U. S. Army was secretary-general, and to which the most distinguished American physicians belonged, has been retired. This was accomplished through the intrigues and hostility which developed at the last Annual Meeting in New Orleans. At this time, a new committee was appointed under the presidency of a Dr. Shoemaker (Philadelphia). This new organization committee contains but a few of the members of the previous committee, and is composed mostly of unknown and insignificant physicians, who inspire no confidence in their capacity for conducting the Congress. Under such circumstances, any co-operation from foreign countries can hardly be expected."

A Canadian View of the International Congress. —The prospects of the Washington Congress of 1887 do not appear to grow brighter, and the tone of the great medical weeklies of the eastern cities shows very plainly that there is still war between the adherents of the old and the new committees. It is a great misfortune that there does not seem to be any central executive of the Congress which could step in and say: Stop this unseemly quarrelling at once, or we shall go elsewhere! But apparently the meeting must take place in Washington or not at all. The latter alternative would be preferable if a reconciliation is not effected; for, if matters remain as they are, it will be impossible to organize the sections with men of sufficient reputation to command success. To attract the workers of other countries the sections must be controlled by the men most eminent in their respective departments, but the present officers of sections, with few exceptions, do not reach beyond a respectable mediocrity, and are men that we cannot regard as representative. If the executive cannot secure the return of the leaders in thought and work, and fails to engage their hearty co-operation, but one thing remains to be done, and in the interests of the profession of the United States, it should be done soon—give it up. Better no Congress than a prolongation of this unseemly strife.—*Canada Medical and Surgical Journal.*

Some Recent Malpractice Suits.—Another suit of a blackmailing character has been brought against Dr. E. Williams and partners, of Cincinnati, O. According to the *Cincinnati Medical News* the charge was that they had permitted a small scale of iron that had entered the eye of a boy to remain, by which he eventually became blind—the sound eye becoming affected through sympathy with the injured one, and losing the power of vision. It was proven on the trial that the boy had visited the office of Dr. Williams but twice, and then had ceased calling because he was informed that to preserve the sound eye and be saved from blindness he must consent to have the eye that had been destroyed removed from its socket, to which his parents would not consent. For several months, after declining the services of Dr. Williams and associates he spent his time in going the rounds of the specialists of diseases of the eye, putting his case in charge, at different times, of both regular and homœopathic physicians. Every ophthalmologist by whom he was treated informed him that the only way by which he could avoid becoming blind was to have the injured eye removed. Finally, after losing sight in both eyes, he brought suit. The medical testimony, we are

told, was uniformly in favor of Dr. Williams, but the jury disagreed.—The Boston correspondent of *The Northwestern Lancet* writes: "Dr. A., a reputable practitioner living in a New England city, attended Mr. B. for a fractured thigh. The case did well, and the patient recovered without deformity. No measurements were recorded by the attending surgeon, but he was able to swear that the result was to him perfectly satisfactory. A year or two later the patient entered suit against Dr. A. for malpractice, and exhibited a leg considerably shortened and deformed. A jury at once found a verdict for the plaintiff, and awarded damages in some $6,000 or $7,000, a sum which seriously crippled the physician. He devoted his energies thereafter to discovering what he believed to be a fraud, and finally obtained evidence that B. had, subsequently to his recovery under A.'s attendance, again fractured the same thigh while in the Adirondack wilderness, and had on that occasion had no surgical attendance whatever. The physician was able to recover his money, but was at the expense of his detectives' and lawyers' fees, to say nothing of years of anxiety and of damage to his professional reputation."—A suit is just now in progress against a prominent gynecologist of Boston, connected with a free hospital for women. The plaintiff charges that she was entered into the hospital under invitation of the physician, who "met her somewhere," and told her he could cure her if she would come into the hospital. She did so, she says, not dreaming of an operation, until one day she overheard the nurses talking in a way which excited her suspicion. She was told that no operation was contemplated, and was reassured. But one day she came to her consciousness from ether to find herself being sewed up. She further deposed to having been discharged from the hospital onto the sidewalk upon a winter's night when she had no place to go, a usual fashion of eleemosynary institutions. She claims from the physician who gave his time and skill, and the hospital which gave its bed, board, and nursing, all without expense to herself, $10,000 apiece.

New Polyclinic College Building in Philadelphia.—The new building for the Philadelphia Polyclinic College, on Broad Street, will soon be ready for its occupants. The attendance at the college by the students from all parts of the country has increased beyond the capacity of the present quarters at Thirteenth and Locust Streets. The new building will contain more hospital wards and private rooms for pay patients, and the dispensary service will be given more attention. The journal edited by the faculty will be doubled in size after the first of the year.

St. Louis Obstetrical Society.—At the annual meeting of the St. Louis Obstetrical and Gynecological Society, held on November 18th, the following officers were elected: President, Dr. W. M. McPheeters; Vice-President, Dr. Walter Coles; Recording Secretary, Dr. I. M. Scott; Corresponding Secretary, Dr. E. C. Gehrung; Treasurer, Dr. Chas. E. Briggs.

The late Mr. W. H. Vanderbilt.—At a special meeting of the Faculty of the College of Physicians and Surgeons, the Medical Department of Columbia College, in the City of New York, held on December 10, 1885, the following preamble and resolutions were unanimously adopted:

Whereas, By the death of William H. Vanderbilt there has been taken from the community a citizen from whose hands this college has received a splendid addition to its means of usefulness, be it

Resolved, That we offer hereby our tribute of mourning for the loss of a benefactor, whose services to the advancement of education has been great and enduring—as broad in scope as free in gift—and whose enlightened generosity will ever be held in grateful remembrance by ourselves and our successors.

Resolved, That we tender our heartfelt sympathy to the family of the deceased in their bereavement.

Resolved, That, as a token of respect, all exercises at this college be suspended on the day of the funeral, and that we attend the same in a body.

Resolved, That these resolutions be communicated to the family, and be duly published.

John G. Curtis, M.D.,
Secretary of the Faculty.

College of Physicians and Surgeons, Medical Department of Columbia College.—At a meeting of the Board of Trustees, held December 15, 1885, the following preamble and resolutions were unanimously adopted:

Whereas, By the death of Mr. William H. Vanderbilt the cause of medical education in this country has lost one of its first conspicuous benefactors; and, whereas it becomes the duty of the Trustees of the College of Physicians and Surgeons, which was the object of his sagacious benevolence, to express their deep sense of the debt due to his memory; therefore,

Resolved, That Mr. Vanderbilt's gift toward the advancement of medical knowledge reaches a higher mark in the intelligent disposition of wealth than has often been attained by public benefactors; for it recognizes science as the handmaid of humanity, and acknowledges the benefits of the healing art in controlling human misery and enhancing human happiness.

Resolved, That it is a source of profound regret to this board that Mr. Vanderbilt's life was not spared to witness the completion of the college building which his generous endowment projected, and which will become his most worthy and enduring monument.

Resolved, That these resolutions be inscribed upon the minutes of this board, and that a copy be sent to the family of the deceased, with the assurance of our respectful sympathy for them in their great affliction.

John C. Dalton, M.D., *President.*
George G. Wheelock, *Registrar.*

Another Cure for Cancer.—In a case of alleged epithelioma involving the facial bones, with extensive infiltration of the tissues, where an operation was not deemed desirable, Dr. Antonio, of Mazzara del Vallo Maggio, applied an ointment consisting of fifteen parts of resorcine to twenty parts of vaseline twice a day, with the result, it is said, of completely curing the disease; nothing remaining but a white scar a centimetre in diameter.—*British Medical Journal.*

Hydrastis in Dyspepsia.—Several correspondents in *The Lancet* have lauded hydrastis as a most useful drug in dyspepsia.

Reviews and Notices.

THE DISEASES OF SEDENTARY AND ADVANCED LIFE. A Work for Medical and Lay Readers. By J. MILNER FOTHERGILL, M.D., Physician to the City of London Hospital for Diseases of the Chest (Victoria Park), Late Assistant Physician to the West London Hospital; Hon. M.D., Rush College, Chicago; Foreign Associate Fellow of the Royal College of Physicians of Philadelphia. New York: D. Appleton & Co. 1885.

THIS work, as its sub-title indicates, is written in a popular style, and the employment of technical terms, not understood by the laity, is, as far as possible, avoided. But, unlike most books of its class, it contains much that even experienced practitioners will find of value, although they may not always be able to assent to all the author's conclusions. Many of the views here advanced will be found treated more fully in some of the writer's previous works, especially in his book on "Indigestion and Biliousness;" but there is also much that is new, and even what is old is presented in a new light, and will bear perusing a second time. The work is divided into three parts, treating respectively of early life, adult life, and advanced life. Part II., in which the troubles incident to enforced bodily inactivity during the period of adult life are discussed, is the one which possesses the greatest interest for the average reader. In it the clerk, the machinist, the governess, the invalid and her companion, the merchant, the accountant, the literary man, and schoolmasters and -mistresses, each have a chapter devoted to the peculiar mental and physical ailments which their occupation entails upon them, and containing suggestions as to how they can best avoid the dangers of their respective callings. There are other chapters on enforced idleness resulting from a broken leg, a sea voyage, weak heart, and the like, and on hemorrhoids, rheumatism, the change of life, and common ailments and abnormal conditions. Part III., deals with the aged and their infirmities, and contains many little hints and suggestions as to how the declining years of life may be rendered comfortable, and the diseases peculiar to this period may be made less burdensome. Those who are acquainted with Dr. Fothergill's pleasant manner of writing will need no assurance from us to believe that there is no task involved in reading this book. Its perusal will prove to be a pleasant recreation in an evening following a hard day of toil. The proof-reading does not seem to have been performed with any too great care, for in many places the punctuation marks are displaced in such a way as to mar the sense somewhat, and we have never before heard that there was a Royal College of Physicians of Philadelphia, as is stated on the title-page.

TRATADO PRÁCTICO DE LAS ENFERMEDADES DE LAS MUJERES, por el DOCTOR GAILLARD THOMAS. Segunda Edicion Española, corregida y aumentada con seis capítulos, ciento un grabados nuevos, multitud de notas de la última edicion inglesa, un prólogo y un apéndice terapéutico, por el DOCTOR JUAN GARCÍA PURON, ex-Médico-cirujano del Ejercito Mexicano. A Practical Treatise on the Diseases of Women, by Dr. Gaillard Thomas. Second Spanish Edition translated by Dr. Juan García Puron. New York: D. Appleton & Co. 1885.

THE first Spanish edition of this standard work of Thomas on the Diseases of Women was published in 1879, and it became at once so popular among the physicians of Central and South America that it was almost impossible to supply the demand for it. And even while the second edition was in press it was found necessary to send out a new impression of the first in response to the imperative orders for the book which would admit of no postponement. We need say nothing as to the work itself, for it is so well known and prized by all that any words of commendation would be superfluous. And it is a pleasure to find that the book has suffered little, if at all, by its change of dress. The translation is idiomatic, yet preserves, as far as is possible, the easy and pleasant style of the original, and the typographical execution leaves nothing to be desired. The notes of the translator are judicious and not too long, and add to the value of the book. In fine, our Spanish-American brethren are to be congratulated upon their good fortune in having had this invaluable work presented to them in their mother tongue.

THE PEDIGREE OF DISEASE; being Six Lectures on Temperament, Idiosyncrasy, and Diathesis, delivered in the Theatre of the Royal College of Surgeons in the Session of 1881. By JONATHAN HUTCHINSON, F.R.S., late Professor of Surgery and Pathology in the College; Emeritus Professor of Surgery in the London Hospital; President of the Ophthalmological Society, etc. New York: William Wood & Co. 1885.

MR. HUTCHINSON has given us in this book a really excellent *résumé* of all that is known of the subject, and presents it in such a way as to convince his readers that they have erred in their readiness to ignore the teachings of a past generation. Our fathers perhaps laid too great stress on temperament and diathesis, but we have been in danger of going too far in the opposite direction, and in our eager study of the pathology of diseases have in a measure lost sight of the individual peculiarities which modify their course. It was the desire to counteract this tendency that led the author to deliver these lectures, and afterward to publish them in book form. Apart from the importance of the subject, the easy style in which the lectures are written makes their perusal a pleasant recreation as well as a profitable employment, and we feel sure that no one who gets the book and reads it will regret having done so.

PRACTICAL HISTOLOGY AND PATHOLOGY. By HENEAGE GIBBES. Third Edition. Philadelphia: P. Blakiston, Son & Co. 1885.

THE directions in this manual for staining, preparing, and mounting tissues are given clearly and concisely, and the methods recommended are those which the author has found "the best, easiest, and cheapest." It is not evident, however, that these are presented in any better manner than has been done by American teachers of this subject. The directions relative to the kind of instruments, and the purchase of the same, with the exception of the microscope, relate to London dealers for the most part, and, therefore, are not useful to American students. This portion of the book might well have been revised with this in mind, and dealers in this country recommended.

POST-MORTEM EXAMINATIONS. With Special Reference to Medico-legal Practice. By PROFESSOR RUDOLPH VIRCHOW. Translated by T. P. SMITH, M.D. Philadelphia: P. Blakiston, Son & Co. 8vo, pp. 138. 1885.

THIS little book is written in a practical spirit, and contains a wealth of valuable information. No physician can afford to remain ignorant of the maxims pertaining to the technique of post-mortem examinations. In the first place, rare cases, presenting points of great interest from a pathological point of view, are liable to occur in the practice of any physician. It is an unfortunate fact that such valuable material often goes to waste, simply because the practitioner is unable to avail himself of the most approved methods of post-mortem research. Again, the practitioner is sometimes called to give legal testimony, the value of which is in part, or even wholly, contingent upon his ability to conduct a scientific autopsy. It will thus be seen that the *raison d'être*, of Dr. Virchow's book is well established both on theoretic and practical grounds.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 3, 1885.

ABRAHAM JACOBI, M.D., PRESIDENT, IN THE CHAIR.

DR. MORRIS H. HENRY read an interesting review of the life of

LOUIS ELSBERG, M.D.,

in which he also took a glance at the advancement of our knowledge on diseases of the throat during the last thirty years.

The subject of his memoir was born at Iserlohn, Prussia, April 2, 1836; he graduated in medicine at the Jefferson Medical College, Philadelphia, in 1857. In 1861 he delivered a course of lectures at the University Medical College. The following year he established the first public clinic for diseases of the throat.

Dr. Henry then mentioned the varied contributions to medical literature made by Dr. Elsberg, and said that he "was the first, beyond any question, to demonstrate and teach in public, in this country, the use and value of the laryngoscope in diagnosis and treatment. He leaves many disciples among his former pupils who will continue the same course of investigations. The best work of his life, however—the work that inures most to his fellow-men—was the diffusion of his knowledge and experience in such a way that all practitioners might render good special service to their clients.

"During that period of excitement pending the discussion of 'the code question' Elsberg could not be otherwise than thoughtful and liberal. He was gentle in the expression of his opinions. He was intense in his convictions. He never faltered in the discharge of an obligation or duty when once assured of its correctness and the probability of its serving a good purpose. While he was registered—if I may use the term—as a 'new-code man,' and I on the other side of the question, there was, in reality, no difference whatever in the substance of our views. A calm discussion of the questions at issue proved us in unison. Might not more forbearance have prevented the strife that disorganized associations and dissevered friendships of a lifetime? A calm, retrospective review of the field of battle tells again the sad tale of 'what might have been' had wiser counsels prevailed. Elsberg shared the common feeling of all educated, thoughtful, honorable practitioners of medicine, that there should be no necessity for a code beyond that unwritten code of ethics that should govern the conduct of gentlemen in every sphere of life. He knew of, and fully appreciated, the difficulties of any enforcement of a statutory enactment or a professional mandate against persons devoid of honor and unworthy of fellowship in a liberal profession. He knew also that the attainment of this boon—a difficult one—could only be reached by the imperative demand of the profession at large that the mills should be stopped, and that there should be no more enlistments of ill-formed, improper persons to the ranks of our sacred calling. He knew also that you can neither teach nor enforce virtue by resolutions or text-books. He knew, Mr. President, as you and I know—no one better than yourself—that the enlightened men of this country, the class that have shed most lustre, that have attained most honorable distinction, whether now rated (by irresponsible and illiberal factions) as new or old code adherents, are of one accord. The admission of the necessity of a special code—it is useless to deny it—is virtually an admission that the rank and file of the profession in this land is inferior in moral integrity to that of all other countries. I, sir, am unwilling to admit of any basis for any such conclusions.

"From one of his people—descended of those born on Latin soil, the same that gave birth to the Disraelis, Montefiore, Jessel, Aguilar, and Castelar, brilliant in art, literature, law, statesmanship, and humanity, not less dazzling to science—we are indebted for the first account, by the use of the laryngoscope, of the action of the vocal cords during inspiration and vocalization, important observations on the production of sound in the larynx, and valuable reflections on the formation of the chest. The story of the investigations of Manuel Garcia, who published, in the year 1855, in the proceedings of the Royal Society of England, his physiological observations on the human voice, is too well known to you to call for further reference on this occasion.

"If the utility and value of a life be measured by the advantages which accrue from the love, devotion, and labors of those ever ready to sacrifice self in ministering to the ills of poor suffering humanity, surely no one will now deny a worthy site to the memory of our late friend and Fellow of this Academy."

A paper was read on

ORIGINAL DEDUCTIONS BASED ON A STUDY OF ONE HUNDRED CASES OF FRACTURE OF THE UPPER EXTREMITY, EXCLUDING THE HAND,

by DR. SAMUEL W. SMITH. (See page 673.)

DR. JOSEPH D. BRYANT said the lateness of the hour would permit of only a few remarks, which he would make regarding fracture of the clavicle. The cause of the deformity which occurred in this fracture had given rise to a great deal of discussion, some claiming that it is due to muscular contraction, others to failure of the clavicle to hold the shoulder in position, others to contraction of this or that group of muscles. In Dr. Bryant's opinion the deformity depended upon the fracture of the clavicle, and not upon muscular contraction resulting from it. He believed that the function of the clavicle is to hold the shoulder backward, upward, and outward, and whenever the clavicle is broken in such a position that the fragments can override each other, the shoulder then falls downward, forward, and inward. If the fracture should occur at the inner or outer third there would be little deformity, but if at the insertion of the trapezius and deltoid muscles on the one side, and of the sterno-cleido-mastoid and pectoralis major on the other, there would always be marked deformity. He could not agree with the author of the paper that contraction of the subclavius muscle had particularly to do with the production of the deformity; that is, it had not a predominating influence.

As to treatment, any apparatus which would meet the indication, that is, confine the fragments in position, would secure as good results as any other. He had used the adhesive plaster of Dr. Sayre frequently, and it met the indication. Dr. Moore's method also met the indication. The apparatus which Dr. Smith presented also met the indication so far as he was able to judge from a casual examination, and if it did meet the indication he should think it had advantages over the other two methods mentioned—not that it would produce better results, perhaps, but because the results were obtained with less discomfort to the patient. He thought well of it.

DR. A. C. POST said, with regard to the portion of the clavicle in which fracture takes place, that the most important distinctions were in those occurring on the inner side of the coraco-clavicular ligaments, those occurring between the coronoid and trapezoid ligaments, and those occurring on the outer side of the trapezoid ligament. When fracture took place in the inner three-fourths of the clavicle, there was usually some deformity; the clavicle was shortened, the shoulder falling, so that the outer fragment fell below the inner. When fracture took place between the conoid and trapezoid ligaments, both fragments being tilted by the ligaments binding them to the coracoid process, there was almost no deformity, and it was very difficult to make a diagnosis. Very little treatment was required other than rest and support of the arm

in a sling. When fracture occurred at the outer side of the trapezoid ligament there was considerable deformity, but of entirely a different character from that which existed after fracture on the inner side of the conoid ligament; the shoulder is thrown forward, and the short fragment is placed at nearly a right angle with the long fragment, and on nearly the same level; there is no falling.

Dr. A. H. Goelet had improvised an apparatus from roller bandage, similar to that employed by Dr. Smith, in a case of fracture of the clavicle which was first treated after Dr. Sayre's method by adhesive plaster, which caused great annoyance. Dr. Smith's plan gave the patient complete comfort.

Dr. Smith, in closing the discussion, said he divided the clavicle into thirds, after the plan of Hamilton. If fracture should take place in the outer third the deformity would be less than in fracture at the inner third, but the former locality had been selected in only one of his cases.

Dr. C. R. Agnew offered the following resolution:

Resolved, That it is the opinion of the Academy of Medicine that any judicial action which in its effect discourages members of the medical profession in making early reports to the Board of Health of cases of supposed contagious or infectious disease is contrary to public policy and most detrimental to the interests of public health. Carried unanimously.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

ROYAL MEDICAL AND CHIRURGICAL SOCIETY—ANTHRAX AND THE DISTRIBUTION OF THE BACILLUS ANTHRACIS IN THE HUMAN SKIN—TUBERCLE OR ACTINOMYCOSIS—THE MEDICAL SOCIETY OF LONDON—ACUTE TRAUMATIC MALIGNANCY—THE COLLEGE OF SURGEONS—THE GENERAL ELECTION AND MEDICAL CANDIDATES—THE HOSPITAL SUNDAY FUND AND RELIGIOUS INTOLERANCE—GASTRIC ULCER AND ITS TREATMENT—GASTROSTOMY AND JEJUNOSTOMY—MEDICAL MEN IN PARLIAMENT—THE MOVEMENT FOR ESTABLISHING A TEACHING UNIVERSITY.

London, November 27, 1885.

The last meeting of the "Medical and Chirurgical" was more scientific than interesting. The subjects discussed were rather abstruse, and could only be expected to interest a small section of the Fellows. The papers read were, however, pretty fully discussed.

The first paper was by Mr. A. E. J. Barker, Assistant Surgeon to University College Hospital and well known as the translator of Frey's Histology. Mr. Barker narrated the history of a case of malignant pustule occurring in a young man. The growth, which was on the left side of the neck, was excised and the patient recovered. Mr. Barker had examined microscopically the parts removed, and had arrived at the conclusion that the organisms (bacilli anthracis) had a remarkable predisposition for the most superficial parts of the dermis and only penetrated into the deeper parts slowly and in relatively small numbers. He found enormous colonies spreading over the surface of the papillæ, causing vesiculation of the epidermis. He found only a few scattered baccilli in the bodies of the papillæ and in the deeper parts of the cutis. None were detected in the vessels of the skin. Under the eschar the active growth of the organisms appeared to have been arrested.

The next speaker was Mr. Davies-Colley, Surgeon to Guy's Hospital. Mr. Davies-Colley thought that Mr. Barker had exaggerated the local character of the disease. In his own experience, he said, the system rapidly became affected. He referred to the fact that bacilli had been found in the various secretions of the body, and within a short time of the development of the local disease. Mr. Davies-Colley subsequently stated, in reply to a question from Mr. Barker, that the only case in which the bacilli were detected in the various secretions recovered. This fact seems to throw some doubt on the accuracy of the diagnosis.

Dr. Turner, Assistant Physician to the London Hospital, followed, and to a large extent concurred with Mr. Barker as to the marked localization of the affection. A line, he said, could be distinguished across the section above which the bacilli were numerous, and the tissues in a state of necrosis. Below this line the bacilli were few in number and the tissues still living.

The next proceeding in the programme for the evening was the reading of a paper on a case of liver-disease by Dr. John Harley, Physician to St. Thomas' Hospital. An hepatic abscess had formed and had been incised. Small quantities of thick, creamy pus were constantly discharged, and the patient finally died of exhaustion. There was only slight pyrexia throughout. The patient presented the usual aspect of tubercle. At the post-mortem several morbid masses were found in the liver. From the morbid anatomy of these masses, Dr. Harley endeavored to show that the case in question was one of tubercle, although he admitted that they exhibited very distinctly the character of actinomycosis. His contention, in fact, was that most, if not all, of the cases which have been regarded as examples of actinomycosis have really been cases of tubercle.

Dr. Harley's paper was very elaborate, and was evidently intended to carry conviction to the minds of his hearers. Nevertheless it failed to do so, and when his paper was concluded a general onslaught was made upon him. The speakers were Dr. Seymour Sharkey, Dr. Theodore Acland, Mr. Shattock, Dr. Percy Kidd, and Mr. Watson Cheyne. The general opinion seemed to be in favor of the distinct existence of actinomycosis, and several of the speakers considered Dr. Harley's case to be really an example of that disease.

At the last meeting of the Medical Society of London the entire evening was devoted to the discussion of the subject of "Acute Traumatic Malignancy." The discussion was introduced by the reading of a paper by Mr. Pearce Gould, Assistant Surgeon to University College Hospital, and Surgeon to the London Temperance Hospital, on a case in which sarcomata rapidly followed injury, and in which he amputated at the hip-joint. A very lively and interesting discussion followed. Many of the speakers narrated cases bearing on the subject discussed, and the opinions expressed in the course of the discussion showed pretty plainly that the condition termed acute traumatic malignancy has now received wide and general recognition.

Since my last letter the Council of the Royal College of Surgeons have held another meeting, at which the minutes of the previous one were confirmed. The Council are determined to resist reform *à l'outrance*. Whether twenty-four men can in the end succeed in thwarting the declared wishes of nearly seventeen thousand remains to be seen. I trow not—at any rate not for long.

By the time this appears in your columns the general election will be over and its results known. Just now it is overshadowing in interest all other subjects—both professional and general. There are but few medical candidates for Parliament. Mr. Ernest Hart has just been defeated in East London. Mr. Erichsen is believed to stand a good chance for the Universities of Edinburgh and St. Andrews. The new House of Commons, however, is not expected to contain many new medical members. The profession will probably be represented by at most a dozen members. Politics, as such, does not have many charms for most of our profession. A political life necessitates retirement from practice—it might almost be said, retirement from the profession. Such is not the case with the law, and many successful barristers continue to practise their profession while retaining a seat in the House. Moreover, in the law there are some

very substantial rewards for the barrister who becomes a successful M.P. The law officers of the Crown are chosen from among them. No such prizes as these even—to say nothing of the post of Lord Chancellor—await the physician or surgeon who forsakes physic to embark on the troubled sea of politics.

London, December 5, 1885.

The dispute which has been going on in the Council of the Hospital Sunday Fund, with reference to the alleged religious intolerance as regards the nurses at University College Hospital, has suddenly terminated in an amicable manner. As already mentioned in a previous letter, the controversy originated in the refusal of the authorities of University College Hospital to admit a Nonconformist to be trained as a nurse in their institution. It transpired, on inquiry, that the nursing at University College Hospital is entirely entrusted to a nursing "sisterhood" of marked High-Church principles. Hence the refusal. The matter was brought before the Council of the Hospital Sunday Fund by a prominent Nonconformist minister (Dr. Allon) and threatened to have serious consequences, as it appeared not improbable that Nonconformists might decline to contribute in future to the fund. The result would, of course, have been a serious loss. The question was referred for consideration to the General Purposes Committee. They have just brought their report before the Council. They virtually state that they cannot interfere, on the ground that "matters relating to the internal administration of hospitals are beyond the jurisdiction of the Hospital Sunday Fund." The adoption of this report was moved, and Dr. Allon seconded the motion, thereby withdrawing his opposition. The motion was carried unanimously, and an incident which promised to lead to serious results has thus terminated peaceably. The publicity which the affair has caused will doubtless lead to a reform in the arrangements at University College Hospital. The Hospital Sunday Fund continues to prosper. The receipts for the present year exceed thirty-four thousand pounds. The working expenses have been between eleven and twelve hundred pounds.

The last meeting of the Medical Society of London was entirely devoted to the consideration of the subject of ulcer of the stomach. The discussion was introduced by the reading of a paper by Dr. Stephen Mackenzie. Numerous remedial agents were recommended by the various speakers. Mr. Edmund Owen made the apt remark that physicians might learn something from surgeons. In his opinion uninterrupted rest was as necessary for a gastric ulcer as for an inflamed joint. "Mashed potatoes and pills" he characterized as "bad treatment."

At the Clinical Society's last meeting several interesting cases of gastrostomy were brought forward. This operation has now been performed a considerable number of times by British surgeons, and the proportion of successful cases is growing larger.

Mr. Golding-Bird then narrated the history of a remarkable case in which he had performed jejunostomy. The patient was a man, aged forty-six, who was admitted into Guy's Hospital after having suffered from symptoms of pyloric obstruction for ten months. A tumor could be felt near the pylorus. There was extreme emaciation, due partly to actual inability to retain the food ingested, and partly to the patient voluntarily starving himself to escape the pain which ensued on eating. After three weeks of medical treatment he was transferred to the surgical wards.

The patient having consented to an operation, Mr. Golding-Bird cut down on the pylorus with the intention of performing pylorectomy in Billroth's manner, but was disappointed by finding the tumor adherent to the liver. He therefore resolved to abandon the radical operation he had projected, but to convert it into a palliative one by opening the jejunum. The jejunum was seized and attached to the edges of the wound. On the third day after the operation the bowel was opened, and from that date the patient was fed solely through the jejunal opening. All went well until the ninth day, when some food was unfortunately allowed to pass into the peritoneum, and the patient died in twelve hours. During the week he was fed *per jejunum* the curious observation was made that when the meal was as much as a pint it was followed by severe indigestion, while one of only ten ounces caused no inconvenience. From this Mr. Golding-Bird suggested that possibly some cases of indigestion are due to the pylorus allowing a too free passage of chyme rather than to disturbance of the gastric or pancreatic secretions.

Only a dozen medical men have found seats in the new Parliament, and of these quite one-third, although qualified medical men, are not such by profession, having engaged in other pursuits. For instance, Dr. Vanderbyl forsook medicine for banking twenty-seven years ago. A few elections still remain to be decided, but the representation of the profession is not likely to be much increased.

The Association for Promoting a Teaching University for London have just held a general meeting. No decided move has yet been made. The Association labors under the fatal mistake of not being able to make up its own mind. It is at present wavering between three alternatives, viz.: 1. To endeavor to procure the reconstruction of the present University. 2. To institute a Teaching University, which shall exist side by side with the present one, and be in close relation with it. 3. To found a new and totally independent University, with which existing teaching institutions will be associated. The relative favor apparently accorded to these several schemes by the Association is indicated by the order in which I have given them. The reverse order would, however, better indicate the *practicability* of each. It is largely believed that any great change in the present University is not to be expected. The second scheme is almost as chimerical. The last scheme would, however, command great support, both pecuniarily and otherwise.

ON THE REPORT OF THE COMMITTEE ON DISINFECTANTS OF THE PUBLIC HEALTH ASSOCIATION.

A Reply to Dr. Sternberg.

To the Editor of The Medical Record.

Sir: It is with considerable hesitancy, and contrary to my previous determination, that I prolong, even by a short note, the unfortunate discussion that I have been led into by Dr. Sternberg. I know very well that nothing is gained by bringing personal matters before the public, but it is not easy to treat with deserved contempt accusations that are, and can be shown to be, absolutely false. Without taking up space with further apologies, I wish to close the discussion (so far as I am concerned) with the following brief comments on Dr. Sternberg's last article:

1. No better evidence can be had that Dr. Sternberg's idea is to distract attention from the mistakes of the report by making the discussion purely personal, than that in his last reply he pays no attention whatever to the principal point under discussion, viz.: the use of potassium permanganate as a coloring agent, and his attempt to get it out of the solution by adding chloride of lime.

2. Although he now claims that my experiments made with him, on Squibb's liq. zinci chlor., had no bearing on his own, at the time he specially quoted them as sustaining his previous determination (*Medical News*, January 18, 1885, p. 33). Even if we take his own statement as correct, it strikes me that experiments on the unknown contents of stray bottles should not be published as a guide to the profession in sanitary matters.

3. In order to acquit myself of the charge of reporting

a private conversation that I overheard, I am compelled to give the following particulars, which otherwise I would much prefer to leave unnoticed. The agreement Dr. Sternberg requested Dr. Abbott to make was *not* that he should remain with him for a year, but "that he would not accept of a position from Dr. John S. Billings if it was offered him, as that gentleman was desirous of securing an assistant familiar with his methods of work." Moreover, I did not overhear the conversation, but Mr. Lee, of the Biological Laboratory of the Johns Hopkins University, and myself were present, and were asked by Dr. Sternberg to witness the verbal agreement.

Now, I do not simply place my own word in opposition to Dr. Sternberg's in this matter, but refer to Dr. Abbott and Mr. Lee for the confirmation of these facts. There is certainly no reason why these gentlemen should be prejudiced in my favor, and if they will say that I have in any way incorrectly reported the conversation, I am ready to forfeit the entire confidence and respect of the profession.

Dr. Sternberg has done too much good bacteriological work for me to say anything that affects his reputation, except in so far as he has made it necessary for me to preserve my own; and, to avoid further unpleasant complications of this kind, I will take no further notice of any statements except such as pertain solely to the points of the report mentioned in the article by Mr. McClintock and myself. J. R. DUGGAN, M.D.

JOHNS HOPKINS UNIVERSITY, December 12, 1885.

EQUINE SCARLATINAL VIRUS AS A PROPHYLACTIC AGAINST HUMAN SCARLATINA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Since the publication of my first article on the use of "Equine Scarlatinal Virus as a Prophylactic against Human Scarlatina" (MEDICAL RECORD, March 24, 1883), I have carefully considered the statements made at that time, and I am led to say they were untruthful, for I do not believe the injection of the equine virus into the subcutaneous tissue of the rabbits and dog, produced a "confluent eruption" similar to scarlatinal rash. I also believe that the "furfuraceous exfoliation" and the enlargement of the lymphatics could be accounted for by the slight traumatic inflammation.

The injection of the virus under the skin of the twelve patients reported produced a redness, but I am inclined to think, as a result of more recent trial, that it was not a scarlatinal eruption. With reference to the injection of the human scarlatinal blood I can only say that if it contained the active poison of scarlet fever it certainly failed to reproduce the disease, and that might be evidence in favor of the protective power of the equine virus, but I am disposed to believe that the blood was inert. I take it that in scientific investigations it is only honest and true to frankly acknowledge error in the interpretation of phenomena, carelessness as to detail, or mistakes in deductions. I am aware that conscience is just as certain to condemn or approve in the domain of science as to set up a tribunal within a man, by which his own actions are judged in any other field of labor.

I am continuing the investigations I began two years ago, and I have reason to believe that, notwithstanding the apparent failure thus far, a satisfactory solution of the problem will be arrived at in due time.

Yours respectfully,
J. W. STICKLER, M.D.

SPONTANEOUS ORIGIN OF TYPHOID FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I noticed some time ago, in THE MEDICAL RECORD, the discussion of this question in the New York Academy of Medicine, and have been expecting to hear from a good many physicians situated in sparsely settled portions of the country on this subject. I think physicians so situated should contribute such testimony as they may have on this subject, as it is impossible for those in large cities with a dense population and all their surroundings ever to decide this question. I would like to hear the experience of country physicians, to see how many have arrived at the same conclusion. I see, in THE MEDICAL RECORD of November 21st, Dr. Ambrook produces valuable testimony as to its spontaneous origin on the mountains and plains of Western Texas and Colorado. I have no doubt there are numerous other physicians similarly situated, whose testimony would be the same. Then, there are a still larger number not quite so favorably situated, it is true, yet sufficiently so to produce valid testimony on this question. I have been doing a country practice for nearly twenty-nine years, and, although typhoid fever has not been very prevalent in my neighborhood, I have had one or more cases almost every year, widely separated from each other and no communication between them, no antecedent case in the neighborhood, and no other case in the family or neighborhood followed those cases. This looks like strong evidence in favor of its spontaneous origin. It prevails sometimes in certain localities as an epidemic, just as dysentery, cerebro-spinal meningitis, and other diseases do; then it will be absent from those localities for five, ten, or fifteen years before it appears again. Then, in other neighborhoods, we only have a few sporadic cases, widely separated from each other, in families who have remained at home, and have not seen any one who has even been with a case of typhoid fever.

J. G. KNOX, A.B., M.D.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from December 6, 1885, to December 12, 1885.

BIRMINGHAM, H. P., First Lieutenant and Assistant Surgeon. Ordered for duty at Camp Grant, Riverside Park, New York City. S. O. 256, Department of the East, December 4, 1885.

BUSHNELL, GEO. E., First Lieutenant and Assistant Surgeon. Ordered for duty as Post Surgeon, Fort Preble, Me. S. O. 256, Department of the East, December 4, 1885.

WILSON, WM. J., Captain and Assistant Surgeon. Ordered for duty as Post Surgeon, Plattsburg Barracks, N. Y. S. O. 256, Department of the East, December 4, 1885.

APPEL, D. M., Captain and Assistant Surgeon. Ordered for duty at Jackson Barracks, La. S. O. 256, Department of the East, December 4, 1885.

EVERTS, EDWARD, First Lieutenant and Assistant Surgeon. Ordered from Department of the Columbia to Department of Arizona. S. O. 279, A. G. O., December 5, 1885.

POLHEMUS, A. S., First Lieutenant and Assistant Surgeon. Relieved from duty at Presidio of San Francisco, Cal., and ordered for duty as Post Surgeon at Fort Halleck, Nev., relieving Acting Assistant Surgeon Loren N. Clark, United States Army. S. O. 113, Department of California, November 30, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending December 12, 1885.

LIPPINCOTT, GEORGE C., Passed Assistant Surgeon. Detached from Navy Yard, Washington, and to wait orders.

DEANE, C. W., Passed Assistant Surgeon. Ordered to the United States Receiving Ship Dale, as relief of Passed Assistant Surgeon G. P. Lumsden.

LUMSDEN, G. P., Passed Assistant Surgeon. Ordered to Naval Hospital, Washington.

LOVERING, P. A., Passed Assistant Surgeon. Detached from United States Receiving Ship Wabash, and to wait orders.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 12, 1885 :

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.								
December 12, 1885	1	22	31	1	9	87	5	0
Deaths.								
December 12, 1885	0	5	3	1	3	44	1	0

BOWDICHIA MAJOR.—At a meeting of the Therapeutical Society of Paris M. Petit read a communication concerning a new alkaloid which he had abstracted from the bark of a shrub used in Brazil in the treatment of fevers and of rheumatic and gouty pains. This bark comes in hard, thick fragments of an ochre-yellow color, has a bitter taste, and resembles somewhat yellow cinchona bark. It is taken from a leguminous plant called Bowdichia major, and known by the natives under the name of sebipira guacu, or sucupira. The alkaloid is said to possess narcotic and mydriatic properties.—*Der Fortschritt.*

THE PRESERVATION OF SOLUTIONS FOR HYPODERMIC USE.—At the meeting of the French Association for the Advancement of Science, at Grenoble, M. Limousin explained the method used by him to prevent the decomposition of solutions intended for hypodermic use. He used little pearls of glass of a size sufficient to contain one dose, which were filled so as to exclude all air and then sealed by fusing the open end in the flame of a lamp. When the solution was wanted for use the end was broken with the fingers, and the needle of the syringe inserted through the opening thus made.

COLLECTIVE INVESTIGATION IN RUSSIA.—The Russian members of the Committee for Collective Investigation of Disease, appointed at the International Congress of Copenhagen, have begun their work. They publish a long circular in a recent number of the *Russkaya Medetsina*, setting forth the object of the Committee and explaining the method to be pursued. A list of questions is appended for the guidance of those willing to aid in the work. The first subject proposed for collective investigation is the etiology of rachitis. The members of the Committee are Rauchfuss, of St. Petersburg, and Runeberg, of Helsingfors.

FERRÁN'S LABORATORY.—A correspondent of the London *Times* writes that while Ferrán was in Valencia he used for his laboratory the kitchen of a new and as yet uninhabited house. In this kitchen there was a water-closet, placed against the inner wall as far as possible from the windows, and ventilated into the kitchen through an opening over the door. The house had just been built by a physician of Valencia, who apparently had as much sense of the fitness of things as he had knowledge of sanitary science. The writer adds that the closet was already so foul and choked up that he was unable to discover whether it trapped or not.

HOSPITALS AND THE GENERAL PRACTITIONER.—Speaking of the way in which hospitals take money from the profession, Dr. Hasket Derby says in the *Boston Medical and Surgical Journal:* "A case in point will show the practical working of this state of things, and I would call attention to the fact that what follows is a simple narrative of an actual occurrence. In a New England city, a surgeon eminent for his skill was consulted by a woman from the country, who had a tumor of the breast requiring removal. She was accompanied by her clergyman, who proceeded to make the necessary arrangements on her behalf for the operation. After some inquiry into the patient's circumstances, a fee was named that she declared herself quite able to pay. A boarding-house was engaged, and the day fixed upon. The two left the office, congratulating themselves on having obtained the desired professional skill on terms that met with no objection. Two days later the clergyman appeared alone. 'Doctor,' said he, 'I am come to tell you that we will not have you perform the operation. You are not, however, to infer that we doubt your skill, or are dissatisfied with your fee of $100 ; but Sister Blank has visited the So-and-So Hospital, and there learned that, by taking a room at $25 a week, she can have the operation performed for nothing. She can readily find other uses for the money she would have paid you, and feels it to be her duty to save the amount.'"

EFFECTIVE VACCINATION.—A London paper says that an apothecary of Thorndale had just received a fresh supply of vaccine points, and some of them happened to be exposed to view on his counter. A burly farmer from that neighborhood was in at the time and amused himself by using one of the points as a toothpick, pricking his gums in the operation. It "took" in the most approved style, and the man is now in possession of a mouth that is crowding all the other features of his face out of shape.

FOR SWEATING OF THE FEET.—Vieusse recommends frictions with subnitrate of bismuth in all forms of bromidrosis of the feet. In a few cases, he says, it seems to have no effect in diminishing the secretion, but it always removes the fetid odor.

THE CONTAGIOUSNESS OF TETANUS.—M. Laiger, in a paper read before the Société de Chirurgie of Paris, maintained that tetanus is contagious, and of an epidemic character. M. Ferrier considers that M. Laiger does not distinguish between veterinary and human medical science. Spontaneous tetanus among animals must be admitted. The facts in favor of the contagion of tetanus are often the outcome of careless clinical study. Rose and Billroth admit the contagion of tetanus, but all attempts to inoculate that disease, even those recently made by M. Nocard, have been unsuccessful.—*Brit. Med. Journal.*

THE VACCINE FROM REVACCINATED CHILDREN is of doubtful protective potency, according to the observations of M. Blot, recently reported to the *Academie de Médecine.*

CONNECTION BETWEEN AFFECTIONS OF THE EYE AND SPINAL CURVATURE.—A Polish physician, Dr. Jasinski, has traced a connection between errors of refraction and curvatures of the spine. In thirty-seven cases of curvature, he was able to prove with certainty the previous existence of these or other abnormal conditions in the eyes, such as insufficiency of the internal rectus, astigmatism, asthenopia, etc. Myopia alone, however, does not appear to cause curvature. Unequal vision and insufficiency of the internal recti seems to be most efficient in the production of spinal curvature. Spasm of the accommodation also is capable of producing it. Removal or relief of the eye affection is followed by improvement in the spinal curvature—a troublesome and obstinate class of cases in orthopædic practice.—*Lancet.*

UNION OF FRACTURES IN THE AGED.—Dr. O. N. Bradbury, of Paris Hill, Me., sends us an account of a case of fracture of the femur in a man aged eighty-eight, in which healing took place perfectly. Dr. Bradbury doubtless forgets that this is not unusual, since fractures often heal more quickly in the aged than during middle life. Mr. Erichsen recounts two cases where very perfect union of fractured femurs took place in patients over ninety years of age.

A Curious Monstrosity.—A child was born recently in Naples having a fifth limb, corresponding to the right lower extremity, growing from the region of the false ribs on the left side, near the sternum. There were well-developed male genital organs in the normal situation, and another set, complete in every respect, except that the testicles seemed to be wanting, on the inner side of the thigh of the supernumerary limb. The patellæ were absent, and a fold of skin prevented full extension of the leg. The skin and muscles of the abdominal wall were wanting in the umbilical region, so that the intestinal movements could be distinctly seen beneath the peritoneal covering. The pavilion of the left ear was also double. At last accounts this child was alive and in good health.

How a Doctor Got a Pass.—The pass question has its humorous side. A Chicago road derives some added traffic from a new cemetery started about a year ago, and lately received an application for a trip pass from a prominent physician, who based his request upon the ground that he had "worked up a good business for the graveyard." He got his pass.—*Omaha Republican.*

Microbes, Meteorology, and Disease.—According to the microbic statistics published by M. Miquel in *l'Annuaire du Bureau des Longitudes*, the bacteria dispersed in the atmosphere vary during the different seasons of the year. It is increased by north and east winds. At Montsouris, in a cubic metre of air, there are in winter, 260 bacteria; in spring, 495; in summer, 650; in autumn, 480; giving an annual average of 471. In January, there were 1,830; February, 1,700; March, 3,300; April, 4,330; May, 4,380; October, 3,910; November, 2,760; December, 1,800; throughout the twelvemonth, a monthly average of 3,480. In this part of Paris, the air is comparatively pure. A similar analysis of the atmosphere in the Rue de Rivoli proved the monthly average, throughout the year 1881, to be 6,295; in 1882, 3,435; in 1883, 2,345; in 1884, 1,836. Thus, during the last four years, the average has diminished. At the same time, the mortality from zymotic diseases has been less, although the population of Paris annually increases at the rate of 29 per 1,000. The deaths from typhoid fever, small-pox, scarlet fever, whooping-cough, diphtheria, dysentery, erysipelas, puerperal infection, and infantile enteritis, were, in 1880, 14,080; in 1881, 13,104; in 1882, 13,613; in 1883, 11,598; in 1884, 11,520; giving a decrease in mortality of 18 per 100. In thickly-populated districts, the proportion of microbes in the air is much larger. Sea-side towns, and those situated among mountains, are the freest from bacteria; a closely-packed population aids to engender and develop these organisms. Berne, although the mountain air constantly sweeps through its atmosphere, is by no means free from the presence of bacteria. According to Freudenreich's researches, the monthly average is 580, four times as pure as the air of Paris (2,020), but inferior to that of Montsouris (420). M. Miquel analyzed the air of a room in an old house in the Rue Monge. The analysis was made in the morning, before any door or windows had been opened. In winter, a cubic metre of air contained 45,000 bacteria; in spring, 26,600. The increased proportion in winter is in consequence of not opening the windows so much as in summer. In the wards of the Hôpital de la Pitié, which are ventilated, there are 92,960 bacteria to a cubic metre in winter, and 54,110 in spring. In a new house in the Rue Monge, a cubic metre of air contained, in winter, 3,120 bacteria; in spring, 3,660; in summer, 4,560. The proportion varies according to the hours of day; from twelve to one o'clock, there are 62 bacteria per cubic metre; from two to three o'clock, 102; from three to four, 130; from four to five, 128; from six to seven, 148. The largest proportion occurs at sunset and sunrise. The following gives an idea of the relative purity of different atmospheres: ocean air, 0.6 bacteria per cubic metre; mountain heights, 1; the saloons of vessels, 60; the top of the Pantheon, 200; Park Montsouris (the average of five years), 480; at Berne, 580; Rue de Rivoli, Paris, 3,480; new houses at Paris, 4,500; Paris sewers, 6,000; the laboratory at Montsouris, 7,420; old houses, 36,000; the new Hôtel-Dieu, 40,000; the Hôpital de la Pitié, 79,000.

Yellow Fever Inoculation.—Drs. Rabourgeon and Freire, of Rio de Janeiro, have recently practised inoculation of yellow fever on a number of medical students and over two hundred porters and laborers. Soon after the inoculation symptoms of yellow fever in a mild form appeared and passed away again in two days. None of the inoculated fell a prey to the disease, while many of their unprotected comrades were attacked by the disease and died. Many also of the European ship-captains and sailors on vessels in port were inoculated and remained free from the disease.

Removing the Sisters from the Paris Hospitals.—In an address recently delivered at the Commencement exercises of the École Municipale de la Salpêtrière, M. Bourneville said that eight of the Paris hospitals had been taken from the hands of the religious communities during the past eight years. There remained twelve institutions not yet attacked, which were served by 246 Sisters, and these, the speaker urged, should be at once put under the charge of lay nurses. At the same time, however, he admitted that there was a lack of properly educated lay nurses for the hospitals already in their hands. He said also that the authorities of these institutions knew so little about the management of the sick that they always put ignorant and incompetent nurses on the night service, just at the time when exigencies demanding experience and intelligence to meet them were the most likely to arise. Dr. Bourneville seems to be one of those unfortunate advocates who are constantly bringing up arguments which tell against their own cause. He also made the remarkable assertion that all the hospitals in the United States were in the hands of lay nurses. In view of the result of the recent elections in France, the present would hardly seem to be the most fitting time to renew the agitation against the Sisters of Charity, looking at it merely as a measure of political wisdom.

Diphtheria Statistics.—During the year 1884 there were 705 cases of diphtheria treated in the Hospital Trousseau. Of these 385 died, and 320, or 45.5 per cent., recovered. The mortality of these patients, upon whom tracheotomy was performed, was 73.2 per cent.

Honors for Brown-Séquard.—At the annual public session of the French Institute, held on October 24th, the president, M. Bouguereau, announced that the biennial prize of the institute had been awarded to M. Brown-Séquard. It was a pleasure, he said, to reward the labors of this indefatigable experimenter, and to recognize his work in a branch of science the great aim of which was to relieve human suffering.

Electricity and Dust.—From the *Popular Science News*, November, 1885, we take the following: "Electricity may yet be of important service as a sanitary agent. It is only within a short time that the discovery has been made that a discharge of electric sparks through a dusty atmosphere will cause the dust to settle, and already the fact is beginning to yield results of practical value. In the experiments to which we have referred, a continuous series of sparks were sent through a bell-jar filled with magnesium smoke, and in a very short time the air in the jar was cleared; similarly, when the jar was filled with steam, electrification caused the globules to aggregate into mist and fine rain, which rapidly fell. It soon occurred to a lead-smelter in Wales that, if electricity could do so much in a laboratory experiment, it might be made to do something useful on a large scale. In lead-smelting works the greatest difficulty is to deal in

a satisfactory manner with the lead-fume, or the volatilized lead which passes off from the furnaces. Long condensing flues and chambers are employed; but even with the best arrangements a good deal of lead escapes to poison the atmosphere, and to the loss of the manufacturers. In an English establishment an experiment has been made in the use of electricity for 'settling' the noxious dust. A large wooden flue was constructed out of casks, and fitted with windows at opposite points throughout its length, so that the 'fume' could be readily examined as it passed along. The experimental flue was fitted with dampers in such a manner that it could be filled with the fumes and closed at both ends, or could be used as a branch or loop in the main flues. The electrical machine had one pole connected to the ground, and the other to an arrangement of metallic points placed inside the flue; a stout brass rod, encircled by a glass tube to insulate it, being carried through the top of the flue, and held in the position desired for the discharging-points. A well-insulated copper wire connected this brass rod with the pole of the machine, which, being kept warm and dry in a shed, gave sparks in all weathers of about four inches in length. Various experiments proved that within certain limits, determined by the size of the electrical machine, the more points of discharge, the greater or more rapid the effect produced. The first experiments were made upon the 'fume' in a stagnant state, by filling the experimental flue with the gases from the main, and closing the dampers at each end. Viewed through the windows, the fume had the appearance of a dense fog; but the moment the electric discharge commenced, a whirling movement was observed round the points, and in a very few seconds the foggy matter collected into flakes, which were rapidly deposited on the sides and door of the chamber, and the atmosphere became clear. When the fume was permitted to pass through the temporary flue, with the rapid motion due to the pressure of the furnace gases, no change was witnessed as it passed the windows; but at the outlet it was found that the foggy matter had been agglomerated into flakes, which in calm weather fell to the ground immediately on escaping from the flue. In this case the pressure forced the fume on too rapidly to allow of the effects of the electric discharge being witnessed through the windows; but it was, nevertheless, deemed satisfactory, and the owner of the works determined to adopt the method of attacking the fume by the electrical method.

Gerhardt's Plumbum Causticum.—According to the report of the Medical Society of Würzburg, the best means of removing condylomata is the so-called "plumbum causticum" used by Gerhardt in the Würzburg syphilitic clinic, and which is composed of oxide of lead and potash. This does not penetrate deeply into the tissue, but produces a blackish slough where it is applied. It can, however, be made to destroy a condyloma in a single sitting. It is very useful for warts on the glans penis and vagina, but is not suitable for papillomata of considerable size, which must be subjected to operation.

Strychnine to Prevent Flooding.—Dr. A. Walker writes to the *British Medical Journal*: "In a number of cases, strychnine administered along with iron for a month before labor, has exerted a remarkable influence in preventing *post partum* hemorrhage, where severe flooding has occurred in previous labors."

Scenes at a Free Dispensary.—"The ingenuity," says Dr. H. Derby, in the *Boston Medical and Surgical Journal*, "of those who seek to disguise their resources must have been experienced to be credited. We were once surprised by a handsome legacy from the estate of an old lady, who had for weeks enjoyed the hospitality of the infirmary, and there been relieved of a cataract; an excellent thing for the institution itself, but not calculated to raise the spirits of the surgeon originally in charge of the case. Another free patient, treated for the same disease, was afterward discovered to have been the mayor of a New England town, and a large real-estate owner there at the time of the operation. 'I prefer to see you at your office, Doctor,' said a young man to me once, 'as I get more of your time. But I suppose I might go to the infirmary, as uncle does.' 'Is your uncle a very poor man?' I asked. 'O, Uncle owns a factory.' 'But how does he manage to pass at the infirmary?' 'Uncle's sly,' said the youth, with an exquisite enjoyment of the fact; 'he puts on old clothes and dirties his hands every time he comes down.' A well-known lawyer of this city once emerged from the waiting-room, and sat down in the patient's chair. On being remonstrated with for attempting to impose himself on a charity, he coolly informed me that all he wanted was an examination and opinion, having obtained which he proposed to place himself under private treatment outside. He had evidently thought he would escape recognition. A well-to-do merchant, being similarly detected, informed us that he had been a tax-payer for forty years, and demanded treatment as a right. Finally, one day, a very respectable and well-dressed lady from New Hampshire presented herself for treatment, and disclaiming poverty, was refused an examination. The next patient, evidently in good circumstances, hailed from the same place. So did the four succeeding, all unfit cases for relief. At last it transpired that we were dealing with the members of a cheap excursion, where one of the attractions offered by the enterprising agent had been a free call at the Eye Infirmary."

The Opium Habit in Temperance Towns.—Dr. R. C. Downey, of Caldwell, O., writes us that he has been much astonished at the large sales of opium and morphine in small towns. He lives in a place of 1,500 inhabitants. He writes: "I called at one of our two drug stores for a drachm of morphine. The druggist said he was out of it. I asked, 'What has become of the large amount you had only a few days ago.' He replied that his regular customers had taken it all. He declined to tell me who they were, but said he had one customer who bought it by the ounce." Dr. Downey thinks that he has obtained facts which show that opium-eating is more common in temperance towns and communities than in those in which the liberal use of alcoholic drinks is allowed.

Arsenical Wall-papers Utilized.—Mr. Matthieu Williams has suggested that the arsenical wall-papers, which are generally regarded as detrimental to health in ordinary localities, may be useful as a protection against the dangers of regions subject to malaria. In a recent number of the *Gentleman's Magazine* he says: "I maintain that the hotels in the vicinity of the Campagna, the Pontine Marshes, the Maremma, and other malarious regions of Italy, should be papered throughout with brilliant green arsenical papers, and painted with Scheele's green or other arsenical pigment. The same should be done in New Orleans and all other such places, for the special benefit of non-acclimatized visitors."

Throat "Comforts."—The following is taken from Davis on the Voice, and is given to show the peculiarities of some singers in their attempt to give a finishing touch to improve the quality of the voice. With many who follow the stage but little judgment is exercised in the selection of "throat helps," as the following quotations prove: "Southeim takes a pinch of snuff and a glass of lemonade between acts. Niemann sips champagne. Tichatcheck washes his throat with mulled claret. Ferenczy, the tenor, smokes a few cigars. Braun Brini drinks a glass of beer at the conclusion of the first act; after the second act, a little moistened bread; after the third and fourth acts drinks *café au lait*; and when she is going to sing the great duet in the fourth act of

'The Huguenots,' as goddess of the art of song, she demands a bottle of Moet Rose as a libation. Cruvelli takes a mixture of claret and champagne. Nilsson takes a glass of beer. Madame Borghi Mamo is lost without a pinch of snuff. Malibran used to take supper in her box about half an hour before coming on the stage. She ate mutton cutlets in the costume of *Desdemona*, and almost invariably washed them down with half a bottle of sauterne. This was generally followed by smoking a cigarette, which was only tossed aside just before her appearance on the stage. These 'fancies' are not recommended. The opinion of most voice-users that I have met is that those who employed them could sing and speak well in spite of the bad effects of these 'congesting' agencies. The course pursued by the following singers and speakers is recommended: Labatt, the Swedish tenor, is in the habit of eating a couple of salted cucumbers before appearing on the stage. He looks upon this as a strengthening remedy for the voice. Wachtel, the tenor, takes an egg beaten up with a little sugar. He considers that this softens the voice, and is, no doubt, very good. Madame Sonntag used to take sardines between acts. Madame Desparee soothes her throat with plain warm water. Madame Cabel eats pears. Adelina Patti prefers a bottle of seltzer water. Ugaldi has a preference for plums. Trevelli Bettini eats strawberries. One of my patients, a noted star actor, takes a cup of warm coffee with cream and sugar, and a warm boiled potato with a little salt, between acts. The following is the experience of an old amateur of New York City: 'It appears rational to avoid anything before singing that would tend to irritate the throat.'"

A Strong Argument in Favor of Vaccination.—Dr. W. T. Clute, of Schenectady, N. Y., sends the following interesting item: "Having read an editorial in the issue of The Medical Record for November 21, 1885, title, 'A Strong Argument in Favor of Vaccination,' allow me to add another case to the list in support of the argument. My own mother, now in her fifty-sixth year, had the small-pox while an infant in arms. Last September she allowed me to vaccinate her, just to see if it would take. To the surprise of both of us, it took and ran through a typical course. The vaccine used was a fresh bovine ivory point. It must have been nearly fifty-five years ago since she had the small-pox. She always expressed herself as ready and willing to attend any of her friends should they be unfortunate enough to be smitten with the small-pox, feeling sure that she was safe from an attack. She now thinks she would have taken the disease a second time, and that the vaccination will give her even better protection than the small-pox itself."

Dr. D. J. Cain, Asheville, N. C., also writes on the same subject as follows: "In an editorial in the issue of The Medical Record, November 21st, you say: 'We have been somewhat surprised to find that vaccination "takes" with those who have had small-pox, two or three such cases having come under notice. . . . Moreover, that vaccination is a surer safeguard from small-pox than small-pox itself.' As bearing upon these statements, in confirmation of the one and partial disproof of the other, I relate the following case which came under my notice many years ago: In 1839 a girl about eighteen years of age, with confluent variola, was admitted to the Hôtel Dieu, Paris, in the service of M. Chomel. She passed safely through the disease, and when she was well it occurred to M. Chomel to test the receptivity of the system for vaccinia. He vaccinated her with humanized virus, which 'took' properly; the vesicle being of the primary form. She was then discharged. Three months later she was admitted to the same ward with a second attack of confluent variola. Through this she likewise passed safely. The susceptibility of this disease possessed by this woman is paralleled by that of the woman reported by Dr. Gregory, of Edinburgh, who had confluent small-pox *nine* times, and died in the ninth attack."

Eruptions Due to the Use of Certain Medicines.—Quinine: Erythema scarlatina; papular erythema (Kohner); hemorrhages and purpura; pemphigus, œdema, and prurigo. Cinchona, Belladonna, Stramonium, Strychnine, have the same characters as quinine. Digitalis: Erythema after long use (Traube). Aconite: Vesicular exanthemata. Santonine: Pemphigus, vesicles (Deschamps). Opium and Morphine: Erythema (Apolan); papular eruption, with marked desquamation and itching. Pilocarpine: Increased perspiration. Atropia: Diminished perspiration. Phosphorus: Purpura. Mercury (internally): Erythema (Kalus, Zaissi, Gamberini); eczema (Aley, Fournier, Gamberini). Arsenic: Erythema and papules (Imberts-Goubayre); vesicles and pustules (Bazin, Raymondi, Gamberini). Carbolic Acid: Erythema (Taourschi); pemphigus (Zaissi). Salicylic Acid: Purpura (Freudenburg); vesicular angina, pemphigus. Chloral: Erythema, slightly colored, itching, desquamation; purpura and petechia (Crichton and Brown); eczema (Kirn). Copaiba, Cubebs, Turpentine: Pemphigus, erythema, eczema (Renter). Cod-liver Oil: Acne. Iodide of Potassium: Papules, vesicles (Bumstead, Gamberini); pustules, ecthyma, eczema (Landrieux); ecchymoses and purpura (Tilbury Fox). Bromide of Potash: Papules and pustules, deep tubercles with ecchymoses, pemphigus, ulcers.—*Translated by Dr. C. E. Warren in College and Clinical Record.*

Treatment of Carcinoma of the Womb.—After scraping away as thoroughly as possible a medullary carcinoma from the cavity of the womb, Professor Parvin applied this caustic: ℞. Bromi, ʒj.; Acid. carbolici, ʒiv.; Iodi, ʒij.; Alcoholis, fʒj.—M.

Accidental Cardicentesis.—Dr. H. H. D. Moorman, of Dalton, Mo., sends a report of a case of this nature which he met with in his practice recently. The patient, a negro, twenty-two years of age, had suffered from repeated attacks of rheumatism, and when first visited was found to have a mitral regurgitant murmur, with slight enlargement of the heart. During the fifth week of his illness he was rather suddenly seized with a pain in the region of the heart, and suffered intensely from dyspnœa. "The precordial region was excessively sensitive to pressure, so that very little information could be obtained by percussion. Even the ear or stethoscope applied to the chest-wall caused such an increase of pain and dyspnœa that a satisfactory physical examination was an impossibility. Very naturally I referred both pain and dyspnœa to pericarditis, and as the dyspnœa increased progressively, I inferred that effusion was taking place. On the fifth day of the attack I again attempted a physical examination, and thought I made out an increased area of precordial dulness. As the dyspnœa seemed to threaten life, I concluded to aspirate the pericardial sac, and proceeded to do so on the seventh day of the attack. Dr. G. M. Dewer, of Keytesville, Mo., was present. I introduced a medium-sized aspirating needle in the fifth intercostal space, midway between the nipple line and the outer margin of the sternum. The point of the needle was directed slightly upward, and introduced to a depth of about two and a half or three inches. Upon turning the stopcock venous blood was seen to be running through the tube, and the needle was vibrating in the same manner as observed in the familiar dart-and-flag experiment performed by physiologists. Of course the needle was instantly withdrawn. About two drachms of blood had escaped, without producing any disturbance so far as could be observed. No adventitious sounds were heard afterward over the region of the puncture. The patient slowly recovered from his rheumatism—all symptoms disappearing or being modified. At the present time he suffers slightly from dyspnœa, has his old mitral regurgitant murmur, and the heart is slightly enlarged." Dr. Moorman was led to report this case from reading the article on "Cardiac Aspiration," in The Record of November 14th.

CYSTIC KIDNEYS WITH LARGE BILATERAL PERINEPHRITIC CYSTS.[1]

BY T. MITCHELL PRUDDEN, M.D.,

NEW YORK.

THE patient, a woman forty-seven years of age, corpulent, and with pale, sallow complexion, had suffered for sixteen months from meno- and metrorrhagia. Three months before death she had abdominal pain; the legs were œdematous. The vagina and cervix were of cartilaginous hardness, and the vagina so much contracted as scarcely to admit the examining finger. At this time the hemorrhages had entirely ceased. A diagnosis of malignant growth of cervix and vagina was made, supposed to be scirrhous carcinoma.

She continued to suffer from severe abdominal pain, especially referred to the right hypochondriac region, and with shortness of breath. Area of hepatic dulness apparently reached to umbilicus. Ascites slight. Œdema of subcutaneous tissue of abdomen excessive. Urine contains no albumen. Microscopical examination was not made.

At the autopsy the liver was found to be small and pressed upward by a cystic-looking tumor which occupied a large part of the right side of the abdomen, and was adherent to the mesentery and coils of small intestines. During its removal it was accidentally ruptured, and about one litre of bloody fluid containing flocculi of lymph was emptied. This cyst contained the right kidney. On the left side the same condition was found, except that the cyst was smaller. Both ureters were considerably dilated. Owing to the peculiar circumstances under which the autopsy was made, the lower part of the uterus and the vagina were not examined.

The cyst around the left kidney, which was intact, was found, when opened, to contain about three hundred cubic centimetres of transparent, yellowish, gelatinous material through which strings and flocculi of fibrin are scattered, and from which on removal from the sac clear yellowish fluid oozes. The cyst is 20 ctm. long and 11 ctm. wide. It contains, aside from this gelatinous material, in its posterior portion, the left kidney. The cyst wall is composed of dense connective-tissue, which in its outer layers contains a varying quantity of fat, and is from .5 to 1.5 mm. in thickness. Its inner surface is smooth, is covered with a thick pellicle of fibrin, and presents no internal cellular lining. This cyst-wall is attached to the kidney along its pelvic edge and along the convexity, so that the anterior surface of the kidney forms a part of the posterior cyst-wall. The kidney is 15 ctm. long, 9 ctm. broad, and about 4 ctm. thick. The posterior surface of this kidney is covered by a thick, dense connective-tissue investment which appears to consist of the thickened capsule of the kidney, rather loosely joined to the membrane, which passing forward forms the anterior portion of the above-described cyst-wall. On stripping the thickened capsule from the posterior surface of this kidney, it leaves a slightly nodular but in general rather smooth surface, on which three or four small cysts are seen, the largest about three millimetres in diameter.

The anterior surface of this kidney, which forms a part of the posterior wall of the large cyst, is thickly studded with small cysts, varying in diameter from one to thirteen millimetres. These are flattened, lie close beneath the capsule, and contain a transparent gelatinous material, similar in appearance to that with which the large cyst is filled. Over these small cysts the capsule is very thin, but between them it is thickened, in places, to nearly one millimetre. The capsule near these small cysts is, in places, of an orange color. A large, dilated blood-vessel, filled with a blood clot, projects from this free surface. On meridional section through this kidney the cortex is found thickened (in most places one centimetre thick); the markings are indistinct, and the whole appears as if not well preserved. (The specimen had been for some time in dilute alcohol.) The pelvis and calyces are dilated so that they would hold about from twenty to thirty centimetres of fluid. The mucous membrane of the pelvis presents no trace of inflammation.

The cyst inclosing the right kidney, which had been opened before it came into the hands of the writer, was about twenty-four centimetres long, sixteen centimetres wide, and nearly completely inclosed the kidney, being attached to it along its pelvic border. At the upper part of the kidney, anteriorly, a small opening led into another cyst similar to the large one, and forming a part of the complete cystic investment of the organ, which measured about seven centimetres in diameter. The wall of these large perinephritic cysts was similar to that on the other side, but in places was somewhat thicker. The surface of the kidney on both sides was studded with small, flat cysts, containing gelatinous material similar to those in the other kidney.

Microscopically the posterior portion of the left kidney showed a considerable increase in the interstitial connective-tissue. In other parts of both kidneys the interstitial tissue was but slightly increased in amount.

There was apparently swelling of the epithelium of the tubules, but the poor preservation of the specimen would not permit of a definite conclusion as to epithelial changes.

In the cortical portion, especially of the left kidney, close beneath the capsule, and scattered among apparently normal tubules, are found dilated convoluted tubules, with flattened epithelium, which are filled with gelatinous material, looking under the microscope somewhat like very soft mucous tissues (see Fig. 1). Near these, in the cortex, as well as in the thickened capsule, are small rounded cavities without a distinct cellular lining, which was filled with the same gelatinous materials (see Fig. 2). Between these simply dilated tubules and microscopic cysts and the larger cysts beneath and in the capsule on the surface of the kidneys (see Fig. 3) all intermediate forms are to be found.

The small cysts beneath and in the capsule, as well as the enormous cysts inclosing both kidneys, contain the same gelatinous material, which presents the same microscopical appearances as the above-described dilated tubules and the tiny cysts near them.

The orange color of the capsule near the small cysts is due to crystals of hæmatoidin.

Résumé.—We have thus two large kidneys with dilated

[1] The following case was reported, and the specimens presented, to the New York Pathological Society by Dr. H. J. Boldt, in behalf of Dr. Samuel Kohn, candidate for membership. The specimens were referred to Dr. Prudden for examination, and the following is his report, together with an abstract of the history as furnished by the candidate.—Wesley M. Carpenter, Secretary.

pelvis, calyces, and ureters, in a condition of chronic diffuse nephritis, and with the exception of the posterior surface of the left kidney, thickly bestrewn with small superficial intra- and subcapsular cysts containing material of gelatinous appearance. Thus far the organs present a lesion which in degree and kind is not unusual. But in

FIG. 1.—Dilated tubules filled with gelatinous material in cortex of kidney (left), × about 200.

addition to this both kidneys are lying, one with one, the other with both surfaces free, in the cavities of large inclosing cysts, which have a capacity respectively of about three hundred and one thousand cubic centimetres. One of these cysts, the larger, contains bloody fluid, fibrin, and gelatinous material, the other gelatinous material, clear fluid, and fibrin. Both kidneys are covered with a connective-tissue capsule which is thicker than normal, while the walls of the inclosing cysts are thicker than the capsules themselves.

Macroscopical and microscopical examination shows numerous intermediate stages between tubules simply dilated with gelatinous material of definite microscopical appearance, like small intra- and subcapsular cysts, and the large perinephritic cysts themselves.

Although in a lesion as old and extensive as this, it would be unwise to assert with great positiveness the exact mode of origin of these large perinephritic cysts; the date above furnished would seem to the writer to justify the conjecture that the process commenced as an ordinary bilateral cystic kidney, associated, as is often the case, with chronic diffuse nephritis. But while most of these cysts remained small, others increased in size, and working their way between the layers of the capsule

FIG. 2.—Small cyst filled with gelatinous material in cortex of left kidney, × about 200.

of the kidney produced the large inclosing cysts. The walls of these cysts are so thick that we must assume that hand in hand with the accumulation of the gelatinous material there occurred, as is frequently the case during the accumulation of adventitious material in various parts of the body, a thickening of the connective-tissue which formed the cyst wall. Whether the outer cyst capsule was formed by a splitting up of the kidney capsule, or from the connective-tissue of the fat capsule, or from both, it would be difficult or impossible to say.

Whether the kidneys were originally the ordinary congenital cystic kidneys or not, it would also be impossible to decide. The above-described intermediary forms between the larger and the smaller cysts would indicate that the process was progressive at the time of death. Furthermore, some of the small cysts in the kidney capsule have rather the appearance of cysts of mucous softening than of dilated tubules; but still, even if this were the case, they might have originated in the latter.

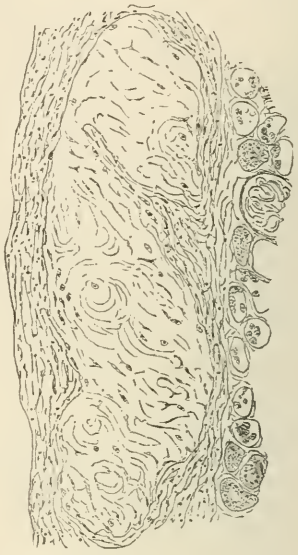

FIG. 3.—Section of the subcapsular cysts, × about 80.

It is a striking fact that the outside of the kidneys (posterior of the left) which is not involved in the large inclosing cysts at all, is the one which shows almost no small intra- and subcapsular cysts, and beneath which there is much new-formed interstitial tissue.

In the absence of a definite knowledge of the condition of the pelvic organs, it is impossible to decide whether the factors which induced the dilatation of both ureters and pelvis could have contributed to the development of the cysts; but it seems probable to the writer that they had nothing to do with it.

The writer has been unable to find any similar recorded case.

THE CONTAGIOUSNESS OF LEPROSY.—Although most authorities are in accord in the belief that leprosy is not contagious, yet there are some who claim that the disease may be communicated by contact. In a discussion held not long ago, before the Academy of Medicine of Paris, M. Vidal upheld the theory of contagiousness, but his views were controverted by Hardy, Dujardin-Beaumetz, Leroy de Méricourt, and others. Dr. Zambaco, of Constantinople, the physician to the Miskin Hané, the most notable lazaretto in Europe, is a strong non-contagionist. He asserts that he has never known a case of the disease to have been acquired by communication with a leper, although the patients of the Miskin Hané are visited by their relatives and friends without any restrictions. Heredity, he believes, is an important factor in the etiology of the disease.

A LARGE TUMOR.—M. Terrillon recently removed from a man, thirty-five years of age, a lipoma weighing fifty-five pounds. It was attached to the mesentery, and the incision necessary for its removal extended from the pubis a distance of twenty-two inches, nearly to the xyphoid appendix. Eight days after the operation the patient was reported to be in good condition, with every chance for a perfect recovery.

A MODIFICATION OF FÖRSTER'S METHOD OF ARTIFICIALLY RIPENING CATARACT.

By THOMAS R. POOLEY, M.D.,
NEW YORK.

THE fact, now well known to those who have used cocaine in operations upon the eye, that the aqueous humor escapes very slowly after puncture or incision of the anterior chamber, led me to consider whether its use would not enable us to perform the operation suggested by Förster without an iridectomy.

The obstacle against such a procedure as proposed by him, without first making a large iridectomy, is obvious. The lens, after the escape of the aqueous humor, will fall forward and come in contact with the cornea; unless the iris has been removed or the pupil is kept widely dilated during the next step of the operation, which consists in rubbing the cornea over the exposed surface of the lens, the iris will be injured. This is accomplished by the use of cocaine. If the pupil be first fully dilated by atropine, the subsequent use of cocaine will prevent it, by the slow escape of the aqueous, from at once contracting. That such a method of operating might be resorted to, has already been suggested, but, so far as I know, not yet attempted.

Candron, in an article on the artificial maturation of cataract (*Rev. gén. d'Ophth.*, 1883, No. 6), says, at the conclusion of his paper, that the maturation of the cataract, when we intend to extract without preliminary iridectomy, may be done by making paracentesis of the cornea, letting the aqueous escape, when the lens would fall forward upon the cornea, after which the lens could be triturated from without. In order, therefore, to determine whether an immature cataract can be matured in this manner, I resorted to the following experiments on a rabbit's eye. As it was very difficult, if not impossible, to procure a rabbit with an immature cataract, my first experiment was to see whether a healthy, transparent lens could be rendered cataractous by this method.

The operation was done in the following way: First the pupil was dilated to its utmost extent with atropine, then, from three to five minutes before operating, a few drops of a four per cent. solution of cocaine put in the eye. Paracentesis of the cornea was then made with a broad needle, taking care not to wound the lens capsule. The needle was then slowly withdrawn, allowing the aqueous to escape slowly. Trituration of the cornea was now made in a circular manner, the escape of the aqueous thus completed, and the collapsed cornea came in contact with the lens. The pupil remained moderately wide throughout this procedure and then slowly contracted. Atropine was now instilled, and the animal put in a barrel in which some clean straw had been placed. No attempt was made to close the eye in any way. The following day the pupil was contracted, but there was beginning opacity of the lens. By the vigorous use of atropine the pupil became wide, and the lens, which was well seen now, showed very decided opacity, most marked in the anterior cortical layer. The lens seemed to reach its maximum of opacity in from two to three weeks, but did not become complete, but showed a mottled, mother-of-pearl appearance, with opaque and clear setons (immature cataract). The ophthalmoscopic image was not shut off. The operation was therefore repeated on the same eye, April 12, 1885, and executed exactly in the same manner as the first. Immediately following the operation the opacification of the lens was more marked, and in the course of from three to four weeks the cataract was complete, so that the entire lens was opaque, and ophthalmoscopic view of the fundus no longer possible (mature soft cataract).

There was no inflammatory reaction following either of the operations, although after both the lens was considerably swollen, as shown by the narrow anterior chamber from bulging of the iris. It required, too, for the first few days rather active use of atropine to maintain dilatation of the pupil, which, a few days later, would remain wide enough from a single instillation once in twenty-four hours. At no time during the formation of the cataract did the animal seem to suffer any pain. It was only confined to the barrel for a few days after each operation, and the rest of the time allowed the liberty of the back yard. From these experiments, then, it seems to be proven that an operation for the maturation of cataract may be successfully done without any great risk of danger, without making an iridectomy. I have not, as yet, ventured to perform it on a patient. Nor do I feel sure, as yet, that further experience or observation will commend the method. I only communicate the result of my experiments for the purpose of giving my experience to the profession, leaving the future and the accumulated experience of my colleagues to decide whether the proposed modification shall be adopted.

MEDICO-LEGAL CASES.

By HENRY A. RILEY, ESQ.,
NEW YORK.

THERE was a famous case in New York, quite a number of years since, where a druggist in a country town gave out belladonna instead of extract of dandelion, in preparing a prescription. The wholesale manufacturer was the one who had made the original mistake, and the country druggist did nothing more than give out what had been placed in his hands as a harmless drug, when in reality it was a poison in the quantity used. The question at issue was whether the manufacturer or the dispenser was liable, and the court held that the former was. The same drugs now appear in an Iowa case, where the same mistake was made. The circumstances were unusual, and in some degree amusing. The druggist was preparing the prescription, when the customer helped himself to a dose from the jar. The druggist saw him take it, and the effect upon him stopped the further preparation of the prescription. The customer soon afterward sued the apothecary for damages. The answer interposed was to the effect that the customer was a trespasser in trying to help himself from the jar, and that if he suffered from so doing it was his own fault. The merits of this defence came up for consideration, and the court decided that it would not avail the apothecary. It was stated that as the customer took the dose with the knowledge of the apothecary, it would be under an implied promise to pay if asked to, and this negatived the idea of a trespass. The two persons were acquaintances, and the custom of "helping" one's self to drugs or goods is not an uncommon one in country stores. The apothecary therefore had to pay for the mistake of having belladonna in a jar supposed to contain extract of dandelion. The two drugs are much alike, but it will be a satisfaction to the public to be able to feel that the apothecary is bound to know what he is doing when he handles a dangerous article.

There are two projects of compulsory legislation in New York interesting to physicians. One of them is a bill making vaccination imperative, and this subject was recently discussed by the Society of Medical Jurisprudence in this city. It was the general opinion, however, that a law would not be wise now, and that the true policy was to make the public better acquainted with the merits of vaccination. On this point, it was stated by Dr. Taylor, of the Board of Health of New York City, that the opposition among people in the poorer districts was much less that it had been.

The other project is a bill providing that the bodies of all persons dying of contagious or infectious diseases shall be disposed of by cremation. The arguments in favor of such a law are hard to meet, but the attempt to put it upon the statute book would be very likely to stir up opposition to cremation in any case. As it is now, cremation is making wonderful progress in popular favor,

but nevertheless the vast majority of people still believe in earth burial, and will for generations to come, perhaps forever.

The great and increasing use made by manufacturing companies of the water-power furnished by running streams and the necessity of throwing refuse matter into the streams, which are thereby injured for drinking purposes, is an important question frequently calling for determination in the courts.

A recent decision in a Maine court, while not raising the question of injury for drinking purposes, involves the same principle, and will be of interest.

The Kennebec River, in Maine, has numerous dams which give water-power to a large number of mills of a great variety of industries. Some of these near Waterville are cotton mills, and the refuse thrown into the river by the lumbering mills some miles above gets into the race-ways, clogs the wheels, and frequently compels a stoppage of the entire mill until the matter can be cleared away. A very large amount of capital is employed in both branches of industry, and the mills have been established for years. The question now arises whether the cotton mills have such a right to the free use of the river water that they can compel the lumber mills by injunction to stop throwing refuse material, shavings, edgings, sawdust, etc., into the stream. The lumber-mill proprietors say that there is no other way to do but to let the water carry off the refuse, and that to be obliged to adopt some other means of getting rid of it would be so expensive as to render the mills worthless. The cotton-mill proprietors say that they cannot carry on their business without loss unless the practice is stopped. It will be seen that the question is a very important one, and involves the right to throw matter into a stream which may make it unhealthy to those using it for drinking. The court considered the case very carefully, and a large number of lawyers were employed on both sides. The decision, which has now been rendered by the highest court in the State, holds that the lumber mills cannot be permitted to throw refuse matter into the stream, and orders an injunction to issue against everything except common sawdust. The lumber mills were allowed, however, four months' time to arrange for some method of disposing of the waste material before the injunction should issue.

An interesting question in the law of *habeas corpus* was brought up in the case of Surgeon-General Wales, who, during the proceedings at Washington in his case, was ordered by the Secretary of the Navy to remain within the bounds of the city of Washington. The medical director thereupon secured a writ of *habeas corpus* to test the question of his lawful detention within the city limits. The granting of this writ came before the Supreme Court, and it was there held that the famous writ only applied to those persons actually imprisoned, and was a safeguard against unlawful imprisonment. Surgeon-General Wales was only under moral duress through the order of the Secretary of the Navy, and could have disobeyed if he had so desired. It was therefore decided that he had no right to have the writ issue in his favor.

The Abuse of the Present Dispensary System.—Dr. W. H. Haynes, of this city, writes: "As I understand it, the present dispensary system arose in this manner: Years ago each doctor was in the habit of appropriating a portion of his time, skill, and remedies to the treatment of poor people without charge. Later on the generous public took the burden of providing a proper place and medicines off their hands, and concentrated the labor in the hands of a comparatively few younger members of the profession, who gladly assumed the burden for the benefit they received in experience and income. This arrangement proved satisfactory till within the last few (ten) years, when abuses have arisen in consequence of increase in the number and in the attendance of improper subjects at these charitable institutions; so that now, besides the recognized general dispensaries, we have life insurance companies, beneficial organizations, and druggists carrying on such an institution in a modified way, as a legitimate branch of their business, aided by medical men who, not being able to make a living in the legitimate manner, are compelled to take these appointments in self-defence, to gain a maintenance by the advertisement and income they offer; of course, to the detriment of their brethren who are not so fortunate, or deem it unworthy, and, therefore, the ones to suffer. Now, this condition of affairs has been brought about as much by the profession itself as by the public, the former becoming too numerous, and the latter, except where a selfish motive is evident, too generous as regards this form of charity. Therefore it seems to me that the remedies must be applied to both these circumstances, and applied the same in both instances, viz., limitation in the first place of the number of men, and in the other the generosity of the public from providing any more such institutions, by law and education. In the meantime there is no better method of partially limiting the above than through the labors of the Charity Organization Society, but the main remedy lies with the profession itself, by raising the moral tone of their own body through the methods indicated."

The First Bacteriologist.—In the year 1726 a quack, Boïle by name, made his appearance in Paris, and promulgated a new theory of disease. All maladies, he said, were due to the presence of animalcules in the tissues, and all that was necessary to effect a cure was to introduce other and stronger animalcules which would destroy the disease-producers. He had, he claimed, a large supply of the superior and curative animalcules, and would dispose of a sufficient number of them to any one who stood in need of their services and would pay for them. Of course he found plenty of customers, and soon drove a thriving business. But he came to grief. He used to demonstrate under a magnifying glass the action of his remedies. He would take a little blood from the patient, and, putting it under the microscope, would exhibit to his awestruck visitors a number of hideous forms which were the cause of the malady. Then he added a drop of his special culture and away would go the wicked animalcules, leaving the field clear. Some incredulous fellow, however, examined into the matter a little too minutely, and discovered that the microscope had a false bottom and that the battle of the animalcules was nothing but a painted show. This discovery had the same effect upon M. Boïle that his remedy had upon the germs—he disappeared with amazing celerity.

Pyridine in the Treatment of Asthma.—Dr. Neff has used, with perfect success, the new drug pyridine in the treatment of the paroxysms of *asthma* in six different cases, independently of the cause, whether bronchial, cardiac, or renal. It seemed not only to relieve the paroxysm, but also to prevent the return in a measure. As the remedy is so very irritating to all the mucous membranes, the following method is used in its administration: The patient being placed in a small room, from thirty to forty drops of the drug are put on a plate and placed at a little distance from the patient. This may be repeated if necessary, and the inhalations kept up from five to thirty minutes, but relief usually is obtained in from one to five minutes.—*College and Clinic Record.*

Veterinary Surgery.—Mr. Snarry, a veterinary surgeon, has accomplished a novel feat in the way of surgery. A cow on the Westow Grange Farm, near York, broke its leg, and there being no chance of reducing the fracture, the limb was amputated, and Mr. Snarry tried the experiment of affixing a wooden leg. This has been found to answer admirably, and the cow may be seen grazing with a calf by her side.—*Provincial Medical Journal.*

CONTROLLING SEX IN GENERATION.

WE are loth, most of us, to accept new theories concerning any vital phenomena. Such acceptance involves a rude disturbance of our mental ease, and we hesitate to bestir ourselves, particularly as we do not know whither our steps may lead us. If any new theory is to be entertained its logical conclusions necessarily enforce themselves, though we may not at first see their relations to previously existing facts. Often our first ventures are hindered by our recollection that the promulgators of new theories have very biased views. Collateral proof strengthens us, particularly when it comes from one approaching the subject from a standpoint which differs from that of the original champion of the new idea. An illustration of this fact is found in the recent publication, by a layman, of a volume with the title, "Controlling Sex in Generation."

The author is Mr. Terry, whose residence is not given. The publishers are a well-known firm in this city. To anticipate, the conclusions reached in regard to the subject are identical with those obtained some time since by scientific observers, viz., "That at the generation of male offspring the mother must be in a higher degree of sexual excitement than the father. And, reversely, at the generation of female offspring the father must be in a higher state of such excitement than the mother." The value contributed by this particular volume to the question lies (as we have indicated) in the fact that its author is an intelligent layman, who writes in a spirit of candor, and who presumably is free from the many tendencies to one-sided opinions which encompass purely scientific men.

The writer has been, according to his preface, a husband and father for over thirty years. His first five children were all girls. A natural desire for sons led him to look into the subject of origin of sex, and to collect and collate facts bearing thereon. From these facts he adduced the theory we have stated. Experiments with some farm stock confirmed it to his own mind. This physical law, he frankly tells us, he has put in practice in his own marital relations, with the result that of the last four children born to him, three were boys.

He regards the subject as one of importance, in view of the existing and increasing excess of females over males in all the fully-settled portions of our country. He argues that this is partly owing to the gradual decline in the strength of mothers, taking them as a class. This decline has three material indications: the first is shown in the proportionally increased number of deaths of boys in early infancy from debility, marasmus, etc.; the second in the increased proportion of boys among the still-born children; the third in the decrease in the conception of boys. These facts are illustrated in extensive and carefully prepared statistical tables, compiled from the mortality records of some of our largest cities and states. The relative mortality of boys to that of girls is, in still-births 100 to about 68; in brain diseases, 100 to 82; in diseases indicating feeble vitality (debility, marasmus, etc.), 100 to 85; the same ratio holds true in diseases of the respiratory organs; in diseases of the nutritive organs, 100 to 91; contagious diseases he finds about equally fatal in both sexes. From the study of the lower forms of life he advances to the assumption that any physical law governing sex operates either before or at the moment of conception or impregnation, and not afterward.

The natural sequence follows that in order for parents to have male offspring, it is necessary for them to put themselves under those conditions wherein this physical law may act. Inasmuch as most of our women in modern civilized life are physiologically below par, every favorable circumstance of environment ought to be brought to bear upon them. Fashionable follies should be shunned. In the large and influential class of women who avoid these—the class known as the religious world—the desires connected with maternity should receive a higher respect; a holier and less sensual idea should be accorded to the fulfilment of the maternal duty. Physical debility in the wife renders proportionally stronger the sexual impress of the husband. Under the operation of the law female children result. The more sickly the wife, the more debilitated the children. Says the author: "There was never yet a right-minded wife who would not be proud to be surrounded with a round dozen of stalwart, clear-headed sons and rosy-cheeked daughters; but when they come forth pale, stunted, scrofulous, and spine-distorted, fit only for the physician's hands, one or two quite suffice to satisfy the mother's pride."

The conclusion drawn as the final one is, that given a wife in average health desiring male offspring, she should carefully observe her disposition in regard to sexual desire with reference to the days following menstruation, and the time when this disposition is felt most strongly should be chosen for the performance of the marital function.

In the experience of the author it is noteworthy that all three of the male children born to him died in infancy, not one surviving till the birth of the next. The remaining child of the four was born intermediate between the second and third son. She suffered the usual run of infantile diseases (some of them being more severe, seemingly, in their attack, than were those that carried off the male children), and grew up to be a robust child. The author observes that women who bear preferably female offspring are often deficient in milk for males, if such are born to them. He thence argues that wet-nurses are more necessary for males.

The wonderful influence which brings the sexes together in reproduction he regards as a sort of animal electricity—

the male being the positive and the female the negative element. He adduces the alkalinity of the semen and the acidity of the menstrual fluid (asserted by some) as analogous in reaction to the behavior of certain chemical bodies when subject to disintegration by electrolysis.

We have, in the foregoing, outlined the main features of the volume. Many interesting points have not been touched upon. The author's lucid style and logical method show him to be no shallow observer of sociological and biological facts. He claims that the large surplus of women in the community is now the cause of many social evils as well as moral ones. Hence he feels "no doubt as to the propriety of publishing to the world a modest theory that professes to show how this relative disproportion of the sexes originates, and how the equilibrium can be restored" He asks for a careful examination of his theory before it is condemned. He claims to be actuated by a desire to do good, and asserts his honest belief in the truth of the theory advanced. In any event, the book is valuable as the contribution of a conscientious, intelligent layman to the solution of a scientific problem.

A CURIOUS MISREPRESENTATION.

The Medical and Surgical Reporter does us extreme injustice, and at the same time informs us of something entirely new. We are told that "THE MEDICAL RECORD is the organ of the New York circle," and that "its great mission has been submerged by an exceedingly unpatriotic course." Our valued contemporary has made an entire mistake, which we feel it will now be the first to correct. THE MEDICAL RECORD is an organ of no circle or clique whatever, but only of the medical profession of the United States. It has always endeavored consistently and earnestly to promote the welfare and elevate the status of the general practitioner. We venture to affirm that no medical journal is in more hearty sympathy with readers of this class all over the country, or receives from them in every State and section so many letters and communications showing an interest in the scientific and social advance of the medical profession. The Organ of a Circle! In the Name of the Prophet, Fudge!

A DANGER IN PUBLIC BATHS.

A CASE is related by Dr. Aubert, in the *Lyons Médical*, No. 35, 1885, of a family in which the father, mother, and little daughter were all suffering from gonorrhœa. The infection of the mother from her husband was evident, but the mode of communication of the disease to the four-year-old girl was not so clear, until the woman mentioned the fact that she had bathed twice since she had noticed the discharge from the vagina and had felt a scalding on passing water, and had taken her little girl into the bath with her. She said that the child had commenced to have a discharge from the vagina three or four days after taking the first bath. Another child in the same family, whom the mother had not taken into the bath, remained free from the disease.

In *Lo Sperimentale*, No. 10, 1885, Dr. Filippi asserts, in commenting upon the above case, that during the past year over fifty little girls acquired vulvitis, and some of them grave ophthalmia, in the free medicated baths of Santa Lucia, in Florence. The contagion was apparently conveyed in the water of the bath, which was limited in quantity and seldom changed.

This danger of acquiring not only specific vaginitis and ophthalmia, but other diseases, through the medium of water which is not constantly renewed, is one which would seem not to have received the attention it deserves. In the summer bath-houses along our river fronts there is a constant flow of water, it is true, but it may be doubted whether even there at slack tide this current is sufficient to carry away all infectious material. But in the winter baths, of which there is quite a number in New York, the water is warmed, and is not always renewed as often as it should be. If the project of some philanthropic individuals of providing free public baths in winter as well as in summer should ever assume definite shape, it would be necessary to consider this danger of infection and to take the proper measures to guard against it.

News of the Week.

CONCERNING THE DISINFECTION OF RAGS.—Mr. Augustine Smith, of this city, Vice-President of the American Paper-Makers' Association, writes: "The medical profession, of which you are a representative, is rightly regarded as the defender of the public against quacks and impostors. The confidence it has so well earned in this direction carries a certain responsibility with it, because it makes it very desirable for quacks to gain the aid of the profession where that can be done. It is in view of this responsibility that I wish to lay before you some facts touching the importation of rags (the raw material of paper) into the port of New York. Under the law of the State, as now interpreted and practised, it is within the discretion of the health officer of New York to forbid the landing of imported rags, no matter whether they be brought from infected districts or not, or whether there be reason to suppose that they are themselves infected or not, unless they are '*disinfected' to his satisfaction*. This is the accepted law and the actual practice at this port, and this extraordinary discretion is subject to no accountability or control except by the Board of Quarantine Commissioners, and in their hands the power of control, as a matter of fact, is not exercised. Now, the manufacturers of paper contend that this practically unchecked and arbitrary power in the health officer is subject to grave abuse, and that it is unnecessary to the protection of the public health. The manufacturers of paper do not wish to import disease. If they had no other reason for not wishing it, it is enough that it would be greatly against their interests to do so; for, as soon as it was known that they had done so, their employees would leave, their mills would be closed, and their importations would be stopped. They have been taught by experience to doubt whether rags can be thoroughly disinfected, especially in the bale. They are willing and desirous, if rags can be shown to be infected or to have been gathered in infected districts, that these rags shall be destroyed. But they protest that it is a gross outrage on

them and on the public that their property coming from uninfected districts, in ships bearing clean bills of health, shall be subjected to a patent disinfecting process. They demand, and they think they have a right to demand, that if disinfection be required, it may be done by some other than a patented or secret process. Nominally a choice is given between two processes; in reality only one can be applied, and that one belonging to what, for want of a better term, I shall call the Quarantine Ring. This is being done now and here in the name of 'sanitarian' vigilance and 'humanitarian' zeal, and the medical profession are asked to approve it. I would respectfully ask them to examine carefully and consider candidly these facts before lending their powerful support to such a scheme."

Dr. John Dudgeon and His Work in China.—The people of China—an aggregate of over 250,000,000 of the human family—are under the deepest obligations to Dr. Dudgeon. This distinguished member of our profession, says *The Lancet*, has lived among them twenty years and more, with his head-quarters at the capital. He has there a hospital and a dispensary, which have been fruitful of incalculable good to thousands. He has also set up in the Foreign College, with the sanction of the government, the nucleus of a medical school for the behoof of those of the young Chinese who propose making physic the business of their lives. He is himself the Professor of Anatomy; and he has a colleague who teaches chemistry—a science which, along with anatomy, is perhaps the best introduction the Chinese can have to the study, not of medicine only, but of the other departments of natural science also. Very valuable has been his work as a professor. Utterly ignorant of anatomy as Chinese medical men are, Dr. Dudgeon is on the eve of doing the rising generation of them a signal service. He has just translated into Chinese two English works of great value—Holden's "Osteology" and Gray's "Anatomy"—both containing all the wood and other engravings to be met with in the originals. By means of these, apart even from the actual dissection of the human body, the Chinese students cannot fail, thus aided with figures and with the living voice of the professor, to acquire a fair knowledge of the make and constitution of the human frame. The dissection of it, if not forbidden by law, is at least a thing abhorrent to the people. Ere long, it is to be hoped that people and students alike may be able to say, in a sense of their own, what M. Snagarelle so confidently affirmed in reply to M. Géronte as to the relative position of the liver and the heart, "Nous avons changé tout cela." Nor is this all that Dr. Dudgeon has done for them. He is at present, we understand, engaged in translating for them, with all its engravings, Dr. Kirkes' "Handbook of Physiology." Dr. Dudgeon is surely deserving of the highest honor in thus largely putting before the Chinese, in an orderly and systematic form, truths of the greatest value to them as a nation.

The Cost of Managing the Hospitals of New York.—At a meeting of the Hospital Saturday and Sunday Association, December 21st, Mr. Stone submitted a statement showing the work and resources of each of the hospitals connected with the association for the year ending September 30th. The total expenses of the twenty-one hospitals were $601,801.44. There was an income from invested funds of $127,099.20, and from city, county, and State appropriations of $29,635.93. The amount received from contributions other than gifts or bequests to the permanent fund was $201,492.58; through the Hospital Saturday and Sunday collection, $29,917.10; from paying patients, $136,403.68—making total contributions applicable to hospital expenses, $524,016.33. The number of patients treated in the hospitals for the year was 11,969, of whom 9,332 were free patients, at a cost of $476,000. In addition, medical aid was extended to 109,741 cases through the outdoor and dispensary departments.

Investigating Contagious Ophthalmia in the Schools.—Dr. Derby, in a communication to the Board of Health, last week, said that contagious ophthalmia among children in public institutions had increased to such an extent that the Academy of Medicine had taken the matter up, and the Committee on Ophthalmia had arranged to thoroughly investigate the disease. About twenty-five prominent physicians had been selected to visit the institutions, and the Board was requested to appoint them as sanitary inspectors without pay. Colonel Prentice, counsel to the Board, sent in an opinion on the request yesterday. It is to the effect that the appointment of special sanitary inspectors, without pay, would not be proper, and he suggested that regular sanitary inspectors be detailed to accompany the physicians selected by the committee, so that the investigation and its results can be reported to the Board. A resolution directing the Sanitary Superintendent to detail two inspectors to accompany the physicians was adopted.

At a Meeting of the Lackawanna County Medical Society, December 8th, a telegram was received from Dr. J. V. Shoemaker, of Philadelphia, asking the society to rescind their resolution of last month condemning the action of the American Medical Association's new committee in excluding eminent physicians from the Congress. A motion to reconsider the resolution of last month was offered, and, after an animated discussion, was defeated.

"New Yorker Medizinische Presse."—A new monthly medical journal, under the above title, has just appeared in this city, edited by Dr. Geo. W. Rachel. It aims to be the organ of the German-American physicians of the country. It is intended to furnish an opportunity for the many German physicians ere who do not care to trust themselves in English to publish the results of their work and observation. The first issue contains a number of excellent original articles.

Medico-Chirurgical Society of German Physicians.—At the last meeting of the Medico-Chirurgical Society of German Physicians, the officers for the following year were elected as follows: President, Dr. C. Heitzmann; Vice-President, Dr. L. Weber; Recording Secretary, Dr. Willy Mayer; Corresponding Secretary, Dr. H. J. Garrigues; Treasurer, Dr. A. Throg.

Dr. Harman Leslie Snow, of Albany, N. Y., died on December 19th, after a long illness. He was President of the Common Council, and partner of Dr. Vanderveer. He was forty-nine years of age.

The Medico-Chirurgical College of Philadelphia announces that it will not indorse any diploma of a person coming from other States and intending to register and practise in Pennsylvania, without the holder first passes a satisfactory examination. Fee, $30.

Several Cases of Small-pox that had been concealed have been hunted up by the Board of Health during the past week. New York physicians are not making a specialty of reporting cases of this kind just now, the penalty for such work being from $500 to $10,000.

Long Island College Hospital, Brooklyn.—Professor A. P. Grinnell, M.D., of the University of Vermont, will give the course of lectures on the Practice of Medicine at the Long Island College Hospital the ensuing year.

The American Supply of Doctors.—It is estimated that there are now in the United States 120,000 practitioners of medicine, including non-graduates.

Pasteur's Inoculations against Rabies.—The four Newark children who were sent to Paris to receive treatment by Pasteur have arrived, and the inoculations began on December 21st. A cablegram to *The Times* announces that Pasteur has now under treatment 20 cases, and that he has treated 114 since the beginning of his experiments.

Protesting against the Laicization of the Paris Hospitals.—The hospital physicians and surgeons of Paris, to the number of 106, have signed a petition, addressed to the Minister of the Interior, praying that the *religieuses* in the hospitals to which they are attached may be retained.

The Library of the College of Physicians of Philadelphia. — At the December meeting of the College the standing committees presented their annual reports. The Library Committee reported that the library now contains 33,686 volumes and 1,393 unbound pamphlets, an increase in the year of 2,592, as compared with 1,261 in 1884, and 869 in 1883.

The Death of Henri Bouley, Professor of Comparative Pathology, is announced. Professor Bouley has long occupied the highest rank among students of comparative pathology. He was a member of the Académie de Médicine, and of the Académie des Sciences, and was Inspector-General of Veterinary Schools. He was an ardent supporter of the views of Pasteur. Among his principal works were a treatise upon rabies and a treatise upon the anatomy of the horse's foot.

No more Medical Women.—It is reported that the New York Post-Graduate Medical School will not receive medical women as matriculants after the present session.

"The Christian Nation" is a religious journal which deserves hearty praise or two reasons—it refuses quack advertisements, and it denounces the "faith-cure" humbugs.

Death of Dr. John S. Heard.—Dr. John S. Heard, aged 70 years, died at Newburg, N. Y., on December 17th. Deceased was born in New York City. He graduated from Columbia College in 1834, and from the New York College of Physicians and Surgeons three years later. On graduating from the latter institution he became one of the two resident surgeons of the New York Hospital. In 1840 he began the general practice of medicine in New York City, continuing for twenty years. He gave up his practice in 1860 and went to Newburg, where he has since resided.

Priority in Inoculations against Rabies.—The last thing thought of would be that a claim of priority would be put in against Pasteur's preventive inoculations against hydrophobia. We learn, however, from *Le Progress Medicale*, that in a medical journal called *Klinische Anweisungen*, appearing in Leipsic in 1849, under the title of "Rabies and Poisoning," an article is published discussing a method of preventing rabies by vaccination. The doctor employing this measure called himself Constantin Hering, and lived in Philadelphia.

The Stomach and the Soul.—Twelve thousand people are daily under the charge of the Commissioners of Charities and Correction of New York City in the various hospitals and institutions over which that board has supervision. It costs the city $1,500,000 a year to care for their stomachs, while only $30,000 is spent on their souls, according to the statement of the New York Protestant Episcopal City Mission.

Death of Dr. Isaac G. Collins.—Dr. Isaac G. Collins, of Sing Sing, died on September 17th, aged 53 years. He was born in Greenville, N. Y., and was a graduate of Union College and the Albany Medical College in 1858. He began practice in Sing Sing in 1864.

DAMAGES FOR REPORTING A CASE OF CONTAGIOUS DISEASE—AN APPEAL TO THE PROFESSION.

Brown *vs.* Purdy.

The facts of the above case are briefly as follows: In November, 1879, Dr. A. E. M. Purdy was called to see Miss Angelina Brown. On his arrival he diagnosticated small-pox. He saw her later in the day with Dr. A. S. Purdy, who likewise diagnosticated small-pox. Still later he saw her again with Sanitary Inspector Dr. C. E. Lockwood, whom he had notified of the case. Dr. Lockwood's diagnosis was small-pox. The patient went or was sent to the small-pox hospital. On her arrival the house-physician, Dr. Bowen, made a diagnosis of small-pox, and so reported to the Board of Health. He subsequently revised this diagnosis and certified that Miss Brown was only suffering from eczema, and told her that she need not remain in the hospital. She voluntarily remained there, however, for some days.

After leaving the hospital she brought suit against the Drs. Purdy, claiming damages to the extent of $10,000. She asserted that the diagnosis made by Drs. A. E. M. Purdy, A. S. Purdy, and C. E. Lockwood was incorrect, and that she had been damaged to the above-named amount by being sent to the small-pox hospital, and that she was sent there through the agency of the Drs. Purdy.

On the trial of the cause in November, 1885, in the Superior Court, before Judge Ingraham, the counsel for the defendants moved to dismiss the complaint, on the ground that the defendants had not sent the plaintiff to the small-pox hospital, but that the sending of Miss Brown to the hospital was the act of the Board of Health, for which the defendants were not responsible.

His Honor denied the motion, and ordered that the trial proceed before the jury.

The plaintiff on the stand gave a lengthy history of her experiences, and declared that she was not suffering from the small-pox in November, 1879, but from the effects of a local irritant that she had applied to the skin.

The defendants testified minutely as to the symptoms and eruptive appearances presented at the time of their examination, and declared that they were unmistakably indicative of small pox.

Dr. Lockwood testified to the same effect, and that his opinion was formed independently of the Drs. Purdy, and *that Miss Brown was sent to the hospital in conformity with the rules and regulations of the Board of Health.*

Drs. Austin Flint, E. L. Keyes, and Geo. H. Fox testified that, from the recital of symptoms and character of the eruption as detailed by witnesses, Miss Brown was undoubtedly suffering from small-pox at the time referred to. Other physicians were in court prepared to testify to the same effect.

At the close of the testimony the counsel for the defence again moved that the case be dismissed, on substantially the same grounds as before, to wit: that it was the Board of Health and not the Drs. Purdy that caused the transfer of the plaintiff to the hospital.

His Honor again denied the motion, and in his charge to the jury said in effect, that *the defendants had set in motion the machinery* that led to the plaintiff being sent to the hospital.

The jury brought in a verdict of $500 against the defendants.

The features of the case that are important to the medical profession of this State do not hinge on the correctness or otherwise of the diagnosis.

The essential point is whether a physician who complies with the law, requiring him to report cases of suspected small-pox, thereby becomes liable for any damage arising or claimed to have arisen through the subsequent acts of the Board of Health.

The decision of Judge Ingraham in sending the case to the jury would imply that the physician may thus become liable.

This decision, in accordance with judicial custom, will be considered law until reversed by a higher court.

The case of Brown *vs.* Purdy having been brought to the notice of the Medical Society of the County of New York, that body referred the matter to its *Comitia Minora* with power. The *Comitia*, believing that it would be expedient to appeal from Judge Ingraham's decision, provided sufficient funds could be raised, appointed a special committee, consisting of members of the Society, for the purpose of raising said funds.

This committee appointed a sub-committee to prepare a brief statement of the facts of the case, and the foregoing is their report.

(Signed) H. G. Piffard,
Daniel Lewis,
P. A. Morrow,
Frederick R. S. Drake,
A. H. Smith,
Sub-Committee.

In the light of the facts as above stated, the special committee earnestly urge the members of the Medical Society of the County of New York, to contribute to the fund now being raised for the purpose of carrying the case to the higher courts. To this fund Dr. A. E. M. Purdy has subscribed one thousand dollars, and Dr. C. R. Agnew five hundred dollars. Other subscriptions, of one hundred dollars and under, have been received. Additional funds are still needed and may be sent, by check or otherwise, to Dr. O. B. Douglas, 123 East 36th Street.

Any part of the fund not required will be returned pro rata when the suit is decided.

By order of the Special Committee,
Daniel Lewis, *Chairman.*
F. R. S. Drake, *Secretary.*

Obituary.

PROFESSOR JOHN C. DRAPER, M.D., LL.D.,

NEW YORK.

The death of Professor John C. Draper, of this city, occurred on the 20th inst., from pneumonia, after an illness of four days. He was the eldest son of Professor John W. Draper, and was born on March 31, 1835, in Virginia. He entered the University of the City of New York in 1852, and left it in 1854, in his junior year. He then entered the medical department of the University, from which he was graduated in 1857. For a year prior to this he had held the position of House Physician and Surgeon of Bellevue Hospital. In July, 1857, he went to Europe for the double purpose of advancing his studies and regaining the health which he had lost by a too persistent application to them. Upon his return, in December, 1858, he was appointed Analytical Chemist in the University of the City of New York. This position he retained for thirteen years. In 1860 he assumed the Professorship of Chemistry in the Cooper Institute, but relinquished it in three years. For six months, in 1862, Professor Draper served as Surgeon in the United States Volunteers, and was on General Wood's staff at Harper's Ferry when that place was surrendered. In 1863 he became a member of the New York Academy of Medicine, and became a member of the Council of that institution in 1870. It was also in 1863 that Professor Draper was elected to the Chair of Natural History of the College of the City of New York. This position he retained up to the time of his death. In 1866 he became Professor of Chemistry in the medical department of the University of the City of New York. In the academical, as well as the medical, department of the University, he was one of the most popular lecturers.

Professor Draper was widely and favorably known as an author. On his recent trip to England he was made the recipient of special hospitality by distinguished literary and scientific bodies. The results of his researches in chemistry have been made widely known by articles published from time to time for a number of years and in book form. The Professor's first effort in book form was a text-book on anatomy, physiology, and hygiene. It was published in 1865. Fourteen semi-scientific articles from his pen appeared in the *Galaxy* from 1868 to 1871, inclusive. These treated of such subjects as diet, dress, and ventilation. They were of general interest, and in certain parts of the country one of them, "Tobaccophagoi and Tobaccophagism," an able argument against the use of tobacco, drew down upon the author a storm of abuse and some threats. He received one letter from a Texan who promised to shoot him if he wrote any more on the same subject. Professor Draper edited "Scribner's Year Book of Nature and Science" for 1872, and the same periodical for the following year, when it appeared as "Draper's Year Book of Nature and Science." He also edited the department under this head in *Scribner's Monthly* up to 1876. In addition to a number of scientific papers of much importance, written subsequent to 1876, he completed, in 1882, and had published by William Wood & Co., "A Practical Laboratory Course in Chemistry." This work has since held an important place among text-books. His last work, an advanced text-book on medical physics, was published a short time before his death by Lea Brothers & Co., of Philadelphia. It contains nearly four hundred illustrations, and the work proved of such absorbing interest to the author that the attention he gave it probably hastened his death.

The degree of LL.D. was conferred upon Professor Draper by Trinity College, Hartford, in 1873. This was only one of many honors conferred upon him by learned societies. He was married in November, 1864, and leaves a widow, but no children.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 25, 1885.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

DR. H. J. BOLDT presented, in behalf of a candidate, a specimen of *Bilateral cysts of the capsules of the kidneys.* The specimen was referred to Dr. Prudden for examination and report.

Dr. Boldt also presented the

BRAIN AND MEDULLA OF A CAT.

Some time ago he encountered serious symptoms from the use of cocaine, and, therefore, determined to experiment upon animals with the drug. In the presence of Drs. Spitzka, Waldstein, and Brill, he injected eleven minims of a thirty-three and a third per cent. solution of cocaine into a cat weighing seven and a half pounds. Death took place twelve minutes after the injection was administered. The first effect noticed was a sort of leaping gait, with dragging of the hind extremities, and soon convulsions took place, probably forty in number. After each convulsion there was a period of quiescence, during which the legs of the animal straightened, the head turned up, the neck curved backward, and immediately afterward a severe convulsion took place. The respiration simulated the Cheyne-Stokes. After death the temperature in the rectum was 104° F.

An autopsy was made half an hour after the animal ceased to breathe. A small quantity of dark-colored blood oozed from the dura mater, and the vessels of the pia mater of both brain and cord were intensely congested. There was an extravasation of blood in the fourth ventricle, and also a small extravasation in the anterior part of the medulla. There were minute extravasations all through the brain.

The lungs were entirely collapsed, empty of blood, and the right ventricle of the heart was overdistended; the left empty. Death seemed to have taken place through paralysis of the respiratory centre. The gray substance of the cord was overfilled with blood, and resembled, as Dr. Spitzka remarked, a bloody sponge.

DR. PUTNAM-JACOBI remarked that the phenomena described by Dr. Boldt implied rather contraction of blood-vessels from vaso-motor irritation analogous to the contraction observed after a local application of cocaine, and that death was due not so much to direct effect upon the respiratory centre as to contraction of the blood-vessels in the lungs and secondary obstruction to the circulation in the right side of the heart.

THE PRESIDENT remarked that all the capillaries throughout the body being affected, the heart was paralyzed, and first the right ventricle, because it was the weaker.

DR. BOLDT said that might be the case, but clinical experience had shown that the most important trouble after the use of cocaine was primarily encountered in the respiration.

THE PRESIDENT remarked that, according to his experience, respiratory and cardiac shock was more likely to occur from invasion of the surface in the neighborhood of the fifth nerve than in any other locality.

DR. PRUDDEN asked what the appearances were which led to the statement that the lungs were anæmic.

DR. BOLDT replied that they were entirely devoid of air, and were of a pale color.

DR. PRUDDEN remarked that the lungs of a cat are very white normally, and fall back from the chest when the sternum is removed as compared with the human lung.

THE PRESIDENT directed attention to the danger of using chloroform or ether after the use of cocaine, and cited a case in the practice of a distinguished surgeon in which the life of the patient was nearly lost by administering chloroform after cocaine had been used unsuccessfully. The heart ceased to beat and breathing stopped, but the patient was resuscitated after about five minutes of artificial respiration.

The same surgeon had also told him of a case in which he knew the same result to follow the administration of ether after the use of cocaine. He believed that it would be well for the Society to express itself in unmistakable terms concerning the danger of the use of either chloroform or ether after the use of cocaine.

DR. WESLEY M. CARPENTER remarked that the Society had already expressed, in most positive terms, its opinion against the use of chloroform as an anæsthetic.

ABSTRACT OF THE CASE OF PROFESSOR PANUM.

DR. D. BRYSON DELAVAN presented a photograph of the late Professor P. L. Panum, President of the last International Medical Congress, together with a history of his last illness and death, translated by Dr. Holger Mygind, from the report made by the attending physician, Professor Frier, to the Medical Society of Copenhagen. Professor Panum, aged sixty-four and a half years, had always enjoyed good health. Ten years before death chronic bronchitis, with frequent acute exacerbations, developed, followed by emphysema which, two or three years later, became well marked. His symptoms were confined mainly to cough and slight dyspnœa, the latter particularly apparent upon going upstairs. It never reached any important degree, however, until the last weeks of his life, when it became more severe and was attended with oppression. The attacks were usually short. Physical explorations of the chest revealed no disease of the heart or of the large vessels.

On the first of May, while returning home in a high wind, Professor Panum experienced some difficulty in walking, and was unable to keep up with his companions, stopping several times evidently to rest and regain his breath. Soon after returning home he felt severe pain in the region of the heart, and a sudden feeling as of something bursting in the left side of the chest. The pain increased and the patient became uneasy and alarmed. When seen by Professor Frier, at 10 P.M., he was pale, somewhat collapsed; the skin cool and not perspiring; the pulse slight, frequent, and irregular. He talked freely and his respiration was not particularly accelerated. He moved about the room easily, undressed quickly, and went to bed. Here he continued to complain of pain, which now included the sternal region, and radiated out into the left arm and to the fingers. He was very restless and with difficulty repressed exclamations of pain. Attempts to give warm and stimulating drinks failed, as they only produced nausea. His mind was perfectly clear. Hot applications and counter-irritants applied to the chest gave no relief, nor did a hypodermic injection of morphine. About midnight the pain began to decrease, and after another hypodermic he fell into a light, uneasy sleep. The pain did not return until about 8 A.M. the next morning, up to which time he felt so well that he was with difficulty persuaded to remain in bed and give up his morning lecture; he gave directions, however, as to his business letters. His own diagnosis of his case was functional disorder of the vagus and sympathetic nerves. Half an hour after his son had left him, his pulse being strong and his general appearance decidedly improved, and a few moments after he had spoken jokingly to those around him, he suddenly groaned, fell back cyanotic and unconscious, and, a few minutes later, died.

From the superficial examination made the night before, no increased dulness of the heart had been discovered, but tumultuous action, with long, strong murmurs which prevented the two heart-sounds from being heard or distinguished. Professor Frier's diagnosis was angina pectoris. The real cause of death was discovered post-mortem. Autopsy, May 3, 1885, twenty-nine hours

after death, made by Dr. Dahl. Rigor mortis well marked, death suggillations all over. The panniculus adiposus well developed on chest and abdomen. The upper lobes of both lungs and the right middle lobe emphysematous and œdematous. No fluid in the pleural cavities. Mucous membrane of bronchial tubes somewhat injected and covered with cohesive white mucus. The pericardial sac filled with a little more than a pint of dark fluid and clotted blood. Blood of a similar appearance was seen to flow out of a fissure of the anterior left ventricular wall. The fissure was five centimetres long, and was parallel with and close to the septum. Its edges were lacerated. A similar but smaller fissure, one centimetre and a half in length, was seen along the first one, and united to it by a cross fissure. Both extended through the subpericardial fatty tissue, which was infiltrated with blood and reached the muscular substance; this was perforated by several small fissures and holes, none of which were more than large enough to admit a probe. In the lower part of the fissure the probe entered a small cavity between the muscular and fatty layers which was filled with blood. Heart flabby, with much subpericardial fat, especially at apex, where it was more than one centimetre thick, while at the seat of the fissure it was exactly one centimetre. In a few places the pericardium was thickened and white. Length of heart thirteen centimetres, breadth the same. The apex was formed by both ventricles, and a little rounded. Aortic valves normal. Foramen ovale open. The tricuspid orifice admitted three fingers, the mitral four. The tricuspid and pulmonary valves were healthy. On the anterior mitral flap there was a large, white, thickened patch. The right ventricular wall was two millimetres thick, the muscular tissue being of a deep, dull, grayish-brown color. Toward the septum there was a limited yellow area, extending somewhat in depth. The cavity was enlarged. The left ventricular cavity was much enlarged, the wall at its thickest part being 8 mm., at the apex 2–3 mm. The trabeculæ were flattened and not much developed. Muscular papillæ of normal thickness, the muscular tissue flabby, much softened, and of same color as that of right side. At several places yellow spots were seen through the endocardium. Toward the septum, at a point corresponding to external fissure, was a rectilinear fissure four centimetres long. It did not quite correspond to the external one, crossing it at an acute angle. The edges of this fissure were flattened. At the bottom of it were several small holes, corresponding to those described in the external fissure. The surrounding tissue much softened, and infiltrated with dark blood. A fresh cut across the fissure and through the muscular layer showed this to be very thin, about two mm. close to the edge, and five mm. farther away. Aortic valves somewhat thickened. In the tunica intima were many white fibroid patches, and similar ones were found in both coronary arteries. In the vertical branches of the left, just after its separation from the horizontal branch, was found a constriction which barely admitted the passage of a fine probe. Upon opening the artery, here was found a soft, whitish-yellow plug, which covered a softened atheromatous cavity formed in the thickened and partly calcareous intima, which was perforated in several places by small holes. From here down to the rupture the artery seemed healthy. A little below the plug a small branch went off; it could be followed to the spot of fatty degeneration in the right ventricle.

Microscopical examination of the muscular tissue showed the fibres around the fissure to be atrophied and very fatty. There were no transverse striæ visible and no increase of the interstitial fibrous tissue. Nuclei normal; many fibres broken by extravasation of blood. Specimens taken from other parts of the heart showed the transverse striæ were well marked, but everywhere there was more or less fatty degeneration. Other organs not examined. The plug which caused the fatty degeneration had probably developed during the last few weeks before death, causing the dyspnœa and oppression. The resulting rupture was probably observed by Professor Panum himself; but it seemed to have slowly penetrated the wall from within outward, not causing at first effusion into the pericardial sac, but only irregularity of the heart's action, pain, and nausea.

Dr. Van Santvoord presented a specimen of

CARCINOMA OF THE UTERUS,

probably primary of the cervix, and later involving the body of the organ. The clinical history had no special interest except the fact that the woman was confined and delivered of a living child within three days of her death.

At the autopsy the brain was not examined. The lungs exhibited a slight amount of hypostatic congestion. The heart was apparently somewhat fatty. The liver was pale on the surface, the intestines and omentum showed irregular patches of pigment, and the retro-peritoneal glands were also pigmented. In the broad ligament there were a number of irregular patches of pigment. The body of the uterus was about twice the normal size, closely adherent to the lower third of the rectum and to the bladder in front. The kidneys were exceedingly anæmic, their pelves considerably dilated, and one pelvis contained considerable clear urine. The ureters were dilated.

The uterus was firmly fixed; the cervix had been eaten entirely away by the malignant process; there was an ulceration into the urethra just as it joins the bladder, and the ureters were somewhat obstructed by thick, dense, fibrous tissue. The vagina was the seat of cancerous infiltration, and the endometrium also exhibited some thickening, due to the same process.

Dr. Van Santvoord also presented a specimen of

TUBERCULOSIS OF THE PHARYNX

which occurred in an infant, about two years of age, admitted to the Randall's Island Hospital four months before its death, in a cachectic condition, accompanying a large mass of enlarged glands under the angle of the jaw upon either side. The cachexia increased, and two and a half months before death slight cough was noticed, although nothing was discovered in the lungs except a few râles. About four days before death the house-physician thought the child had some difficulty in swallowing, and the larynx was observed to be covered with a thin grayish coating; the temperature 102.5° F. in the evening. Four days afterward the patient died of exhaustion.

At the autopsy the enlargements upon each side of the neck were found to be caseous lymphatic glands. The pharynx presented a roughened and somewhat worm-eaten appearance, with lenticular ulcers extending to some depth into the mucous membrane. The uvula was thickened and covered with granular elevations. The mucous membrane of the nasal cavities presented the same roughened appearance, and also the vault of the pharynx, from which it extended upon the nasal septum about one-fourth of an inch, and the convex surface of the inferior turbinated bodies also was in somewhat the same condition. The larynx upon the posterior surface had two small ulcers. Miliary tubercles were found in the lungs and also upon the pleural surfaces. In the middle lobe of the right lung was a single soft caseous nodule, with a number of areas of broncho-pneumonia. The spleen was filled with miliary tubercles. A number of tubercles were also noticed in the liver, and also in the kidney. In the intestines there were several tubercular ulcers. The retro-peritoneal and mesenteric glands formed a large mass which had undergone cheesy degeneration and was breaking down. The case was, therefore, one of the somewhat rare affection known as tubercular ulceration of the pharynx. Dr. Mackenzie, of London, has reported a number of cases, and says that they are more frequent than is generally supposed, and

that they are doubtless frequently mistaken for syphilitic disease.

Dr. Van Santvoord also presented the stomach and large intestine removed from the bodies of animals that had died of

HOG CHOLERA.

The stomach showed considerable gastritis, and at one point there was a necrotic spot, or so-called ulcer, sometimes observed in the stomach, but almost entirely in the large intestine, where it formed the characteristic lesion. The ulcer showed a dark, dirty sloughing centre, with yellow elevated edges, and this characteristic process extends to a variable depth, sometimes reaching the peritoneum.

The large intestine showed a swollen ileo-cæcal valve, chiefly on the side toward the colon, with irregular ulcers, and from about ten inches above the cæcum the gut was intensely hyperæmic as far as the descending colon, and the entire mucous membrane was sloughing, at least in the superficial portion. In the descending colon were seen enlarged solitary follicles with depressed, slightly ulcerated centres, and these also showed distinctly upon the peritoneal surface of the gut, as semi-translucent, pearl-like spots.

The other lesions found in the cases which he had examined were as follows: in the brain and cord he had found lesions in two cases; in two cases there was broncho-pneumonia, and in all a certain amount of œdema of the lungs with some mucus in the bronchi. In one case there were ecchymoses under the pericardium and endocardium. In one case the liver showed perihepatitis, and in another it showed a slight amount of flocculent lymph. In all of the cases there was enlargement of the mesenteric and retro-peritoneal glands, and in one of these the ecchymoses which occur so frequently. The spleen was normal in all the four animals examined. The kidneys showed no lesion except one in which there were a few small nodules, and also in the liver of the same animal there were a few nodules of the same character; but Dr. Van Santvoord was inclined to think that they had nothing to do with the disease of which the animal died.

Dr. Prudden remarked that although much has been done in the way of investigating the swine plague and the relation of bacteria to it, the matter does not yet appear to have been cleared up. While Pasteur asserted that his rouget was caused by a figure-of-8 coccus resembling that of chicken cholera, but not identical physiologically with it, Schütz found in the attenuated virus furnished by Pasteur himself, as well as in hogs affected with the disease in Baden, a fine bacillus apparently identical with the bacillus by septicæmia of mice of Koch. Klein's bacillus of swine plague is apparently not identical with that of mice septicæmia. The micrococcus of Salmon, recently redescribed in the report of the Bureau of Animal Industry for 1884, and of which he (Dr. Prudden) has in his laboratory pure cultures, received through the courtesy of Dr. Billings, of Washington, certainly could not be mistaken for a bacillus, nor does it resemble very closely the figure-of-8 coccus of chicken cholera. Löffler's experiments would suggest that this polyonomous disease may, after all, not be in all cases the same thing nor due to the same causes.

Dr. Delavan remarked that tuberculosis of the pharynx was unusual in adults, and its existence had been denied. There were cases sufficient, however, on record to make its existence undoubted. It was not by any means a common affection. He had seen three cases. The history of Dr. Van Santvoord's case was decidedly different from that of the same affection in the adult, because in adults the painful nature of the disease was very pronounced. He thought he had not seen a more painful case than one under his care of tuberculosis of the pharynx. The ulcers are particularly sensitive, and give rise to the most distressing dysphagia. The extreme painfulness had been regarded as one of the diagnostic points between tuberculosis of the pharynx and syphilis, as the affection often resembled syphilitic ulcers sufficiently close to mislead practitioners, and, besides, being so very rare, one was very liable not to think of the local affection being tubercular.

The Society then went into executive session.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 17, 1885.

Abraham Jacobi, M.D., President, in the Chair.

VAGINAL AND VULVAR ENTEROCELE.

Dr. T. Gaillard Thomas read a paper on the above subject, in which he defined *five* varieties of herniæ that may show themselves in the vagina and vulva: 1, cystocele, or hernia of the bladder; 2, rectocele; 3, vaginal enterocele; 4, pudendal enterocele; 5, perineal hernia, or descent of small intestine by protrusion through the perineum.

The author of the paper passed hernia of the bladder and of the anterior wall of the rectum, and confined his remarks to descent of the intestines through the pelvic roof, protrusion through the labia majora and vagina, and through the perineum.

Attention was first directed to the scarcity of the literature of the subject, only very slight mention, or none at all, being made of it in works written by obstetricians and gynecologists. It was first mentioned in 1786. Sir Astley Cooper treated fully of it in 1804. The best account of it was published in the French Dictionary of Medicine in 1846.

Vaginal enterocele is descent of intestines into the pelvic cavity, either in front of, or posterior to, the broad ligament of one side. Usually intestines alone descend in this hernial protrusion; sometimes omentum accompanies them; possibly the sac may contain omentum alone. Usually small intestine makes up the contents of the hernia. It develops in the following manner: A loop of intestine gradually pushes downward the peritoneum, which forms the pouch of Douglas, a tumor forms in the vaginal canal, and may end by hanging outside of the body. Such a tumor has for its coverings: first, inverted vaginal wall; second, peritoneum; and for its contents intestine.

Unquestionably the greatest danger from this form of hernia arises from possibility of error in diagnosis, either in the parturient or non-parturient woman.

Dr. Thomas then gave the histories of two striking cases of error in diagnosis. The first was one in which a portion of intestine, and also of the omentum, was removed with what had been diagnosticated as a polypus. In the second a supposed abscess was opened, intestine protruded, and the patient died of gangrene.

The most frequent cause of these varieties of hernia is parturition. Nevertheless, some of the most striking cases have occurred in non-parturient women.

Vaginal hernia is often of but little account, and gives rise to only slight inconvenience, so long as it remains within the vagina.

The prominent symptoms are difficulty in locomotion, pelvic tenesmus, colicky pains, dragging sensations, etc. Obstructed labor is liable to result. A tumor of greater or less size is found, soft and yielding, which decreases in size by pressure, increases by coughing, gives a sense of gurgling, resonance on percussion, and is usually reducible by taxis, with the patient in the knee-chest position.

The conditions from which it is to be differentiated are prolapse of the vagina, uterus, bladder, and rectum; vaginal cyst; simple par-ovarian cyst and fibrous tumor pressing low down in the pelvis; cold abscess of the pelvis, and marked cases of tubal dropsy.

Most cases present striking features, and with proper care mistakes in diagnosis will not be made. It may develop suddenly, more commonly in a gradual manner.

Dr. Thomas then reported a case in which a consultant was unwilling to give an opinion in a case of suspected extra-uterine pregnancy without introducing the entire hand into the vagina, which he did with the patient anæsthetized, and when he withdrew his hand a loop of intestine followed it, having escaped through a rent made in the vagina. Dr. Thomas sutured the laceration, and the patient barely escaped with her life, after having had a severe attack of peritonitis.

Pudendal enterocele is recognized by the presence of a small-sized elastic tumor, about the middle of the labia majora of one side. The manner of its formation was then described.

The conditions with which it is liable to be confounded are, cyst or abscess of the vulvo-vaginal glands, cyst of the labia minor or major, abscess of the labium major, fatty or fibrous tumor of the labia, and tumors descending from the pelvic cavity into the labium of one side.

Erroneous diagnosis will probably lead to a fatal issue. The symptoms almost pathognomonic are: 1, Airy feeling upon palpation; 2, gurgling on replacement; 3, diminished tension in dorsal decubitus; 4, diminution in bulk on taxis; 5, resonance on percussion; 6, succussion upon coughing; 7, abdominal pains of a colicky character.

Perineal hernia may effect both male and female. In the latter it consists of a descent of intestines between the vagina and rectum, the advance being made posterior to the broad ligament. In the female it may be felt through the rectum and the vagina. All these varieties of hernia are amenable to taxis, the manipulation being aided materially by the knee-chest position. Strangulation may occur. Dr. Thomas then reported a case of extreme vulvar hernia, occurring in a multipara, thirty-nine years of age, who about six years ago first noticed a small lump in the vulva on the right side, and began to suffer from difficulty in locomotion and in micturition, dragging pains in the back, and general malaise. The tumor gradually increased in size, and finally extended downward to the middle of the thigh. The tumor could be made to disappear by taxis, with very slight gurgling, but resonance on percussion did not appear distinctly. It was impossible to retain the hernia by mechanical apparatus.

For it Dr. Thomas proposed to perform the following operation, which was endorsed by his colleagues, Drs. Emmet and Bozeman. First, laparotomy, causing an assistant to keep the hernial sac well within the pelvis by means of one hand within the vagina, then to pull all the contents out of the sac, seize the sac at its most dependent part, drag it up and fasten it into the abdominal wound with sutures, sustaining the heavy sac by two knitting-needles passing through and lying flat across the abdomen.

The operation was complicated by encountering a tumor of softened œdomatous fibrous tissue, diagnosticated by Dr. H. C. Coe, pathologist to the Woman's Hospital, as a soft *fibroid tumor of the pelvic connective-tissue*, which was removed. The patient did well, and now, five weeks after the operation, there is no sign of returning hernia.

With reference to these varieties of hernia little could be said concerning treatment, as we were poor in methods of affording decided relief, and had no means of cure. Should he meet with other cases, however, Dr. Thomas would be inclined, if they were of sufficient gravity, to perform laparotomy and drag the sac up, as was done in the case reported.

Dr. Castle, from the Committee on Revision of the Constitution and By-laws, read the report, after which the Academy adjourned.

The Mortality from Hydrophobia.—In England and Wales during the years 1870 to 1883, has averaged from 31 to 82 in a population of about 20,000,000. The total number of deaths in thirteen years, was 635.

Correspondence.

SOME CURIOUS FACTS CONCERNING "THE JUMPERS."

To the Editor of The Medical Record.

Sir: During a somewhat protracted term of service as United States Sanitary Inspector on the northern frontier of Maine, between Canada and the United States, I have been much interested as well as amused in watching a certain class of individuals found among the hordes of French-Canadians who pass annually from all parts of Canada into the States, particularly into Maine and other lumbering districts. These people to whom I refer go by the name of "jumpers."

They attracted my attention as presenting some points of interest bearing upon the nervous system, showing to what a hyper-sensitive condition it may be brought by certain influences early begun and long continued.

I had from time to time heard lumbermen and others whose avocations lead them to spend much time among the French camps speak of these "jumpers," but had given no credence to the, as I thought, absurd stories they related in regard to them, until one day, while attending to my duties in the waiting-room of my fumigating station, I incidentally let fall the window near my desk, by turning the button suddenly, thus letting the frame fall a short distance, making a quick, sharp noise, when three out of seven French-Canadians who were sitting near, awaiting their certificates of inspection, leaped into the air as if they had been shot, at the same time uttering a yell which would have done credit to a North American Indian. From that time I was on the watch for these strange characters, and, when possible, made inquiries of them through my interpreter in regard to the cause of their condition. Before speaking of this, perhaps it will be well to enumerate some of the manifestations which give them the characteristic name of "jumpers." One or two instances will be sufficient. Recently one of them, a French-Canadian of small stature, came out from an adjacent camp to the post-office. Just as he was about to ask the postmaster for his mail, he being a total stranger to the official, a man of sixty-five years of age, some one knowing the fellow to be a "jumper," mischievously cried out: "Grab him by the throat!" The fellow sprung like a cat and grasped the old man by the throat, and held on until removed, the irate postmaster pouring forth torrents of invectives on the poor fellow, who really was perfectly guiltless.

Another unfortunate wood-chopper had just come into camp from two days' work, and was standing near the large camp-heater, in which was a very hot fire, when some one cried: "Grab the furnace!" No sooner were the words said than the poor fellow obeyed the order, and as a result left a scorched pattern of each hand on the nearly red-hot pipe, thus rendering him unfit for his work in the woods for some weeks.

I could, were it not for taking up valuable space, enumerate instance after instance fully as peculiar as the above. In brief, it may be stated that at any time and under any circumstances, with the slightest provocation, and almost instantaneously on being spoken to, one of these fellows will obey any command, imitate any action, without regard to its nature, trivial or serious. He will leap on to a table, or over a stove, or into a river or pond; throw any article or weapon he may have in hand in any direction indicated; will repeat any sentence or exclamation.

So serious a matter is this that many of the lumbermen absolutely refuse to admit a man known as a "jumper" into their camps.

I find they are not wholly confined to French-Canadians, as occasionally a Canadian of Irish parentage will exhibit the same symptoms.

As stated above, I have endeavored, when possible, to investigate as to the cause of this peculiar and distressing condition; and while I find, without doubt, that primarily it is due to an inherited nervousness, the immediate cause is in taking such children, when small, and while firmly held tickling them until convulsive symptoms appear. This seems to be the story of such ones as I have made inquiries of. Whatever the cause, the condition is one much more easily acquired than lost, as it firmly clings to its victim far into adult life.

J. B. THORNTON, JR., M.D.,
Sanitary Inspector U. S. Marine Hospital Service.

MOOSE RIVER, SOMERSET COUNTY, MAINE,
November 30, 1885.

BROTHERLY LOVE IN MEDICINE AND A MEDICAL ARCADIA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In these days of complaints about the abuse of medical charities, resignations from the International Medical Congress, Code discussions, and heart-burnings consequent upon the overcrowding of our professional ranks, it may be profitable to some to glance at what we here, in our innocence, consider to be the "Banner Medical County" of the United States. I refer to Boulder County, Col.

Our county contains less than 12,000 inhabitants, the largest town in it having 300. To attend to the medical wants of the county we have twenty-one legal practitioners (that is, legal either by diploma or license of the State Board of Medical Examiners), some four or five medical guerillas, several midwives, and a few retired medical gentlemen. These all manage to live in a comfortable manner, but for fear that others may wish to rush in and divide our blessing, I will state that we also have a Medical College in full blast, mostly run by outside physicians, so are able to fill all vacancies that may occur in our ranks.

Judging from this condition of affairs, you might infer that we have a "pretty kettle of fish to fry." Nothing of the kind. We have a regular Medical Society, which meets twice a year; there we discuss practical questions, or, if a member chooses, he reads a paper, being careful not to bore the rest with extracts or a rehash of what each man has in his library, and with which he is presumed to be fully acquainted. When disposed, we lighten the heavy work by sly jokes at each other's expense.

As to the subject of medical charity, we all have a number of charity patients, among them are dead beats whom we cannot eliminate; these occupy as much of our time as the average city practitioner gives to his hospital work. But should one of our number manifest a disposition to monopolize more than his share of this kind of work, we don't hold indignation meetings; not much; on the contrary, we all go out of our way to send him dead beats and charity cases until he is satisfied.

Under the operations of an unwritten by-law no Code discussions are permitted. Each member consults with whom he pleases, and is never required to justify himself by special pleading of "an emergency," or "for diagnostic purposes only."

Again, if a member fancies that he has a grievance against a brother, he is, by the operation of another unwritten by-law, forbidden to make a battle-ground of the Society meeting; our purpose of meeting is to have a good time socially as well as professionally, and we succeed.

PERFECT BLISS, M.D.

DYSIDROSIS OF THE FEET.—Mr. W. Whitworth advises that two pieces of common adhesive plaster be cut, of the same shape as the flat of the feet, and applied to the soles. Sweating and malodor will speedily cease.—*British Medical Journal.*

Reviews and Notices.

MINOR SURGICAL GYNECOLOGY. A Treatise of Uterine Diagnosis and the Lesser Technicalities of Gynecological Practice, including General Rules for Gynecological Operations and the Operations for Lacerated Cervix and Perineum, and Prolapse of Uterus and Vagina, for the Use of the Advanced Student and General Practitioner. By PAUL F. MUNDÉ, M.D., Professor of Gynecology at the New York Polyclinic and at Dartmouth College; Gynecologist to Mount Sinai Hospital, etc. Second edition, revised and enlarged, with three hundred and twenty-one illustrations. 8vo, pp. 552. New York: William Wood & Co. 1885.

THE second edition of this excellent work is before us, presenting many additions to the first edition, including rules for the governing of gynecological operations in general, and a minute description of the operations for laceration of the cervix and perineum, and prolapsus of the uterus and vagina. As the book is principally intended for beginners, the various methods of examination and diagnosis are very thoroughly studied. This part of the work will prove of great aid to the student, as success in gynecology results from a close attention to details, which is sometimes overlooked by the general practitioner. It is said that the last achievement of a science is to define itself; this may explain the difficulty of gynecologists in agreeing upon the exact position of the uterus. Concerning this vexed question the author explains that with every variation in intra-abdominal pressure during inspiration and expiration, and voluntary motions and positions of the body, the fundus and body of the uterus vibrate back and forth, like a pendulum, with its pivot at the reflection of the vagina on the cervix. A diagram is given showing the degrees of normal mobility of the uterus, with its average normal position. The student is thus enabled to begin the study of displacements with some degree of intelligence. The usual rather formidable array of pessaries is given, with plates; but a set of rules governing their introduction and supervision may lessen to a certain degree the perplexity of this subject to the beginner. It is not necessary to notice other points of value in this work. For those starting out upon the study of gynecology, and even for students more advanced in knowledge of the science, the book will prove invaluable. Good illustrations and a clear type enhance the value of the work.

THE MEDICAL NEWS VISITING LIST FOR 1886. Philadelphia: Lea Brothers & Co. 1885.

"IF the office of a visiting list is," to quote from the Preface, "to enable a physician to keep a clear record of his engagements and of his professional work," this list of the *Medical News* is certainly a model in its way. In addition to spaces for records of visits made, it has the usual tables of poisons, doses, etc., together with pages for addresses of patients, nurses, and all others whose whereabouts might be of interest to the physician. A thumb-letter index facilitates the work of reference. The volume is compact and complete, and a credit to the printer's and binder's art.

MICROSCOPICAL TECHNOLOGY, FOR USE IN THE INVESTIGATIONS OF MEDICINE AND PATHOLOGICAL ANATOMY. By DR. CARL FRIEDLÄNDER. Translated by STEPHEN YATES HOWELL, M.A., M.D., Buffalo, N. Y. New York and London: G. P. Putnam's Sons. 1885.

As the matter now stands, this volume is in competition with one published by another firm, and from another translation. The intrinsic merit of the two translations is practically equal. This book differs from the other in that it contains additional matter furnished by the translator, and also that it has no index. The material added by Dr. Howell is very acceptable, and enhances the value of the book. The merit of Friedländer's writing goes

without question, and does not require special reference, other than to say that it is concise, comprehensive, and scientific.

The house, however, that will publish such a work, or any work which is likely to be used as a book of reference, without giving it a complete index, ought to close business. Such an omission is inexcusable, and will provoke members of the medical profession unduly to the use of "swear words."

The excellence of the text is too great, and the translation is too excellent to be subjected to such a mutilation.

The Italian Medical Congress.—The Eleventh General Congress of Italian physicians, held in connection with the meetings of several hitherto independent medical societies, was convened in Perugia during the third week of September, 1885. Over three hundred of the representative medical men of Italy were present. At the opening session addresses were made by Professors Madruzza, Toscani, and Corradi, and by the Mayor and Prefect of Perugia. At the other general sessions addresses were made by Dr. Zucchi, who urged that the direction of matters of sanitation and public hygiene be confided to the medical profession; by Professor Pagliani, who advocated the passage of a bill regulating the hours of labor and the nature of the employment of women and children; and by Professor Pacchiotti on "Quarantine," in which the speaker argued against the establishment of land quarantine and sanitary cordons, and the fumigation of travellers and of mail matter. In the Section on Practice of Medicine, Dr. Paoletti read a paper on "Cholera," in which he endeavored to explain all the symptoms of the disease by the occurrence of spasm of the non-striated muscular tissues (arterial and intestinal), and stated his belief that the affection was a neurosis allied to tetanus. This view was strongly opposed by Professor Levi and others. Professor M. R. Levi related two cases of "Diphtheritic Nephritis," in which the morbific principle was located primarily in the epithelium of the glomeruli and tubules of the kidney. He regarded these cases as analogous to primary scarlatinal nephritis, and contended that they were an evidence that diphtheria was a general disease with local manifestations. This opinion was sustained by the majority of the speakers taking part in the discussion. Dr. A. Bianchi read a paper on "Auscultatory Percussion," exhibiting the instruments employed by him and demonstrating the application of the method on the living subject. Dr. Olivieri presented a communication upon the "Abortive Treatment of Typhoid Fever by Means of Intestinal Irrigations with Carbolized Water." He was opposed by Professor Levi, who pointed out the danger of poisoning from carbolic acid, and said that he had little faith in the efficacy of this drug, given either by the mouth or by the rectum, as a specific in typhoid fever. Professor M. R. Levi followed with a paper on the "Treatment of Diphtheria," in which he spoke very strongly in favor of oil of turpentine, given internally and by inhalation. As adjuvants he employed cold applications, lime-water, and lactic acid. Quinine and tonics were given internally when indicated. He advocated tracheotomy whenever death from suffocation was threatened. Professor Maragliano read a paper on "Antipyresis and Antipyretics," in which he expressed a decided preference for thallin over antipyrin, asserting that its action was more rapid and that it was effective in smaller doses. But he preferred baths and the application of cold externally to any of the internal antipyretics. In the ensuing discussion considerable stress was laid upon the danger resulting from the action of the antifebrile drugs in preventing the elimination of urea and carbonic acid, and a general preference was expressed for external antipyretic methods. Professor Riva spoke upon the "Treatment of Tuberculosis by Intrapulmonary Injections." He had found the lung-tissue very tolerant of these injections, but did not think the treatment exerted any curative influence upon the disease, although it had some effect upon the course of the fever. Dr. Magliero spoke of the efficiency of "Lemon-juice in the Treatment of Malarial Diseases," and Dr. Moretti related a case of a contagious "Dermatosis of the Lower Lip" somewhat resembling eczema. Dr. Nosotti said the eruption was very like that of epizoötic aphthæ, and he thought that probably the disease in question had been communicated from an animal. Dr. Balestrieri related several cases of "Tetanus" cured by the use of tartar emetic. Dr. Ascenzi exhibited an apparatus for the inhalation of compressed or rarefied air or of medicated vapors. Dr. Pagliani presented a short communication upon the "Treatment of Sciatica," in which he spoke of the good effects of strong sinapisms and baths of dry hot air. Dr. Dal Fabbro related a case of "Traumatic Cerebral Affection," in which the symptoms were corroborative of the present theories of motor localization in the cortical centres. Dr. Queirola read a paper on the "Physical Examination of the Spleen," demonstrating the changes in the area of splenic dulness occasioned by the different postures assumed by the patient. Dr. Bianchi spoke of the uses of the "Juice of the Fig," and explained the method of its preparation. He said that it possessed the power of digesting fibrin and albumin, and might be used with benefit in dyspepsia from deficient secretion of the gastric juice. In the Section on Surgery Professor Ceccherelli read a paper on "Tubercular Osteitis and Arthritis," which gave occasion to a somewhat animated discussion. Professor Durante presented a patient from whom he had removed a tumor of the dura mater, situated at the base of the skull on the left side. Entrance to the cranial cavity was obtained through an opening made in the left parietal bone. Professor Laurenzi sent a report of various operations performed by him, comprising laparotomy, resection of the knee, ligature of the carotid artery, and an operation for empyema. Professor Ceci related an operation for the "Extraction of Calculi from the Left Ureter," and Professor Massei reported several cases of "Erysipelas of the Larynx." Professor Occhini sent a communication entitled "Properitoneal Hernia," and Professor Chiari read a paper on "Hysterotomy for the Removal of Multiple Fibromyomata of the Uterine Appendages." Many of the papers presented elicited prolonged discussion. In the Section on Obstetrics and Gynecology papers were read by Professor Chiari on "Puerperal Antisepsis as Practised in the Obstetrical Institute at Florence," and upon a case of "Continuation of Pregnancy after Puncture of the Amniotic Sack and Evacuation of the Fluid." Dr. Borsini related a case of "Partial Ovariotomy." The patient was seventy-six years of age, and the operation was successful in its results. Dr. Piccinini read a paper on the "Treatment of Myomata of the Uterus." He employed the continued current, and

gave ergotine internally. Dr. Fibbi reported a case of "Cæsarean Section." The operation was rendered necessary by dystocia due to a fibroma of the uterus. Professor Fabbri read a paper on "Dropsy of the Amnion," relating three cases of the disease, and discussed the origin of the amniotic fluid. Dr. Mori presented a communication on "Uræmia as a Complication of Pregnancy," and advocated hypodermic injections of citiate of iron in the treatment of this affection. There were other Sections on Hygiene, Anatomy, and Physiology; Syphilis and Diseases of the Skin; Pharmacy and Psychiatrics, and Legal Medicine. In the general conferences papers were read by Professor Pagliani, on the "Best Systems of Sewerage in Cities;" by Dr. De Medici, on "Cremation;" by Dr. Simoncini, on "Evolution in the Education of Man;" and by Dr. Nomi, on a "Method for the Preservation of Cadavers." At the closing session it was resolved to form a permanent union of the various independent societies which had taken part in the congress. Pavia was selected for the next meeting, to be held in 1887.—*Lo Sperimentale*, No. 10, 1885.

To Increase the Efficiency of the Paquelin Cautery.—Dr. M. S. Kakeles, of New York writes: "The use of the Paquelin apparatus for cauterizing purposes cannot be overestimated, and in many cases is far superseding the expensive Galvano-cautery. To increase its efficiency the air-chamber of the now almost universally used spray apparatus is utilized instead of the ordinary rubber hand and air bulb. Its simplicity and convenience for office work is so far superior as to be immediately apparent to all who will give it a trial. It has been used in several cases in Dr. Alex. Hadden's office in operations for the removal of nævi, and with such good results as to call forth admiration of its applicability, and at the same time the condemnation of the tiresome hand apparatus. By merely connecting the benzine receptacle with the rubber tube from the air-chamber, we have a reservoir of compressed air at the immediate control of the operator. He can easily increase or diminish the quantity of air by a valve attached to the tube, and thus regulate the intensity of heat in the platinum point. So convenient is it, and its manipulation so easy, that after once it is used it will always be preferred to the wearisome hand bulb. Its practicability consists in that: 1. We have a reservoir of air of sufficient amount for quite a lengthy operation, confined at any pressure and under the control of the operator himself, which obviates the necessity of an assistant to work the hand bulb in order to keep up a constant glow. 2. We can regulate the pressure by the stop-cock attached to the tube, and thus keep up an equal temperature in the platinum point, or increase or diminish it. 3. A single person is only necessary to use the apparatus, by merely regulating the intensity of the heat by turning on the valve to a certain degree and allowing the air to blow through the Paquelin. Certainly, in operations at private houses, it would not be very convenient to carry a large air receiver along with the Paquelin instrument, but for office, hospital, and dispensary use there is no readier or more convenient apparatus for cauterizing purposes.

Ideal Cholecystotomy.—Dr. A. C. Bernays, of St. Louis, Mo., writes: "In your notice of my paper on 'Ideal Cholecystotomy,' you say that I report a case of cholecystotomy 'upon which he bestows the epithet "ideal," for various reasons sufficient unto himself.' I desire to correct this misunderstanding, and to make the following short explanation: Sims' method of cholecystotomy necessitates the formation of an abdominal biliary fistula. It exactly copies after nature in her efforts to effect a spontaneous cure of cholelithiasis. I called *this method* 'natural' cholecystotomy. The method employed by me does away with the abdominal fistula, and causes an immediate *restitutio ad integrum*. I called this method '*ideal*' cholecystotomy. It perfectly fulfils all that we can ask of the surgical art, in contradistinction to the method which imitates the healing process of nature but leaves the parts in an abnormal condition even after the fistula has become closed. Since the publication of my paper I have received accurate descriptions of the only two cases where a similar operation was supposed to have been performed successfully before. It so happens that my case is the only successful one up to date, the case by Courvoisier ended fatally some weeks after the operation, and the Bebbs case was not a cholecystotomy at all, but seems to have been a removal by abdominal incision of some gall-stones, which had perforated the gall-bladder and had become encysted after adhesions had been formed by a circumscript peritonitis. Finally, I may be allowed to express my pleasure at having placed American surgery one step in the van in a new field of our art."

Toxic Action of Cocaine.—Dr. Ziem, of Dantzic, has communicated to the *Allgemeine Medicinische Central-Zeitung* the notes of a case in which he applied two drops of a four per cent. solution of cocaine to the eye of a man aged forty. In a few minutes after the pupils had become dilated, the patient's face became pale, sweat broke out on his forehead, and his breathing became embarrassed. Dr. Ziem at once loosened his clothes and opened the window, but it was a quarter of an hour before he could return home. The man's wife said that he had not previously had syncope. He was of intemperate habits, and some years ago had been treated for disturbances of motor power in the lower limbs, apparently connected with syphilis. Dr. Ziem says that seventeen cases have been recorded in ophthalmological literature in which toxic effects followed the use of cocaine. In three it was injected hypodermically, and in fourteen dropped into the conjunctival sac. The cases have been described by Peck (1), Mayerhausen (1), Stevens (1), Reich (2), Knapp (3), Heuse (4), and Bellarminoff (5). In some cases the symptoms have been transient, consisting of pallor of the face, giddiness, and sweating of the face or neck; in others there have been dyspnœa, great feeling of prostration, malaise, and apathy, lasting sometimes for several days. Vomiting and headache have been rarely present. In one case the application of fifteen drops of a two per cent. solution to the conjunctiva was followed by tottering gait, difficulty of speech, confusion of the mind, and extraordinary restlessness; and in another the subconjunctival injection of about eight drops of a 3.5 per cent. solution produced convulsions and loss of consciousness. The strength of the solution used was four per cent. in eight cases, 2.5 per cent. in four, and two per cent. in three or four others. The quantity generally varied from two to four drops. The subjects were in some cases feeble, aged women; in others they were strong and healthy individuals, both male and female.—*British Medical Journal.*

Reduction of Temperature by Ice-bags.—Dr. F. A. Burrall, of this city, writes to the *Journal of the American Medical Association*: "Stephan, of St. Petersburg (see *Journal*, September 26, 1885), is of opinion that the temperature in fever may be lowered by the application of ice-bags over the superclavicular region. This effect is produced by bringing the cold in contact with the large superficial veins of the neck. I have noticed that in some cases of pneumonia a sensation of intense heat is one of the most trying sensations from which the patient suffers. In two of my cases much relief was afforded by the continuous application of the ice-bag to the occipito-cervical region. One of the patients told me 'it was the only comfort he had.'"

What Becomes of the Medical Students.—Our English exchanges inform us that Sir James Paget has been studying the question of what becomes of the medical students. Some statistics are given which are hardly to the purpose. Evidently Sir James has never watched the medical students slip round the corner at the close of lecture.

Progress of Medical Science.

The Non-tuberculous Nature of Lupus.—The following are the conclusions of Dr. Gamberini, in an article on this subject appearing in the *Giornale Italiano delle Malattie Veneree e della Pelle*, Nos. 3 and 4, 1885: 1, Lupus is not identical with tuberculosis; 2, even if tubercle is found in the tissue attacked by lupus, it does not necessarily follow that tuberculosis is the cause of the degeneration, for bacilli have been only occasionally found here, while they are abundant in tuberculous tissues; 3, experiments upon rats do not bear out the theory of identity of causation of the two diseases; 4, the differences exhibited in the response of the tuberculous and the lupus ulcerations to therapeutic measures is very striking; 5, lupus and the tuberculous skin affections are very dissimilar in their symptomatology and cause.

A New Disease.—Dr. Lutz has observed in the province of San Pablo, Brazil, several cases of a peculiar disease, of which he has never seen a description. It begins with vomiting and diarrhœa, hoarseness and a cough, and frequently coryza and catarrhal conjunctivitis. Then appears œdema of the skin, accompanied sometimes by ascites and a peculiar dermatitis, under the form of an erythema; invading first the lower parts, and then spreading over the whole body in patches of variable extent. This erythema does not disappear under pressure of the finger, and becomes gradually of a dark purple color, and finally black. Desquamation takes place in large strips, leaving a tender epidermis, which, in the negro, is without color. There is fever at the commencement of the disease, and grave anæmia occurs as a sequela. The duration is several months. It begins generally with symptoms of gastro-enteritis, or of bronchitis, and œdema and ascites appear only after several weeks. Of 23 cases seen by Dr. Lutz, 10 died, 6 recovered, and the result in the others was unknown. The disease affects chiefly infants who have been weaned, and is probably due to some special food. The author states that it bears considerable resemblance to pellagra.—*La Independencia Médica*, November 11, 1885.

Cancer of the Liver and Pancreas in an Infant.—Dr. Bohn reports the following case: "The child was born of healthy parents, and presented nothing abnormal during the first half-year of life. At the beginning of the seventh month the mother accidentally discovered a spot of induration, about the size of an apple, in the abdomen, which increased with great rapidity, so that within three or four weeks the tumor filled the greater part of the abdominal cavity. When the tumor was first discovered the health of the child seemed to be unaffected, but emaciation soon commenced, and during the few days immediately preceding death there was intense icterus, and the limbs and abdomen were covered with petechiæ. The child died within two months after the discovery of the tumor. The autopsy revealed primary cancer of the pancreas, with secondary infection of the liver and retroperitoneal lymphatics. The pancreas was almost entirely destroyed, the head only exhibiting some remains of glandular tissue. About the portal vein was a collection of enlarged glands, and on the surface of the liver, as well as within its substance, were numerous white, hard nodules, varying in size from that of a pea to that of a plum. Examination showed the new formation to be a typical carcinoma simplex.—*Wiener Medizinische Wochenschrift*, November 7, 1885.

Pemphigus Neonatorum.—Dr. Plomberg reports the case of a girl, six days old, who presented numerous little blisters, from the size of a hemp-seed to that of a hazel-nut, upon the genitals and neighboring portions of the thighs. Gradually the eruption spread over the entire body, being very thick over the four extremities, the face, and the scalp, and somewhat more thinly scattered over the trunk and neck. The entire sole of the right foot, with the toes, was involved in one large bulla, and after this had broken the epidermis came away like a glove. Two smaller blebs were present on the sole of the left foot, but the palms of the hands were free. The blisters rapidly attained their full development, and burst after two or three days, giving exit to a yellow serum. They were surrounded with a pale reddish areola, and after breaking left the denuded corium red and moist. The excoriations healed rapidly, crusts forming only on the face.—*Wiener Medizinische Wochenschrift*, November 7, 1885.

Treatment of Favus in the Adult.—The crusts should first be removed by lotions of green soap, preceded, if necessary, by poultices. The hair is then to be cut as short as possible, and an ointment of 8 to 15 grains of bichromate of potassium in one ounce of lard applied, the head being afterward covered with a cap of linen or cotton cloth. The head should be thus washed with green soap, and covered with the ointment every morning and evening. If the application cause much smarting the proportion of potassium bichromate should be reduced, or if the crusts fail to become detached it should be increased. A trial of a few days' duration will suffice to determine the relation between the individual tolerance and the degree of activity of the ointment. The hair should be cut very close, but epilation is useless.—*Journal de Médecine de Paris*, November 15, 1885.

Hæmatemesis following a Superficial Burn.—Professor Demme reports the case of a strong, healthy boy, five years old, who received a superficial burn of the left forearm and hand. The epidermis was raised in blisters on the wrist and extensor surface of the forearm, but there was no destruction of the deeper cutaneous tissues. A liniment of linseed-oil and lime-water was applied. Six hours after the receipt of the injury the patient vomited some milk which he had taken an hour before. An hour and a half later he vomited suddenly a quantity of mucus strongly colored with blood, and the hæmatemesis recurred frequently during several hours, the loss of blood being so great as to threaten the life of the child. Eighteen hours after the burn was received another attack of vomiting occurred, and the patient went into collapse. The temperature fell within two hours from 101° to 94° F., and the pulse became so rapid that it could not be counted. The face and extremities were cool, and covered with a clammy sweat, and the pupils were dilated. The feet and legs were covered with mustard plasters, and ether was injected hypodermically every half hour. The patient gradually recovered his strength. During the succeeding days there were several copious stools of altered blood.—*Wiener Medizinische Wochenschrift*, November 7, 1885.

Recovery from Traumatic Tetanus.—Dr. Rangé reports the case of a man whose foot was amputated on May 3d on account of osteitis. The case progressed favorably, and cicatrization was nearly complete on the 18th of May, when he complained of inability to open the mouth. There was no elevation of temperature, and the wound looked well; but the patient was not very docile and persisted in flexing the leg, thus rubbing the soft cicatrix at the end of the stump against the bed-clothing. The rigidity of the muscles of mastication and of the neck persisted, with some remissions, for a week, when general tetanic spasms set in. An attempt was made to give morphine hydrochlorate hypodermically, but the act of inserting the needle excited fresh convulsions, so the solution was used endemically, being applied to the stump. The trismus having subsided, chloral and bromide of potassium were given internally. It was impossible to isolate the patient, but in spite of this inconvenience improvement began in a few days, and by the end of the month recovery was complete.

Collins, Dr. Isaac G., death of, 708.
Coma, diabetic, and acetonæmia, 232.
Comingor, Dr. J. A., acute epididymitis, 433.
Comma bacillus, 16.
Conception, after scraping the uterine cavity, 516 ; artificial, 420 ; while the uterus contained a placenta, 651.
Congress of German Naturalists and Physicians, 555.
Conium, poisoning by, 293.
Conjunctiva, compressible tubes for applying ointments, 277 ; gumma of the, 513 ; herpes iris affecting, 308 ; new instrument for washing the cul-de-sac of, 251.
Conjunctivitis, contagious, 24.
Constipation, 173 ; cascara sagrada in, 66.
Consumption, pulmonary, treatment of, 532 ; tubercular, 577.
Contagious diseases, penalty for reporting, 602, 708.
Contracture, 69.
Convallaria maialis, 196, 295.
Conversation-tube, binaural, 503.
Convulsions, puerperal, without albuminuria, 290.
Conway, Dr. J. R., cocaine in fracture, 541.
Copper and scrofula, 652.
Coracoid process, osteitis of, 517.
Corn, the, 483. 514.
Corns, 221.
Corset, the. 342.
Coryza, infantile, 336.
Cotterel, Dr. Edward, book notice, 76.
Cough, 253 ; the convulsive, of childrer, 460.
Cowan, Dr. Geo., trachelorrhaphy forceps, 139.
Craft, Dr. J., cocaine and corneal opacity, 12.
Craniotomy, 668 ; the ethics of, 492 ; Roman Catholic view of, 606.
Crawford, Dr. A. H., prolonged gestation, 195.
Cremation, 188, 408.
Croaking, respiratory, of babies, 293.
Croup, membranous, 617, 638 ; subcutaneous, emphysema in, 664 ; tracheotomy in, 648.
Cul-de-sac of the conjunctiva, 251.
Curette, new pharyngeal, 670.
Curtis, Dr. H. Holbrook, post-nasal cutting forceps, 446.
Cyanosis, congenital, 498.
Cyst, branchial, 87, 598 ; perinephritic, 701 ; peri-rectal dermoid, 222.
Cystitis, 654 ; exfoliative. 497 ; necrotic, 667.
Cysts of the Pancreas, 125.

D

Dadiraian, Dr. Mankan G., cholera, 61.
Damiana, 200.
Dana, Dr. C. L., acro-neuroses, 57, 85.
Davis, Dr. John Staige, notice of death of, 104.
Davos, an American, 262.
Dayton, Dr. William A., pharyngeal curette, 670.
Deafness, classification of pupils, 58.
Death from the sting of a bee, 290.
Death-rate of war, 44.
Decidua, 318.
Defoe, Dr. S. A., melancholia, 683.
Deformities, inheritance of artificial, 474.
Deformity, of the feet and hands, congenital, 220
Delavan, Dr. J. Savage, notice of death of, 186.
Delirium tremens, 460.
Dellenbaugh, Dr. Z. P., convallaria, 196.
Demagogues, in medicine, 196.
Denslow, Dr. Legrand N., urethral irritation, 511.
Dentistry, ancient, 28.
Dentist's leg, 542.
Derma, structure of, 331
Dermatolysis with molluscum fibrosum, 459.
Dermoid cyst, of the ovary, 498 ; pin rectal, 222.
Diabetes mellitus, 441 ; buckwheat flour in, 280 ; in India, 11.
Diarrhœa, chronic, albumin in, 321 ; infant, and thermic fever, 154 ; of children, 243 ; of consumption, 532 ; resorcin in, 541 ; so-called fatty, 152 ; the summer, of infants, 402.
Diazor-benzol, 635.
Dickinson, Dr. W. Howard, book notice, 468.
Diet in hot weather, 101.
Digestion, pancreatic, 302.
Digitalis, 504 ; cumulative action, 40.
Diphtheria, 73, 106, 109, 177, 556. 610, 637, 698 ; and croup, 163 ; and its management, 617 ; puerperal, 356.
Disease, a new, 717.
Diseases, nomenclature of, 80.
Disinfectants, 37, 137, 304, 643 695.
Disinfection, of rags. 464 ; of sleeping apartments, 278.
Dislocation of the finger, 541 ; of the first cervical vertebra, 257 ; subcoracoid. 360.
Dispensaries, 184 ; free, 699 ; not wanted, 687.
Doctor and his spiders, 409.
Doctors, American supply of, 708 ; bills. 604 ; field for young, 669 ; peculiar danger. 684.
Dogwood, Jamaica. 295.
Doubleday, Dr. E. T., typhoid fever, 505.
Downey, R. C., opium habit, 699.
Drainage of ulcers and surface wounds, 375.
Draper, Dr. John C., book notice, 211 ; death of, 709.
Dropsy, lactuca graveolens in, 473.
Drugs, action of, at a distance, 464 ; investigations regarding some new, 294.
Drunkards, criminal responsibility of, 179.
Dudgeon, Dr. John, and his work in China, 707.
Duffy, Dr. C. C., effects of alcohol on the liver, 346 ; salicylate of iron in rheumatism, 38.
Dugan, Dr , 204.
Duggan, Dr. J. R., disinfectants, 304, 695.
Duncan, Dr. Charles G., tape-worm and chloroform. 12.
Dundakine, 514.
Duodeno-cholecystotomy, 53.
Duodenum, perforating ulcer of, 358.
Dupuytren's contraction. 652.
Dysentery, local treatment of chronic, 636.
Dysidrosis, 330.
Dysmenorrhœa, 458.
Dyspepsia, 97 ; hydrastis in, 652.

E

Ear, diseases of complicating scarlet fever, 106; maggots in, 257; middle, fibroid tumor of, 400.
Echinococcus of the liver, 415.
Eclampsia, puerperal, 180; puerperal, inhalation of oxygen in, 151.
Eclectics, 547.
Edson, Dr. Benjamin Ferrán's experiments, 53.
Eggs, for sick, 119.
Eichberg, Dr. Joseph, typhoid fever and acute tuberculosis, 480.
Electricity, and dust, 698; as a therapeutical agent in gynecology, 553; in dilatation of the stomach, 377; in pelvic cellulitis, 627; static, 465, 504; static, new apparatus for generating, 447.
Electrotypes, human, 588.
Eliot, Dr. Llewellyn, abortion and fresh paint, 560; poisoning from the internal administration of chloroform, 29; the metric system in medicine, 426.
Elsberg, Louis, M.D., memoir of, 693.
Embolism, 663; cerebral, 568.
Emerson, Dr. J. B., a schematic eye, 399.
Emmet's cervix operation, 387.
Emphysema, pulmonary, 654; subcutaneous, in croup, 664.
Enchondroma, of the jaw, 360.
Endocarditis, acute, 556; ulcerative, 221, 358.
Endowments for medical institutions, 294.
Enteritis, surface temperature of abdomen in, 571.
Enterocele, vulvar and vaginal, 712.
Enuresis, and rhus toxicodendron, 96, 306; scutellaria in the treatment of, 204.
Epididymitis, acute, 40, 433.
Epiglottis, œdema of, 177.
Epilepsy, 235; and ear disease, 458; and motor functions of the cortex, 112; and nasal polypi, 204; nitrite of sodium in gouty, 513, rheumatic, 68; the viscera in, 349.
Epistaxis, 307.
Epithelium of the eyelid, 190; of the penis, 469; of the tongue, 109.
Eruptions, from certain medicines, 700.
Erysipelas, 136, 348; and borated vaseline, 652; etiology of, 152; microbe of, 111; relief of the burning pain, 356; repeated attacks, 600.
Erythema exudativum, 415.
Ether, as an intoxicant, 570; danger of subcutaneous injections of, 631; narcosis, 79.
Etherization during sleep, 462.
Euthanasia, 322.
Excision of the hip-joint, 164.
Exsection of the knee-joint, 219.
Extension, continuous, applied to the lower extremities, 489.
Eye, a schematic, 399; and spinal curvature, 697; changes in, in cholera, 293; transplantation of, 110, 361.

F

Face-wash, 188, 277.
"Faith Cure," 195.
Fall of 250 feet without severe injury, 459.
Fatality of charcoal fumes and illuminating gas, 392.
Faulkner, Dr. R. B., commissions from druggists, 504.
Favus, treatment of in the adult, 717.
Fecundity, remarkable, 277.
Feeding, artificial, in vomiting of pregnancy, 652; the sick, 115.
Feet, burning, 85; cold, 196; dysidrosis of, 714; hyperæsthesia of the soles, 321; sweating of, 697.
Femur, extra capsular fracture of the neck of the, 21.
Fenn, Dr. C. M., rectal absorption, etc., 173.
Ferrán, Dr., 129, 156; and cholera, 605; collapse of, 100; experiments of, 53, 274; inoculations by, 65.
Fever, blackwater, 289; puerperal, 214; scarlet, 105, 280, 382, 383, 493; scarlet, after treatment, 542; thermic, and infant diarrhœa, 154; typhoid, 505, 696; typhoid and acute miliary tuberculosis, 480; typhoid, danger of phenic-acid injections in, 601; typhoid, how to abort, 278; typhoid, is it ever of spontaneous origin? 499; typhoid, present aspect of treatment, 660; typhoid, spontaneous origin of, 584; typho-malarial, 530; urethral, 360; yellow, 409; yellow, and mosquitoes, 494; yellow, and quarantine, 671; yellow, and the efficacy of quarantine, 583; yellow, inoculation, 698; yellow, preventive inoculation, 298.
Fevers, starving, 461.
Fibroids, uterine, medical treatment of, 206, 502.
Fibro-sarcoma of the naso-pharynx, 241.
Fish-poison, 259.
Fistula, vesico-vaginal, 20, 39.
Fluhrer, Dr. W. F., wiring of bones, 340.
Foot, inversion of, 111.
Forceps, obstetric, 671; post-nasal cutting, 446.
Fothergill, Dr. J. Milner, bronchitis, acute and chronic, 225; asthma, 141; cough, 253; pulmonary phthisis, 197; notice of book by, 692.
Foveola Coccygea, 656.
Fowne's Chemistry, book notice, 524.
Fox, Dr. William, ovariotomy during acute peritonitis, 376.
Fracture, of the clavicle, 230; of the humerus, 230; of the larynx, 67; of the occipital bone, 242; of the patella, 258.
Fracture-box, 38.
Fractures, 131; in the aged, 697; of the upper extremities, 673, 693; spontaneous, 20.
Franklinism in medicine, 531.
Fraser, Dr. E. P., intra-vaginal syringe, 277.
Freckles, 332.
Free, Dr. Spencer M., International Medical Congress, 275.
Friedländer, Dr. Carl, book notice, 412, 417.
Fruit, 39.
Fruitnight, Dr. J. Henry, antipyrine and an eruption, 364.
Fuller, Dr. F. C., stretching the sciatic nerve for sciatica, 39; wiring fractured patella, 63.

G

Gaillard, Dr. D. L., rupture of the perineum, 39.
Gait of nervous people, 670.
Gangrene, pulmonary, 517; symmetrical, of the extremities, 542.
